"WHOLESALE ELECTRICITY."—This is the somewhat novel title of an article in last Monday's *Times*. The writer gave a brief review of the plan upon which Mr. Moulton has drawn up the provisional orders, which were entrusted to his care. As we have already treated this subject in our columns we need not refer to it at any length here.

ELECTRIC LIGHTING AT BOLTON (LANCS.).—The first permanent installation of incandescent lighting in Bolton took place on Monday, the 22nd inst., at the cotton mills of Messrs. Haslam and Co. The dynamo used is one of Siemens's shunt-wound machines, and the lamps are Swan's 20 c.-p. The installation has been carried out by Mr. William Banks, electrician, of Corporation-street, Bolton.

ELECTRIC LIGHTING IN SOUTHWARK.—The St. Saviour's District Board of Works, Southwark, after careful consideration of the draft provisional order now being applied for by the Metropolitan Brush Electric Light and Power Company has resolved not to offer any opposition to the granting of the same by the Board of Trade. This is the first instance of the kind under the Electric Lighting Act, at least in London.

ELECTRIC LIGHTING IN BRISTOL.—A wholesale and retail grocer, Mr. R. S. King, of West-street, St. Phillip's, Bristol, has adopted the electric light for the illumination of his shop and warehouse. Forty-five Swan incandescent lamps are employed, the current being supplied by an S.D. 7 Siemens dynamo, driven by a 4 h.-p. steam engine. The switches and fittings were supplied by Mr. H. E. Kear, of Redcross-street, Bristol.

THE MUNICH EXHIBITION.—We have received an official document of thanks from the committee of this exhibition, which is very neatly got up. It contains an illustration of the interior of the "Glas Palatz," where the exhibition was held, with an ornamental cover, and is signed by the members of the committee. This document will be appreciated by English journals as a courteous acknowledgment of their services by our fellow workers in Germany.

Digitized by Google

THE TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—On Wednesday week the Streets Committee of the Commission of Sewers visited the works of this company at Greenwich, and were met by Mr. Willoughby Smith, the electrician. The works are now open day and night for the purpose of making the Red Sea cable, and are wholly lighted with the Swan incandescent light. The committee were much interested in Gordon's large dynamo, which we illustrated and described in a recent issue.

ELECTRIC LIGHTING FOR CANTERBURY.—The question of the introduction of the electric light into this city, which has for some time engaged attention, was again the subject of debate on Wednesday last. The Town Council held a long consultation with the managing director and solicitor of the South Eastern Brush Company, but the consultation was unsuccessful, and the parties separated without coming to terms. A special meeting of the council was afterwards held, at which it was decided that in order to protect the city from monopoly a number of the clauses in the provisional order for which the company is about to apply should be opposed.

ELECTRIC LIGHTING IN COLLIERIES.—We recently mentioned that Messrs. Bell Brothers had adopted incandescent lighting for their Page Bank Colliery in South Durham. The whole of the lights were successfully started last week. They are worked on two circuits—"the long-hour," or all night, and the "short-hour," or day circuits, comprising 37 and 64 Maxim incandescent lamps respectively. The current is supplied by two dynamos. Messrs. Harle (manager) and Clough (engineer to the colliery) have also had a few lamps fitted in their houses. The work has been carried out by the Maxim-Weston Electric Company, of 47, Cannon-street, E.C.

ELECTRIC LIGHTING AT THE HOLBORN RESTAURANT.—The Holborn Restaurant, which has been thoroughly remodelled and enlarged, will, when opened, be lighted by the Edison electric light. Messrs. Ransomes, Head, and Jefferies, of the Orwell Works, Ipswich, are building for this purpose two 16 horse-power engines, to be fitted with their patent automatic governor expansion gear, which has already given such excellent results in connection with the electric light. The whole arrangements are under the immediate control of Messrs. Lewis Olrick and Co., of 27, Leadenhall-street, E.C., consulting engineers to the Edison Company. The opening of this new installation, will, we understand, take place early in February.

ELECTRIC LIGHTING FOR THE CITY.—The Select Committee of the Commissioners of Sewers of the City of London are inviting proposals for lighting (only) portions of the City by means of electricity, with a view to applying to the Board of Trade for a license under the Electric Lighting Act, 1882. Each proposal must indicate on a plan the area or areas intended to be lighted, together with conditions of supply, including price, &c. No one area is to exceed an eighth of the whole city. The proposals must include the lighting of the public streets and private and other premises within the respective areas, and be subject to the provisions of the above-mentioned Act and the rules made by the Board of Trade. Proposals should be sent to Mr. Hy. Blake, principal clerk, Sewers Office, Guildhall, E.C., by the 3rd of February.

ELECTRIC LIGHTING AT BERECHURCH HALL.—During the week several letters have appeared in *The Times* referring to the lighting of Mr. Coope's mansion at Berechurch. "Enquirer" set the example by asking sundry questions as to whether it was necessary to start the engine before you could get one light, and whether you had to run it all the same if one or 200 lights were going, and more to the same effect. This Mr. Coope answered in the affirmative. Mr. Sellon contributed to the correspondence by advocating the use of secondary batteries, by means of which the constant running of the engine might be avoided and perfect steadiness of the lights ensured. In another issue of the same paper, Mr. F. Rogers asked Mr. Sellon to state "the cheapest and best plan of electrically lighting, say, a pair of semi-detached houses of the villa class."

ANGLO-AMERICAN ELECTRIC LIGHT COMPANY.—A notice in the *Gazette* of January 19 states that "in pursuance of Section 142 of the Companies' Act, 1862, a general meeting of the members of the above-named company will be held at No. 112, Belvedere-road, Lambeth, Surrey, on Wednesday, the 21st day of February, 1883, at four o'clock in the afternoon, for the purpose of having an account laid before them, showing the manner in which the winding up has been conducted, and the property of the company disposed of, and of hearing any explanation that may be given by the liquidator, and also of determining, by extraordinary resolution, the manner in which the books, accounts, and documents of the company, and of the liquidator thereof, shall be disposed of." This company must not be confounded with the Anglo-American Electric Light Corporation.

ELECTRIC LIGHTING AT SHEFFIELD.—We have received a copy of the report of Mr. Conrad W. Cooke, the consulting engineer, who was recently requested by the Corporation of Sheffield to advise them with respect to the carrying out of their provisional order. The space at our disposal this week will not permit of our printing this report, but we shall hope to give it in a future issue. As a somewhat erroneous impression is abroad concerning what Mr. Cooke really did advise, we extract the following sentences:—"I have in the earlier part of this report recommended the employment of electric lighting by incandescence for the *private* lighting of the district for the reasons already adopted. It must, however, be a matter for the subsequent consideration of the Corporation whether it will be advisable on their part or not to recommend to consumers the employment of any one system of incandescence lighting or special form of lamp."

JOINT STOCK COMPANIES.—The *London Gazette* for the 23rd inst. contains a long list of joint stock companies that were struck off the register at Somerset House on that date. It includes the following amongst others:—Electro-magnetic and Electro Plate Company, Gas Engine Electrical Apparatus Company, Ocean Telegraph Company (registered on 1st April, 1865), Railway Electric Engineering and Telegraph Works Company, Scottish Pilsen-Joel and General Electric Light Company, Telegraphic News Association, and the Universal Telegram Company (registered 28th Oct., 1864). Another notice in the same *Gazette* states that the following companies will be struck off the register at the end of three months from the above date, unless cause is shown to the contrary:—Allan's Transatlantic Telegraph Company, Economic Telegraph Company, Finsbury Telegraph Newspaper Company, Great Northern Electric Light Company, Oriental Telegraph Company.

LIPMANN'S CAPILLARY ELECTROMETER.—At the last meeting of the Glasgow Philosophical Society, Dr. M'Kendrick read a paper entitled "Note on a Simple Form of Lipmann's Capillary Electrometer." This instrument consists of a fine capillary tube containing mercury and dilute sulphuric acid so placed under a microscope as to show a junction of the metal with the acid. A fine platinum wire dips into mercury at each end of the tube, and feeble currents, or rather slight differences of potential, at once cause

Digitized by Google

a movement of the mercurial column. The form made by Dr M'Kendrick is simply a tube drawn out into a capillary and bent up at the ends, but it is extremely sensitive, showing the currents obtained from muscle, and other feeble currents known to physiologists. Specimens of the instrument were shown, and the oscillations of the mercury, magnified by a quarter of an inch objective, were projected on the screen by the lime light, so as to be visible to all present. Dr. M'Kendrick illustrated the sensitiveness of the instrument by various experiments.

INSTITUTION OF CIVIL ENGINEERS.—The council of this institution have arranged for the delivery at their rooms, in Great George-street, S.W., of a series of six lectures, on the applications of electricity, on the undermentioned Thursday evenings, at 8 o'clock:—Feb. 15, "The Progress of Telegraphy," by Mr. W. H. Preece, F.R.S., M. Inst. C.E. March 1st, "Telephones," by Sir Frederick Bramwell, F.R.S., V.P. Inst. C.E. March 15th, "The Electrical Transmission and Storage of Power," by Dr. C. William Siemens, F.R.S., M. Inst. C.E. April 5th, "Some Points in Electric Lighting," by Dr. J. Hopkinson, F.R.S., M. Inst. C.E. April 19th, "Electricity Applied to Explosive Purposes," by Professor F. A. Abel, C.B., F.R.S., Hon. M. Inst. C.E. May 3rd, "Electrical Units of Measurement," by Sir W. Thomson, F.R.S., M. Inst. C.E. Admission to these lectures will be as to the ordinary meetings of the institution, that is to say, members, associates and students will have the right of personal admission, and every corporate member will have the privilege of introducing one friend.

THE TELEPHONE IN MEXICO.—The Mexican Telephone Company was formed in New York on the 21st April, 1882, with a nominal capital of 1,000,000 dollars, in 10 dollar shares. It owns the exclusive rights of the instruments used by the American Bell Telephone Company and the Continental Telephone Company for Mexico. The company possesses and works the telephonic exchanges of Mexico and Guadalajura, and is constructing public and private lines in the States of Mexico and Jalisco. The remainder of the country is to be apportioned between sub-companies, of which the following have already been organised:—The Mexican Central Telegraph and Telephone Company, the Mexican Northern Telegraph and Telephone Company, the Mexican Pacific Telephone Company, the Chihuahua Telephone Company, the Durango Telephone Company, the Puebla Telegraph and Telephone Company, the Vera-Cruz Telegraph and Telephone Company. Installations have commenced in eighteen of the principal towns in Mexico.—*Bulletin de la Compagnie Internationale des Telephones.*

ELECTRICAL SAFETY LAMP FOR MINES.—A correspondent, in a recent issue, asked for some information concerning the premium that has been offered by Mr. Lever, M.P., for a portable electric safety lamp for use in mines. For the benefit of our correspondent and others, we may say that Mr. Ellis Lever's address is Culdeth Hall, Bowdon, Cheshire, and that he has agreed to hand over £500 to the Central Board of the Miners' National Union, to be paid to any one inventing such a lamp. It has been provided that the offer shall remain open throughout the current year, and that the adjudicators shall be composed of "three scientists, one to be selected by Mr. Lever, one by the Council of the Royal Society, and one by the Council of the Society of Arts, one person representing the mining engineers, chosen by themselves, and one person representing the workmen, chosen by the Central Board of the Miners' National Union." The above-mentioned reward is to be meanwhile invested in the names of three trustees, one of whom shall be Mr. Thomas Burt, M.P., the other two to be chosen by the Miners' National Union.

"THE OPERATOR."—Our New York contemporary, which has hitherto been known under the title of *The Operator*, has with the New Year adopted a longer and more comprehensive appellation. In future it will be known as *The Operator and Electrical World.* Concurrently with its assumption of an extended heading we find that it has enlarged its size. In its issue for the 6th inst., our contemporary extracts Mr. Smillie's first letter to us on microphonic contacts, and alludes to it as challenging the statements in Professor Blyth's paper in the *Proceedings of the Royal Society of Edinburgh*, which paper *The Operator* says it reproduced from the *Proceedings* of the above-mentioned society. The same paper, we may remark, was also published in *The Electrician* prior to its publication in *The Operator*, and it is a remarkable instance of how men's minds in different quarters of the globe may conceive and carry out the same thought, that when the issue of *The Operator* containing the above paper came to hand, we found that their engraver had made identically the same mistake in his woodcut that ours had. Here we have a fit subject for the investigation of the recently formed Psychical Research Society.

ELECTRIC LIGHTING IN LONDON.—The Electric Lighting Committee of the Strand Board of Works intend to formulate some conditions with reference to the introduction of electric lighting into their district, which are shortly to be laid before the Board of Trade. The conditions are somewhat as follow:—That only one company should come into the district; that it should light all the district; that any private person desiring a separate service might do so on arranging with the company; that the board should control the number of hours during which the lighting should be maintained; that the charges should be 10 per cent. on the capital employed.—It was suggested at the meeting at which these conditions were submitted, that the committee should be empowered, if necessary, to obtain the services of an electrical expert at a cost not exceeding 25 guineas.—St. Olave's Board of Works do not think it advisable to take any steps to obtain a license.—St. George the Martyr (Southwark) Vestry have contented themselves with drawing up a formal list of amendments which they will like carried out in the provisional order applied for by the Metropolitan Brush Company.—St. Luke's Vestry also require some amendments in the same company's order.

ELECTRIC LIGHTING IN CARDIFF.—The Great Western Electric Light and Power Company have established a station in Working-street, Cardiff, where they have established two engines of 60 horse-power each. The premises of the *South Wales Daily News* have been lighted by means of Brush arc lamps erected by this company. They have also recently lighted up the Commercial Dry Dock at Cardiff, for the Tyneside Engine Works, with 16 Brush lamps, the dynamo being driven by one of Marshall and Co.'s portable engines. The work was carried out, under the personal superintendence of Mr. Philip Jolin, M.I.C.E., managing electrician to the company, by Mr. Ballard, the head superintendent from Bristol. The lights are placed in and about the ss. "Rumney," now under repairs. We are told that the lighting is satisfactory, and much appreciated. With reference to the dispatch with which this latter work was carried out, we may mention that the order was only received at the company's station in Bristol on Thursday afternoon, the 11th inst, and that the dynamo machine was packed and left Bristol on Friday; the work of installation was begun on

Digitized by Google

Monday morning, the 15th inst., at 1 a.m., and the lights were running on Tuesday, the 16th, at 6 p.m., everything having been fixed by that time.

A New Electrical Machine.—The old frictional machines for producing electricity of high tension are now being largely superseded by others of the induction type. One of these, the Voss machine, has of late come into well-merited popularity. The compound plate induction machine of Mr. James Wimshurst also gives excellent effects. This gentleman, however, has now produced another machine which is remarkably simple as well as powerful, says *The Times*. Two circular discs of ordinary window glass 14½in. in diameter are mounted about one-eighth of an inch apart on a fixed horizontal spindle, and rapidly rotated in opposite directions by turning a winch-handle below. Both plates are well varnished, and have 12 radial sector-shaped pieces of thin brass attached at equal intervals on their outer surfaces. The two sectors on the same diameter of each are twice in each revolution momentarily touched by two fine wire brushes at the ends of a curved metallic rod. The fixed conductors consist of two forks in a horizontal position, with collecting combs directed towards each other and towards the two discs which rotate between them. To these combs are attached the terminal electrodes, which have ebonite handles, and may be shifted more or less apart. The apparatus can be made for a few shillings.

Electricity at the Birmingham and Midland Institute.—Our correspondent sends us the following:—"The annual *conversazione* of this institution, extending over four evenings, was illuminated by Swan's incandescent lights, and electricity filled other important parts in the programme. The current was supplied by Messrs. Winfield and Co., from the Cambridge-street works, and the lighting of the Town Hall was precisely the same as on the occasion of the Musical Festival, when we gave a full description of the installation. A lecture was given each evening by Mr. Woodward, of the institute, illustrating the various applications of electricity to domestic uses, as also for lighthouse purposes. The electric light exhibited in great perfection a set of polariscope objects lent by Mr. Spottiswoode, probably the finest set in existence, among them a unique twin crystal of right and left-handed quartz. Of course, these objects were brought out with a brilliancy of colour and a magnitude rarely to be seen. But the illustration which evidently most thoroughly met the general taste was a large fountain fitted up on the platform, and throwing a great body of water nearly to the roof of the lecture theatre. This was illuminated from above through an opening in the ceiling by a powerful arc lamp, producing a succession of varying colours by interposed glasses. The effect was magnificent, especially when two or three stripes of colour were thrown on the moving and changing masses of water; it was not so pleasing upon the faces of the audience when a particular shade of green gave them the appearance of an assembly of the dead. Messrs. Winfield and Co. have succeeded in showing that it is possible to maintain a perfectly steady light hour after hour. The whole of the lights filled the hall with unwavering radiance, and without even a momentary flicker."

Electric Lighting of Workshops.—The French papers of last week give descriptions of a large installation of incandescent and arc lamps that has been carried out at the Railway Waggon Works of Saint Denis. Ten Weston arc lamps and twenty-four Maxim incandescent lamps are employed. The total horse-power available in the workshops is sixty, but of this about fifty is absorbed by the various machines in use, leaving, therefore, only ten for electric lighting purposes. By means of accumulators, however, which are charged during the day by a continuous current Weston dynamo driven with the balance of horse-power available, the difficulty is overcome. The incandescent lamps are fed from the accumulators in the evening, and the dynamo current used during the day for charging the accumulators is available at night for the arc lamps. The accumulators used are those known as the Kabath, with corrugated plates, and 80 of these are employed. It being necessary to shift the incandescent lamps from time to time, as the work in hand may require, the following arrangement has been adopted:—Pairs of naked copper wires are stretched from end to end of the workshops, and connected with the accumulators. On these wires small runners are placed, one on the positive, and the other on the negative wire, and a pair for each lamp; a copper tube, with two horizontal arms at its upper end, these latter being fixed to a pair of runners, suffice to carry the conducting wires to the lamp, which is thus suspended at a convenient distance from the ground. By means of a pole it is easy for a workman to push the whole arrangement any distance he may require along the two copper wires, and transfer the light from one spot to another. Several of these pairs of wires are arranged in parallel lines up and down the workshop at a convenient distance from each other. The whole of the work has been carried out by M. Ch. Farquhar, for M. De Kabath, of Paris.

Birmingham Telegraph Messengers.—A meeting of the messengers employed at the Birmingham Telegraph Office was held last week in the letter-carriers' coffee room of the Post Office. Mr. S. Walliker, the postmaster, presided, and there was a large attendance, the company including the mayor and others. The chairman said the object of the meeting was to encourage the telelegraph messengers in the pursuit of useful knowledge and the profitable employment of their leisure hours. The chief merit in a telegraph messenger consisted in the rapid delivery of messages and in the rapid return of the messenger to the office; and in order that the boys might be encouraged to exert themselves in that respect every minute that was lost was marked down against them; then, at the close of the year, the marks were added up, and the boy that had lost the least amount of time was the boy that stood highest in the merit list. During the past year, a boy named Jeffcott headed the list, he having lost only twenty-four minutes, and he was also the first boy in the previous year's list. The general conduct of the boys was remarkably good. It was very rare now that any were taken before him for misconducting themselves. When he first became postmaster as many as twenty at a time were brought before him, but now it was rare to have three at a time. In order that the boys might have an opportunity of improving their minds he gave them several essays to write on different subjects, and some of the papers were very fairly written. The boys had also sent in some coloured sketches, several of which possessed great merit. Other subjects for essays had also been given, and the prizes for those, as well as for essays already written, and the sketches, would be awarded to successful competitors on the Queen's birthday. Prizes would also be given for proficiency in shorthand, for general good conduct, &c. In the course of the evening the mayor announced his intention of giving three prizes to be competed for by the boys. Mr. S. Walliker is to be congratulated on the good results that have attended his scheme in the past, and we wish him all success for the future. His excellent example might well be imitated in other towns.

THEORY OF MAGNETO AND DYNAMO MACHINES.

XXII.

Summary of last Article.

A given machine has a certain ratio between the resistance of the field magnet wire, b, and that of the armature, a, which is very important, and which we may call the *characteristic ratio* of the machine, and denote by m. One result of the last article was the proof that for high efficiency m must be large, the larger the better.

It will be convenient to write some of the more important expressions of the last article in terms of this characteristic m, or $\frac{b}{a}$.

The "waste ratio" which is given in equation (xiii,), for instance, and which we will now denote by λ, becomes

$$\lambda = \frac{r}{b} + \frac{1}{m}\left(\frac{r}{b} + 2 + \frac{b}{r}\right) \quad . \quad . \quad . \quad . \quad . \quad (xiii)'.$$

N.B.—There is a misprint in equation (xiii.) of last article, p. 78, Dec. 9, an index 2 having dropped from the brackets. The equation should read—

$$\text{waste ratio} = \frac{\text{waste}}{\text{useful}} = \frac{r}{b} + \frac{a}{r}\left(1 + \frac{r}{b}\right)^2 \quad . \quad . \quad . \quad (xiii.).$$

The efficiency f is connected with the waste ratio by the simple equation

$$f = \frac{1}{1 + \lambda}.$$

The most economical value of the external resistance is

$$r = \frac{b}{\sqrt{(1 + m)}}, \quad . \quad . \quad . \quad . \quad (xiv.)'$$

and hence the least possible waste ratio for the given dynamo is

$$\lambda_1 = \frac{2}{m}\left\{1 + \sqrt{(1 + m)}\right\}; \quad . \quad . \quad (xv.)'$$

or, what comes to the same thing, the maximum efficiency is

$$F = 1 - \frac{2}{m}(\sqrt{1 + m} - 1). \quad . \quad . \quad . \quad (xvi.)'$$

Numerical Examples of the Maximum Efficiency of Shunt Dynamos.

As a first example, take a small Siemens D_5 dynamo, with armature resistance $\frac{1}{2}$ an ohm, and field magnet resistance $7\frac{1}{2}$ ohms. Here the characteristic of the machine is 15, which for high efficiency is by no means great enough.

The best value of the external resistance is

$$\frac{7{\cdot}5}{\sqrt{16}} = 2 \text{ ohms nearly.}$$

The least possible waste ratio is

$$\frac{2}{15}(1 + 4) = \frac{2}{3},$$

or the highest possible efficiency

$$= 1 - \frac{2}{15}(4 - 1) = 1 - \frac{2}{5} = \frac{3}{5} = 60 \text{ per cent.}$$

To determine the best arrangement of incandescent lamps: suppose each lamp is a 16-candle Swan, with a resistance of about 28 ohms. If it has only 14 lamps to work, they should be all abreast, in order that their combined resistance may be 2 ohms. This is about what a D_5 machine can thoroughly do.

If the machine could work 56 lamps they ought to be arranged 28 abreast and 2 in series. For intermediate numbers one has to do the best one can, but one cannot hit exactly the most economical value of the external circuit resistance.

Next consider a z machine with the armature resistance $\frac{1}{8}$ ohm, and the field magnet 50 ohms, so that $m = 400$; this is much better.

The best value of the external resistance is $2\frac{1}{2}$ ohms. The least possible waste ratio is $\frac{21}{200} = {\cdot}105$; or the highest efficiency is $\frac{181}{200} = 90{\cdot}5$ per cent.

Suppose this machine had to excite Edison lamps of 70 ohms each: 30 would be best arranged simply abreast; 120 should be 60 abreast, and two in series; 270 should be 90 abreast, and three in series; 480 ought to be 120 abreast, and four in series; and generally the number abreast ought to be 30 times the number in series, in order that the external resistance may be $2\frac{1}{2}$ ohms and the highest efficiency attained.

We may summarise then thus:—For any given machine of which the best external resistance is r, to arrange a given number, N, of similar things, such as incandescent lamps, secondary batteries, or anything of which the external resistance may be said to be R ohms apiece; they should be arranged as nearly as possible so that the number abreast is $\sqrt{\left(\frac{N\,R}{r}\right)}$, and the number in series is $\sqrt{\left(\frac{N\,r}{R}\right)}$.

Examples of Efficiency in other cases.

The efficiency calculated above for the two machines is in each case the best possible, but suppose the external resistance r is not at its most economical value (xiv.), but is, say, $\frac{1}{2}$ ohm., or 10 ohms., what are the efficiencies then?

The small machine with the characteristic 15 will for $r = \frac{1}{2}$ have a waste ratio $\frac{18}{15}$, and accordingly an efficiency of $\frac{15}{33}$, or $45\frac{1}{2}$ per cent.

When $r = 10$, on the other hand, its efficiency will be $38\frac{1}{2}$ per cent.

Showing that it is better to have the external resistance $\frac{1}{8}$th too small than five times too big.

Next try the machine with the characteristic 400. When $r = \frac{1}{2}$ its efficiency is 79 per cent, and when $r = 10$ its efficiency is 82; but if $r = 20$ ohms the efficiency is only 66 per cent.

The general law as to whether, if the most economical value of the external resistance cannot be exactly hit, it is better to make it too small or too big is evident from (xiii.)' and may be thus expressed.

A value of the external resistance, which is a sub-multiple of the most economical value, will give a higher efficiency than if it were the corresponding multiple. But if the external resistance has to differ from the most economical value by a fixed amount, it is better that the difference should be in excess than in defect.

The following curve exhibits the waste ratio of a given shunt machine for every possible value of the external resistance.

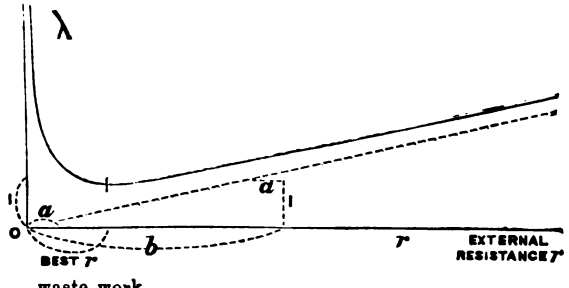
The curve is simply a hyperbola with the two asymptotes, $r = o$, and $\lambda = \frac{a + b}{b^2} \cdot r$.

When r is small it nearly coincides with the hyperbola $r\lambda = a$.

When the external resistance equals the armature resistance, or $r = a$, $\lambda = 1 + \frac{3a}{b} + \frac{a^2}{b^2}$;

when the external resistance equals the field magnet resistance, or $r = b$, $\lambda = 1 + \frac{4a}{b}$;

and when $r = nb$, $\lambda = n + \frac{(n + 1)^2}{n} \cdot \frac{a}{b}$.



Curve of $\frac{\text{waste work}}{\text{useful work}}$ for a given shunt dynamo, for different amounts of resistance in the external circuit. The curve is drawn for the particular values $a = \frac{1}{2}$, $b = 5$. The best r accordingly is 1·5, and here the ordinate of the curve has its minimum value ·863; which corresponds to an efficiency of 53·7 per cent.

CROMPTON'S COMPOUND MACHINE.

BY GISBERT KAPP.

(CONCLUDED FROM PAGE 202.)

In designing a new machine its leading dimensions are determined by the maximum of electrical work it will have to perform. Whether it is to be compounded or not, to satisfactorily do that work the armature must contain a certain number of coils of a given size of wire, and the pole pieces, arms and yokes of the field magnets must be of a certain size and shape, all as experience teaches. The only point left to be determined is the way the field magnets are to be wound. The graphical method for expressing the relation between exciting power and electromotive force, although it does not give rules for determining straightway and at one operation the best dimensions and number of magnet coils, enables us to judge whether a given arrangement be suitable for the particular purpose required. It is therefore necessary to first assume more or less arbitrarily a certain way of winding, and then to investigate by the graphical method the behaviour of the machine thus wound. If the result be unsatisfactory, the diagram will show where the defect lies, and the winding must be altered accordingly, until repeated investigation shows that the best possible arrangement has been found.

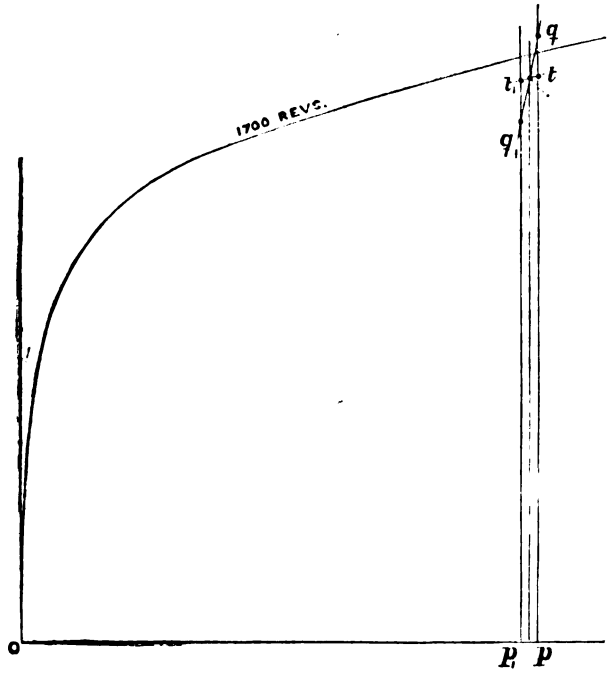

FIG. 7.

The abscissæ in Fig. 7 represent exciting power in ampere turns on one arm of field magnets, a hundred ampere turns being equal to one millimetre. The ordinates represent corresponding electromotive force in armature if no current is allowed to flow through it. One volt equals one millimetre. This curve is not the characteristic curve as usually understood; it corresponds to the dotted line in Fig. 6 (p. 201) with this exception, that in Fig. 6 the abscissæ represent exciting power and external current at the same time, while here they represent only exciting power. It matters nothing whether this is derived from the shunt or the main or from both; the electromotive force is simply a function of the total number of ampere turns.

In Fig. 8 the line O A represents the resistance of armature. For the sake of simplicity it is shown as a straight line, although in reality it is slightly curved downwards, owing to the fact that with an increase of current through the wire its temperature, and, therefore, its resistance, are also slightly increased. The difference is, however, too minute to be shown in a small-scale diagram.

$$R = \text{tan. A O X.}$$

To drive a current O e through the armature, an electromotive force equal to ea is necessary. Introducing our former symbols, we have

$$E a - E b = e a.$$

Similarly, O L represents the resistance of main exciting coils and line, $c k$ being the electromotive force necessary to drive the current O c through it.

$$E b - E l = c k.$$

The resistance of shunt coils is represented by the line O s.

$$\rho = \text{cotan. Y O } s.$$

If the electromotive force at the brushes be O f the current it will drive through the shunt is represented by the length $f g$, the scale of the diagram being, as before, 1 volt and 1 ampere equal one millimetre. The exciting power of main

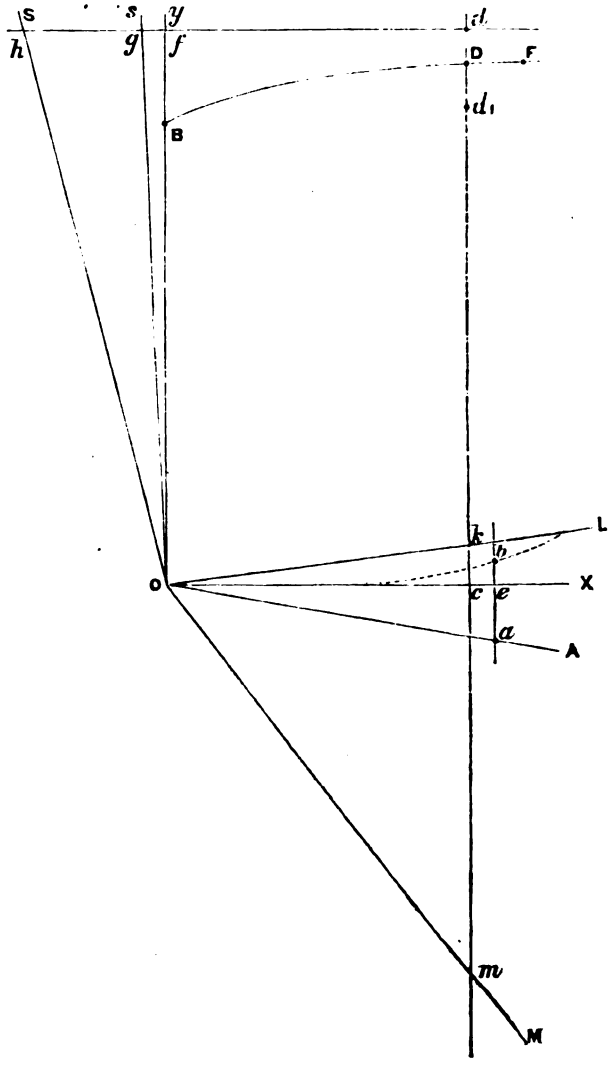

FIG. 8.

coils being proportional to the product of number of turns and external current, the ordinates of the straight line O M will give main-ampere-turns if the tangent of angle M O X be equal to the number of coils employed, the same scale as in Fig. 7 being, of course, used. In the same way the shunt-ampere-turns can be represented by the straight line O S, the tangent of angle S O Y being equal to number of shunt coils divided by the resistance of shunt

$$\text{tan. S O Y} = \frac{v}{\rho}.$$

From this equation it will at once be seen that the exciting power of the shunt cannot be increased by piling more wire on to it, for in the same ratio as the turns are multiplied the resistance is also increased, and hence the quotient $\frac{v}{\rho}$ remains unchanged. This holds good within certain limits,

but if too much shunt wire is used its efficiency will actually be reduced, for not only do the outer coils on account of their greater length offer more resistance than corresponds to their number, but being farther removed from the magnet core, their magnetising power is also at the same time lessened. On the other hand, a large number of shunt coils tends to economise current.

The dotted line in Fig. 8 represents the difference of electromotive force in the armature with a current passing and without it, as explained in the last article (see Fig. 6 on page 201). If a current O e be permitted to flow through the armature its electromotive force will, other things being equal, suffer a reduction $e\,b$ as compared to the electromotive force if no current passes. The curve representing this reduction must be found experimentally in the manner explained in the last article.

Our problem now stands thus:—Given an external current O c, we desire to know what electromotive force between lamp terminals it will have. The first step towards solution of this problem must be a guess at the external electromotive force; say we assume it to be $k\,d$. By drawing a horizontal through d (or, in the case of the shunt current being also carried through the main coils, a straight line under an inclination, the tangent of which is equal to the resistance of main coils) we find point f, the distance of which from o represents the electromotive force creating the shunt current $f\,g$. This added to $O\,c$ gives $O\,e$, the total current through armature.

The total exciting power is $c\,m + f\,h$ ampere-turns, which sum in Fig. 7 is represented by the length O p. To obtain an external electromotive force, $k\,d$, the total electromotive force in armature must necessarily be

$$c\,d + e\,a = p\,q.$$

This, however, does not satisfy the condition represented by the curve in Fig. 7. It will be seen that the electromotive force which actually exists in the armature is $p\,t$, this being the ordinate of the curve minus loss $e\,b$. Our first guess has, therefore, been too high. By assuming a lower value, say $k\,d_1$, and, repeating the process, we find the points p_1, q_1, t_1. This time the guess was too low, the real value being between the two. It is in Fig. 7 the point of intersection between the two lines $q\,q_1$ and $t\,t_1$, and in Fig. 8 the point D, which divides $d\,d_1$ in the same geometrical proportion as T divides $q\,q_1$. The electromotive force between lamp-terminals is, therefore, represented by the length k D. It need hardly be mentioned that the accuracy of the result will be the greater the nearer the points $d\,d_1$ are to the real value.

In similar manner E l can be found for other external currents, and thus the curve B D F can be plotted. Absolutely perfect regulation would be obtained if B D F were not a curve, but a straight line parallel to O L. Considering the complicated nature of action and reaction which influence the shape of this curve it is very doubtful whether such absolutely mathematical perfection can be obtained. But, for practical purposes, it will suffice if the curve is very flat, and if its position is nearly coincident with the above-mentioned straight line. Should it be found that deviations exist too great for the safe and steady working of the lamps, it is a sign that the manner of winding was not well chosen. It must be altered until repeated investigation shows a satisfactory result.

ELECTRIC LIGHTING AND BALLET-GIRLS.—The ballet at the Princess's Theatre, Manchester, in which twenty-six ladies take part, has for the past month been danced nightly by the light of small Swan lamps, placed in a flower on each lady's head. The current is supplied by a small battery, the weight of which is about 1½lb., carried on the back of the dancer, as at the Savoy Theatre. None of the ladies are at all frightened, in fact they like it so much that the principal dancer, Miss A. Holt, has arranged to have her dress covered with the lamps, which will be done ere this is in print. The arrangements have been carried out by Mr. H. Bury, of 46, Market-street, Manchester.

THE INDUCTIVE AND CONDUCTIVE CIRCUITS.

II.

BY JOHN T. SPRAGUE.

The two circuits always co-exist, but it is evident that the inductive process precedes the actual conduction, and the step by step induction is, so to speak, the tentative process by which true conductive path, that is to say, the constitution of the true electric conditions, or circuit, is developed. Here the two conceptions of the nature of electricity diverge. All the known facts of electricity show that it is a dual action. All the theories—the two fluid, the single fluid + and —, or the molecular theory, which considers the two electricities, or rather electrifications, as merely the two sides or ends of polarised matter—agree in this. But the mathematical treatment is based upon single and independent actions, and some experimenters have sought to prove the existence of *unipolar actions* such as accord with this treatment. In Fig. 1 we have the picture of such supposed actions. The independent pole +, acting as a radiant point, *induces* polar order in all surrounding matter. In such an action it is clear that each circle will be an *equi-potential line*, with no tendency to side actions, that is, not from any reality in the potential conception, but simply because the force is radial only, and every particle of matter takes up what force its position presents to it. Also every such circle will have equal force acting from it, also radially, and, therefore, the force at each point of each circle will be inversely as the square of its distance from the centre. That is to say, the tension on each molecule in the lines of the field of force thus generated will diminish as the square of its distance.

FIG. 1.

Now, we have a perfect physical analogue of this. Let a smooth plane surface receive a supply of water at its centre, and it will flow outwards in all directions in this exact manner, and its distribution upon and velocity of flow will be identical with the conditions of Fig. 1, in which I have endeavoured to represent the facts by the diminished size and increasing number of molecules as the distance increases.

If we now conceive of some condition which puts this plane surface out of level, the flow of water will at once be altered into an elliptic system, narrowing the more as the inclination increases. If we conceive the plane as perfectly balanced on its centre, any cause which induces the water to tend, however slightly, rather in one direction, will at once cause the plane to cant over, and direct the line of flow more and more in this direction.

Just such an influence we have in electricity. *The second radial system — is always somewhere;* it may be conceived as a second system similar to Fig. 1, but with the direction of the arrows representing the lines of force towards instead of from the centre. Therefore the circles of these two fields must ultimately meet, and when they do the lines of force attract each other with an effect similar to that of tilting the water plane, that is they convert the two supposed independent radial points into the foci of an ellipse, and the imaginary radial lines into the curved lines of a closed field of force. I have endeavoured to show this action in Fig. 2. It is evident here that as soon as the circles of influence cut each other the molecules are subjected to the influence of both foci, generating tension in the same direction. Now, pictorial representation cannot convey directly the well-known fact that the electric force exerts itself in the direction of *most capacity*, and this, as well as the law of inverse squares

Digitized by Google

will, therefore, concentrate the action into the space enclosed by the arrows.

This process of induction occurs in the lines of most capacity, or reciprocally of least resistance, and, therefore, if there be a good conductor in the line, that becomes the shortest path, and is represented by the thick line between + and —. Along this line the constant charge and discharge, or molecular interactions, which we call *current*, are propagated. But the external induction is maintained as a condition of static stress or tension, and constitutes the inductive circuit around the conductor, taking a static charge corresponding to the forces exerted at each point, and the capacity of the medium. But, if there is nothing to represent what is ordinarily called a conductor, still there is current; every substance whatever has some conducting capacity, and, therefore, there must needs be a constant transmission of electric current along the lines of force of the inductive circuit—a fact which, while ignored in theory, is practically known to every one who makes an experiment and finds his electric charges gradually weakening.

The direction of the arrows in diagrams of this sort is not merely an aid to the imagination, it represents a physical fact; for, though the forces of the two poles, + and —, are equal, as also the so-called quantity at each, yet there is some real difference in their mode of action. In the discharge it is always found that there are lines of spreading action at the + pole and of concentrating action at the — pole. The brush forms at the + pole, and even when the whole discharge fills an elliptic field it is broadest at the + end, although in vacuum tubes there is commonly a glowing appearance around the negative electrode, which in the highly exhausted tubes of Mr. Crookes is seen to pass into a dark interval.

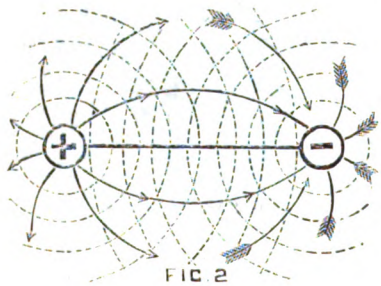

FIG. 2

While on this subject it may be desirable to refer to one of the best evidences ever presented of the independent polar action, or *unipolar discharge*. It is contained in a very interesting paper by Messrs. Spottiswoode and Moulton (*Phil. Trans.*, 1879, p. 165). They connected one end of two vacuum tubes (constituting derived circuits) to the — pole of the coil, and the other ends to a ball fixed at a small distance from the + pole, so that the current was more interrupted and shorter in duration (as due to a spark) than if coming direct from the wire in a closed circuit. The spark selected one tube rather than the other for its proper path, and in the other tube it only produced a glow extending half way along it in a reducing cone. Of this tube they said that the discharge in it is, in fact, one which leaves the + pole and enters the tube, but not with sufficient force to pass through it, and which returns on itself. But the real explanation is most simple, and accordant with the universal facts of electricity. The tubes are not quite equal in resistance, or some accidental circumstance in or around them transforms the partial discharge through one tube into a circuit through and along the glass of the tube itself. The authors took the trouble to prove this without seeing it, for they made a tube with an intermediary electrode connected to one of the end terminals and to the + pole, the other end going to — pole. The circuit might be expected, in this case, to confine itself to the latter half of the tube, but actually two cones formed in the other half, representing opposed unipolar discharges. These are evidently a double derived circuit closed on the glass of the tube. This, also, the authors proved without seeing it. Returning to the two-tube experiment, they attached an external conductor to the + pole, and approaching it to the exterior of the tube just beyond the supposed unipolar cone discharge they drove it back and stopped it. Obviously, they added an external counter force which, preventing the completion of the circuit, prevented also the discharge. The case is precisely like getting a shock from one terminal of a coil, the circuit completing itself through the partially conducting supports, or the current passing into my galvanometer from the one pole of the Voss machine, as described by me in *The Electrician* for January 20th, 1883, page 222. The conclusion of the authors, that each terminal pours forth its electricity to satisfy its own needs, and only in a secondary degree to satisfy the needs of the other terminal, must be exchanged for this other conclusion, according with all the facts of electricity, that as electricity divides among all the paths open to it, each terminal finds its circuit to the other, either directly or indirectly, by conductive or by inductive processes, but that *each takes equal part in every act of discharge*, and cannot generate electrical discharge until it has found a circuit uniting it to the other.

CORRESPONDENCE.

THE FLAME ELECTRIC TEST AND THE VOSS MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am gratified by Mr. Sprague having made known through your columns the result of his having tested my discovery that an insulated flame indicates the direction of a current of electricity when it is passing through air. He writes, page 222 of your present volume:—"I took the opportunity of testing the action on flame, as to which Mr. Johnstone wrote so strongly some time since, with results, as I expected, very different from his." Now, from what follows of Mr. Sprague's own statement of his results, it is manifest that they are identically the same as mine, as long as Mr. Sprague followed the line of experimenting which I published in your columns, but his remarks also show that when he proceeded to a new line of experimenting of his own then he got different results.

1st. He writes that "he used a benzoline sponge lamp, made of metal, and stood between the balls (of the Voss machine)." Mr. Sprague adds:—"Of course the flame tended towards the — ball, as though blown over from the + (ball), while the lamp was insulated." Now this is an admission that he found the truth of my discovery of 1839, that an insulated flame indicates the direction in which a current of electricity is passing through air.

2nd. Mr. Sprague then proceeds to institute a new set of experiments. After having deprived the lamp of its insulation, he writes:—"But, if a connection was made to it (the metal lamp) from either pole, the flame was attracted to the other pole, provided the machine were worked gently." There is no wonder that Mr. Sprague got these results, and that they are different from my results, because he worked with a flame which was not insulated, and was supported by a metallic stem. But there is something more than this to be taken into account. Mr. Sprague admits that he is acquainted with that which I long ago found to be a very serious defect in the Voss machine, namely, as he writes, "a tendency to self-reversal," that is to say, when experimenting with a Voss machine, and the current of electricity is passing from the right-hand ball to the left-hand ball, in a moment, with the swiftness of a flash of lightning, the machine, by its own spontaneous action, changes the direction of the current of electricity, so that it goes from the left-hand ball to the right-hand ball. When charging a Leyden jar at a Voss machine, sometimes the action is as follows:—Having placed the ball of the Leyden jar near the ball of the Voss machine, which, for the time being, was giving out the current of electricity, the jar would begin to be charged with electricity, but all of a sudden, without any warning, the direction of the current in the machine would be changed, and, to the experimenter's

Digitized by Google

surprise, he would find that instead of electricity going into the jar, it was being sucked out* of it.

From these facts it is manifest that the Voss machine cannot be trusted to make with it delicate experiments such as Mr. Sprague has been performing with an uninsulated flame on a metallic stem.—Yours, &c.,

JAMES JOHNSTONE.

Experiment Rooms, 1, James-square, Edinburgh.

THE ACTION OF MICROPHONES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I deem it unnecessary to say more on this subject beyond pointing out that Mr. Smillie in his first letter distinctly and repeatedly attributed microphonic action to compression of the carbon; and in his second (having in the interim read Mr. Rathbone's reply and mine) he omits all mention of compression, and talks in a vague way of contacts open (*sic*) and intermittent. I say vague way, because, with the best of intentions, and considerable practical knowledge of the subject to guide me, I have failed utterly to make out what he means. It suffices, however, that he abandons the compression theory. That is what I objected to. If Mr. Smillie writes again, his letter, I think, should take the form of an apology to Professor Blyth. I see that Mr. Smillie in his second letter makes out that I alleged that a brass button would speak as well as a carbon one. Of course I said nothing of the kind. I suggested an experiment with a metallic button—which would, of course, be practically incompressible—for the purpose of showing that microphonic action is due to the contacts between the surfaces, and not to actual compression of the buttons. Mr. Smillie made a brass button speak, which proves my case to the hilt. He says that he did not get the galvanometric action I predicted. If not, his instrument must be a poor one. With a reflecting galvanometer, the spot would have gone off the scale in response to the tickling. Mr. Smillie asks me to give my name. I decline to do so, not being in need of a cheap advertisement.—Yours, &c.,

London, January 22, 1883. LOOSE CONTACT.

RESISTANCE OF ALLOYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In his inaugural address as President of the Society of Telegraph Engineers and of Electricians, on the 18th inst., Mr. Willoughby Smith drew attention to the fact that the resistance of a wire composed of an alloy of, say, two metals was always higher than the combined resistance of the metals when separate.

This, I believe, is only true in cases of real *chemical* combination, Professor Matthiesen having long ago shown that whenever the combination was simply a *mechanical* mixture the resistance was the same. No explanation of these different behaviours of chemical and mechanical alloys, or mixtures, has ever, so far as I know, been offered, and it is with some diffidence that I now venture to give expression to views which I have long held on the subject.

Suppose a magnetic needle surrounded by a coil composed of two (different) metallic wires twisted together—a mechanical mixture. An electric current, in flowing round this coil, does work (magnetic work) in deflecting the needle, and this deflection we take as a measure of the conductivity, and, therefore, of the resistance of the wire. In the case, however, of the same wires chemically mixed, we have a compound body—a metallic electrolyte, in fact—in flowing through which the electric current does other work besides deflecting the needle. It reduces, or tries to reduce, the alloy into its constituent parts. By the amount of force so expended the magnetic effect of the current is reduced, the conductivity appears to be less, or, in other words, the resistance appears to be greater. But where is the evidence of the chemical work of decomposition here mentioned? May it not be found in the fact that wires which have long conveyed electric currents become brittle, disintegrate? This has been observed in the earlier cables, for instance in the Calais-Dover cable of 1851, and in the wires of old relays, as in the Persian Gulf.

I will ask you to publish this letter in the hope that it may elicit the views of some of your readers on a most interesting subject, as well as one of great practical importance to the electrician, I mean the electrical permanency of metals.

If my views be correct a chemically pure wire will never become brittle, a point which the powerful currents now used in electric lighting will soon enable us to determine.—Yours, &c., J. J. FAHIE.

* I have used the words "sucked out" because I maintain that the experiments I previously published in your columns prove that electricity is a peculiar kind of matter.

AUSTRALIAN TELEGRAPH ALPHABET.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will any one inform me what telegraph alphabet is used on the Government wires in New South Wales? I believe it is not the same as our English alphabet as at present in use in the Post Office, and I should be very much obliged if any of your correspondents can supply me with a a copy of it. H. M.

STUDENTS' COLUMNS.

CITY AND GUILDS EXAMINATIONS.

[*These answers are intended to guide, to give information and references, to put the student in the way of getting information, and* NOT *to give the exact answers that should be written in an examination.*]

The solutions in this number are alternative solutions to some of the "*Honours*" questions in the paper hitherto considered, by E. C. RIMINGTON, ESQ. (School of Electrical Engineering), 12, Princes-street, Regent-street.

9. Describe the construction and action of various forms of speed counters for use with dynamos.

Ans. Speed counters may be divided into two classes, viz., those which require to be kept on the dynamo for an accurately-timed minute or half minute, and those which give the speed by simple observation. Of the former class, Harding's patent speed-meter may be taken as an example. It consists of four discs, each divided on the edge into 10 parts, numbered from 0 to 9, so arranged that when the axle, which is attached to the dynamo, makes one revolution it moved the unit wheel $\frac{1}{10}$ of a revolution, and when the unit wheel makes one revolution it moves the tens wheel $\frac{1}{10}$ of a revolution, and so on.

Of the second class, Young's patent speed indicator may be taken as an example, a description of which will be found in No. 15 of the last volume of *The Electrician*. The indications are, in this case, effected by means of a small high-speed centrifugal governor, which acts on an index or pointer.

10. You are required to ascertain the efficiency of a dynamo. Describe in detail the experiments you would carry out for this purpose.

Ans. The efficiency of a dynamo is expressed by the ratio of useful work, or electrical work done in the external circuit to total work or work done upon the machine. To obtain the efficiency of an ordinary dynamo machine, run it through the external resistance for which it was designed, taking the current and E.M.F. at the terminals of the machine, also take the work put into the dynamo by means of a dynamometer such as the transmission power dynamometer.

The total E.M.F. of the machine is obtained by multiplying the E.M.F. at the terminals by the total resistance in circuit, and dividing the result by the external resistance. The power expended in the external circuit $= \frac{E_1 C}{746}$ h.-p. where E_1 = E.M.F. at the terminals of the machine. The total electrical power expended $= \frac{E C}{746}$ h.-p. where E = total E.M.F.

Therefore, the power expended in the coils of the dynamo $= \frac{(E - E_1) C}{546}$ h.-p.

If P be the number of h.-p. registered by the dynamometer, $\frac{E_1 C}{746 P}$ is the efficiency of the dynamo.

$P - \frac{E C}{746}$ being the h.-p. required to overcome the frictin of

Digitized by Google

the bearings and the friction and resistance of the air to the revolving armature.

If we do not consider the mechanical waste of power in heating the bearings, &c., the electrical efficiency

$$= \frac{E_1 C}{E C} = \frac{E_1}{E}$$

If R = the total resistance in circuit and r = the external resistance

$$E_1 = r C \quad E = R C,$$

therefore the electrical efficiency $= \frac{r}{R}$.

The electrical efficiency of the shunt dynamo, leaving out of consideration the mechanical waste of power, is rather more complicated than the above.

Let a = resistance of the armature in ohms.
" b = " " field magnets in ohms.
" c = " " external circuit in ohms.
" A = current through armature in amperes.
" B = " " field magnets in amperes.
" C = " " external circuit in amperes.
" e = *er* E.M.F. at the terminals of the machine in volts.

Then

$$e = B b = C c,$$

$$\therefore B = \frac{C c}{b},$$

$$A = B + C.$$

Now work in external circuit $= c C^2$, and total electrical work done equals the product of the total resistance and the square of the total current

$$= A^2 \left(a + \frac{b c}{b + c} \right)$$

$$\text{efficiency} = \frac{c C^2}{A^2 \left(a + \frac{b c}{b + c} \right)}$$

$$\text{but } A^2 = (B + C)^2 \text{ and } B = \frac{c C}{b}$$

$$\therefore \text{efficiency} = \frac{c C^2}{\left(\frac{c C}{b} + C \right)^2 \left\{ \frac{a (b + c) + b c}{b + c} \right\}}$$

$$= \frac{c}{\frac{(b + c)^2}{b^2} \left\{ \frac{a (b + c) + b c}{(b + c)} \right\}}$$

$$= \frac{b^2 c}{a (b + c)^2 + b^2 c + b c^2}.$$

In actual practice we should, as in the case of an ordinary dynamo, have the efficiency $= \frac{e C}{746 P}$ where P is the number of h.-p. indicated in the dynamometer attached to the machine.

CHELSEA ELECTRIC LIGHTING.

The Electric Lighting Committee of the Chelsea Vestry has adopted the following observations upon the Draft Provisional Orders in the Board of Trade, 1883:—"In accordance with the request of the Electric Lighting Committee, we have given full consideration to the provisions contained in the Draft Provisional Order of the Metropolitan (Brush) Electric Light and Power Company (Limited), who are seeking power to supply electricity to Chelsea. In the first instance we think it right to state that we do not regard with favour the scheme as it now stands, because it is prepared upon an unsound basis, many of the clauses in the draft being objectionable and otherwise unfair to consumers. The chief objection to the scheme, however, is that the company are asking for powers to create a 'permissive monopoly' in a manner contrary to the spirit of 'The Electric Lighting Act,' and altogether in our opinion not for the public benefit. Although the company have scheduled the entire parish as the 'proposed area of supply,' they only seek to expend capital to the amount of £14,040. Such a sum would be ridiculously inadequate for so extensive an area. The provisions with regard to:—(*a*) conditions of supply; (*b*) affording relief from compulsion to lay mains in such streets as the company may think fit; (*c*) omitting such streets from the area of supply (but not otherwise relinquishing the company's right over the same); (*d*) the various delays which would occur before the company could be declared to have made default; (*e*) the relief of the company from penalties for neglect and failure to supply; (*f*) the mode of procedure in respect to laying electric mains; (*g*) the breaking up of streets; (*h*) the sub-division of the area of supply; (*i*) the power to make the supply intermittent; (*j*) the cost of service lines under the streets; (*k*) the price and mode of measurement; (*l*) the penalties for default; (*m*) partial revocation of the order; (*n*) the transfer of the undertaking, and (*o*) the duration of the order, are such as in our opinion would render it desirable in the interests of the ratepayers to entirely reject the scheme rather than to submit to the onerous conditions which the company seek to impose. It certainly appears prejudicial to the ratepayers that such a 'permissive' right should be granted for so insignificant an expenditure as £14,040, especially as the provisions for the sale and transfer of the undertaking are so framed that a speculating company might thus cheaply acquire a right to the entire district, and, as electric lighting advances, resell such right (or from time to time any portion thereof) to other persons, a procedure which should be guarded against by strenuous opposition. Under the proposed system of relief from compulsory supply the inhabitants of the more unimportant streets may for ever be prevented from obtaining the benefits of electricity, it being obvious that if the Company were to supply the principal streets only, it would not answer the purpose of another company to take the smaller streets alone, by reason of their isolation, irregularity of consumption, and the cost of supply. With a view to facilitate the introduction of electricity into Chelsea upon a satisfactory basis, at as early a date as possible, and in preference to offering the existing scheme an uncompromising opposition, an amended scheme has been propounded by your surveyor, and his plan forms the foundation of the necessary amendments which the Board of Trade should be asked to include in the draft order. The amended scheme proposes that the Company should forthwith select one of the three areas (or a modification thereof) suggested by your surveyor upon the map herewith submitted; that the obligation to supply the area so prescribed be compulsory, but progressive in the manner specified in the schedules; that the draft order be amended accordingly (the list of streets referred to in the schedules being next filled in as may be agreed upon); and that the remainder of the amendments in the draft, which have been made in red ink, together with the additional clauses, be likewise insisted upon as far as possible. We have conferred with your solicitors (Messrs. Lee and Pembertons), who have, under our instructions, prepared the annexed draft letter to the Board of Trade, together with numerous red ink amendments in the draft order, which we recommend be sent to the Board of Trade, and to Messrs. Walter Webb and Co., the solicitors to the undertakers, not later than the 1st day of February next. The draft orders of the Swan United Electric Light Company, which affect this parish, have also received our attention, and draft letters (prepared by the solicitors) are herewith submitted, which we recommend be sent to the Board of Trade and to the undertakers' solicitors. We also submit a letter from the Board of Trade respecting the capital proposed to be expended.

"CHARLES MOSSOP, Chairman of the Electric Lighting Committee.

"GEO. H. STAYTON, Surveyor to the Vestry."

The suggested letter to be addressed to the Secretary of the Board of Trade states that the capital to be expended, viz, £14,040, is inadequate for the area covered by draft provisional order, and the area should be restricted. It criticises the proposed conditions of supply, and suggests other conditions. Paragraphs also refer, among other things, to the position of mains and stations, to the breaking up of streets, to the intermittent supply, to the cost of service lines, to the price to be charged, to measurement, penalties, removal of mains, provisions for safety, and so on. The most interesting paragraphs are as under:—

"AS TO CONDITIONS OF SUPPLY.—(*a*). For private purposes: The vestry propose that within two years the undertakers shall lay distributing mains and supply electricity along the principal streets of the area chosen, as specified in Shedule A to the order; that they shall in the next year similarly take in hand the streets specified in Schedule B, and that, with regard to the remaining streets, to be described in Schedule C, they shall only be bound to furnish a supply after three years if required by one-third of the occupiers in any street, and within one year after requirement. (*b*). For public purposes: The vestry propose that the undertakers shall not be bound to supply electricity for public purposes unless the vestry shall require them so to do; but that if required the undertakers shall within two years supply the streets specified in Schedule A; within another year the streets specified in Schedule B; and, at any subsequent period, the streets described in Schedule C within six months after requirement.

"AS TO POSITION OF MAINS AND STATIONS.—(*a*.) That before commencing the works the undertakers should submit descriptive plans for their approval, and that, in case of difference, such plans should be settled by the Board of Trade. (*b*.) That, wherever practicable, a distributing main should be laid under the footway on each side of the street, so as to avoid the interruption of traffic and breaking up of roads which would be occasioned if the lines were laid under the roadway. (*c*.) That the

Digitized by Google

sites of the electric stations should be approved by them, the undertakers having a right of appeal, in case of difference, to the Board of Trade.

"As to Intermittent Supply.—The vestry object to permission being granted to the undertakers to cease the supply of electricity altogether for two hours per diem. They submit that the undertakers must accept the responsibility of providing a constant supply, as the inconvenience occasioned to consumers may otherwise be very great.

"As to Price.—The draft order contains only general provisions in regard to the price to be charged by the undertakers. The vestry submit that a maximum price should be fixed by the Board of Trade for the supply of electricity both for public and private purposes; and that, as electricity is at present experimental, the prices charged should be revised by the Board of Trade every five years. The vestry also submit that they should be heard on such revisions, and be empowered to appoint some qualified person to examine the company's accounts."

THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

PRESIDENTIAL ADDRESS.

At the meeting of this society, on Thursday, the 18th inst., the newly-elected president, Mr. Willoughby Smith, was installed by the retiring president, Colonel C. E. Webber, R.E. A hearty vote of thanks to the latter, and a message of condolence to the family of the late ex-president, Mr. C. V. Walker, F.R.S., on the loss they had sustained by his death, having been agreed to, Mr. Willoughby Smith then read his inaugural address. After referring to the youth of the society and the great progress it had made during the short period of its existence—a circumstance which was to be ascribed not to any long line of illustrious names which some ancient societies could boast of, but to the rapid growth of electrical science, and extension of its application to practical affairs which had taken place during the past ten or eleven years—Mr. Smith went on to show that every branch of science has progressed in proportion to the accuracy and delicacy of the appliances with which they have to work. And this was true of no branch of science more than of that in which telegraph engineers and electricians were interested. Besides apparatus, however, there was also needed an exact system of measurements upon which uniform and coherent calculations could be made. Some advances had been made in these latter respects by the adoption of electrical units; but a good deal still remained to be done, and it was to be hoped that the Paris Electrical Congress, which had adjourned till the end of the present year, would by that time be in a position to unanimously agree upon standards which would be at once practical, international, and reliable. To the practical electrician—and Mr. Smith confined himself throughout to practical matters—the material was the important thing, not the definition or the nomenclature. For example, it was possible to buy copper wire of higher standard than the one authoritatively recognised, the characteristics of so-called pure copper wire differing greatly with the place of its manufacture. This was shown by the results of tests of five samples of pure copper of same length, gauge, and temperature, which showed that their specific conductivity was a long way from being uniform. Mr. Smith then dealt with the subject of dielectrics with which he had had a great deal to do in connection with submarine cables. Here, again, the change or original difference of material rendered mere definition of hardly any use. Difference in age and temperature completely alters the characteristics of the insulator. Resistance of the gutta percha, for example, increases with age, as shown by a table of tests taken over a succession of years, the increase in some instances being nearly threefold. Again, it was more and more evident that a constant electromotive force should be at our disposal for electrical measurements. Much, no doubt, had been done in this direction, but it was still a fact that no battery had yet been devised whose constancy could be maintained and depended upon for any length of time.

Amongst the many discoveries that had remained idle and unserviceable for years, Mr. Smith supposed he must include that of the peculiar properties of selenium with which his own name was associated. At one moment expectations had been raised as to its utility in connection with the photophone; but he had been sceptical about this from the first, and events had shown that the effects were not due to the use of selenium, but were common to other substances, and attributable to radiant heat rather than to light. Nevertheless, he was sure that some work was to be got out of this metal, for where light was absorbed, as was the case with selenium, work was capable of being performed by it. In connection with this matter some experiments he had made with various kinds of light, from an ordinary candle to that of an electric light, were of interest. A selenium cell being placed in circuit with a galvanometer, it was found that the rise and fall consequent upon the change of light, although very marked, were not completed all at once, the rise being followed by a slowly succeeding and further deflection, the fall by a gradual further decline. This showed that the absorption and giving out were not instantaneous, but occupied an appreciable time.

Turning to the subject of earth currents and similar phenomena, Mr. Smith observed that so soon as "earth" was used for the return current, as it was then called, on telegraph lines, magnetic disturbances were observed, and gave much trouble. To the present day we had not by any means eliminated this disturbing element. But some useful results might follow therefrom if it induced us to establish points of observation, as had been done in respect to terrestrial magnetism; to take note of and collect statistics as to earth currents, their strength, their direction and duration. If we could, so to speak, link the aurora to terrestrial magnetism, and this again to earth currents, how much more easily might we then be able to link together many other natural phenomena in one and the same chain!

After sketching the adaptation of the magnet to various electrical uses Mr. Smith pointed out that we were now engaged in obtaining powerful magnetic fields, especially for electric lighting purposes, but that we had not yet arrived at certainty as to the quality of the iron to be employed or the best way of applying the wire. Illustrating this latter point diagrammatically, the best position could be shown by sliding a secondary coil, to which a galvanometer was connected, along a primary coil in the form of a bar electro-magnet. The deflections would thus be shown to be greatest when the lines of force cut the secondary coil at right angles. As regards the metal employed, his experiments, which had already been published, were here illustrated. Two flat spirals facing each other some distance apart, and connected with reversers, were separated by the metal plate to be tried. The results were very curious, and depended not entirely upon the character of the metal, but upon the speed of the reversals. Copper was unable to intercept the inductive effects between the two spirals when the reversals were slow; whilst iron was uniform, or almost uniform, irrespective of speed. The same was true of lead; but zinc and tin varied the induction with every variation in the speed of reversals.

Some defects in our present system of protecting buildings from the effects of lightning were dealt with next, and the hope expressed that, as the use of electric light and power became general, the care of lightning conductors would fall into the hands of more competent men. With regard to electric lighting, the chief defects noticeable at present were the frailty and impurity of carbons, and the insecurity of insulation. As to the former, their manufacture goes on steadily improving, and, in regard to the latter, experience was teaching its useful lessons every day. Metals, it was suspected, fuse most easily when a current is passing through them, and, as the temperature alters the resistance, the insulator is subject to an increasing liability to destruction the longer the current remains on. The unprecedented demand upon the resources of electrical engineering had for a time caused inexperience to step in where experience feared to tread; but this danger is now rapidly disappearing. One other drawback felt at present is the want of a good system of photometric measurements, the eye not being trustworthy for so delicate an operation.

The storage of electricity was, of course, a great *desideratum*, and, backed by the name of one who stood very high in the profession, a secondary battery of extraordinary pretensions had raised expectation to the highest. But two years have passed away without any useful result following the importation from Paris of that marvellous box, and in the interval experiments had not proved favourable to this class of battery. The difficulties of storage, though probably not insurmountable, have yet to be overcome. When submarine cables were first projected all sorts of imaginary difficulties and dangers were conjured up against them, but they have triumphed over all obstacles, and he, Mr. Smith, believed that in like manner electric lighting enterprise will achieve a great success. After some brief references to the Postal Telegraphs, the telephone, and the microphone, Mr. Smith concluded with an earnest appeal to students of electricity, both theoretical and applied, not to be in a hurry to make a market of their talents, never to be ashamed to confess ignorance, always ready to listen to those who can teach; and, as to the rest, learn above all things to "labour and to wait" for that reward which, sooner or later, comes to every honest and patient worker.

A vote of thanks, and a request that the address be printed in the society's *Journal*, having been proposed by Professor Adams, and seconded by Mr. Spagnoletti, it was carried unanimously.

THEORY AND PRACTICE.

The extremely interesting and eminently practical address delivered before the Society of Telegraph Engineers and of Electricians last week by its newly elected president may be said to be a sort of supplement to another presidential address delivered last August. Comparison is unavoidable; and although comparisons are things to be generally avoided, in this case happily they can be instituted without being odious to anybody. Indeed, the two addresses to which we are referring may be taken, as a whole, with much profit, and as mutually balancing each other. We pointed out at the time some of the defects of Dr. Siemens's scheme of scientific development, and we think that those defects are, to a great extent, now made up by that of Mr. Willoughby Smith.

Differing as do these two representative men on the debatable ground of ways and means, they resemble each other apparently in their zeal for the practical side of scientific investigation. Possibly as individuals their training and career may have been very unlike; but they are both practical electricians who in part adopt and apply the scientific researches of others to practical purposes, and in part depend upon their own independent study. Yet no one who heard their careful and deliberate utterances in regard to these matters could fail to notice that their respective standpoints were not exactly the same. Both were anxious that practice should go hand-in-hand with theory, and that neither should disdain the companionship. But it was plain Dr. Siemens thought that science should take the lead, whilst it is equally plain that Mr. Willoughby Smith troubles himself not the least about who should lead, but is content to affirm that practice does lead. Of course, the lead in this connection means the lead in practical application, and, no doubt, the statement in that sense is correct. Dr. Siemens wished to readjust matters by holding out a strong inducement on the one hand to the scientist to become more practical, and on the other to the practitioner to become more scientific. We ventured to suggest that if the scientist entered on a career of the kind recommended, a career repugnant to all the oldest and most cherished traditions of the scientific school, he would run the risk not only of losing caste but of wasting time. We were not alone in taking this view, and on the whole it may be predicted as certain that, except under the temporary temptation of a money-making mania, the scientist will follow on the old lines in spite of all invitations to depart from them.

The appeal of the new president of the Society of Telegraph Engineers and of Electricians—what a pity this society itself does not take practical advice and shorten its title!—is of quite another complexion. Dr. Siemens had proffered his encouragement and advice to the scientist, and had reserved all his scoldings for the working practitioner. Mr. Smith almost reverses the operation, giving, at all events, the scientist to understand that he does not quite come up to Mr. Smith's ideal—certainly not up to his requirements. His paper, in fact, was the statement of a long list of deficiencies which science had not yet been able to supply, and for which the working practitioner was still waiting. If the scientific school took it into its head to get rich in haste, there would be little speed made in satisfying the wants of practical men. What these wants were Mr. Smith indicated categorically, and with an unmistakable moral. There remains still a great deal that science has yet to discover, to explain, and to render accessible to practical minds; and, in short, if science would stick to its own business as exclusively as it used to do, we might get on, perhaps, a little faster. Practical minds, on the other hand, could not afford the time, nor do they possess the special aptitudes for dipping deep into the stream of pure science. They are content to work on, and respectfully await what the scientific intellect is pleased to bestow; but, at the same time, reserving their right to grumble if what they get is not quite up to their expectations. They had, above all things, a special right to complain, and even to protest, against the theoretical scientist losing his head, and swelling the cry of the ignorant multitude. On more than one occasion in recent years practical men have had to stand aside, and look on with bewildered incredulity at projects which their practical instinct convinced them were doomed to disappointment, but against which they dare not raise a whisper—for they were only "mere practitioners." Mr. Smith did not exactly say all this; but we can easily imagine he meant it.

Quite in keeping with all this was his advice to students of all classes—advice which, as Professor Adams remarked, was

Digitized by Google

as applicable to the old as to the young. Matthew Arnold, when lecturing on lucidity, told us not to think but to be patient. All things come to him who knows how to wait, is his favourite proverb. Mr. Smith, too, has his favourite maxim. It is a very ancient one, and it comes from the East, where wisdom was invented but never patented, namely,—Be quick to learn, my child, how to say *I do not know*. What agonies mankind would have been spared if that simple lesson in modesty and sincerity had been universally learnt! It is a compendium of all the virtues in the business of this life to them who have sense to apply it. But to them who have not, its merits seem vague, visionary, and unproductive, therefore we will not descant upon them. Suffice it to say that in Mr. Willoughby Smith's estimation minding your own business, closing your mouth generally, and opening your ears always, is the way to become wise; and, with due perseverance and patience in that course, your reward is certain—practical advice with which we cordially agree, and which appropriately concluded a very practical address.

LITERATURE.

The Electric Lighting Act, 1882, *the Acts Incorporated therewith, the Board of Trade Rules, together with Notes and Cases.* By C. Higgins, M.A., and E. W. W. Edwards. London: W. Clowes and Sons.

If the electric light ever becomes as common an illuminant as gas, it will be necessary for many of those interested in it to know something of the various Acts of Parliament and rules of the Board of Trade, &c., under which the light will frequently have to be supplied. The work before us annotates and explains the recent Act, as well as gives information upon various technical matters, the latter being chiefly compiled from the evidence of those examined before the Select Committee. The copious references to cases will be found of great value, as it is by these decisions one learns exactly what can be done and what cannot be done under this and other Acts of Parliament. In appendices are given the "Board of Trade Arbitrations, &c., Act, 1874," "Telegraph Act, 1878," and the "Rules of the Board of Trade with respect to Applications for Licenses and Provisional Orders." Altogether the work will commend itself to those who desire information. It is, in addition, well printed—a valuable feature, but one which in these days is not always thought of much account.

Useful Rules and Tables. By Professor W. J. M. Rankine. Sixth Edition. Revised by W. J. Millar, C.E. With an Appendix by A. Jamieson, C.E. London: C. Griffin and Co.

Professor Rankine's literary works were of a type and character which marked a new era in books pertaining to engineering, hence they stand their ground against the many meretricious books that have since been written. There is no royal road, and the engineer who wants the subject brought down to his comprehension is incomparably inferior to the engineer who determines to raise the level of his comprehension so that he can really understand the laws under which his work is to be tested. No doubt a good deal can and has been done by mere rule of thumb, but even this and acquired experience will be fatal to success if trusted too much. Professor Rankine never wrote for those who professed themselves ignorant of the fundamental rules of mathematics. The work before us, however, can hardly be called a literary production, it is more a compilation of rules of formulæ by a competent hand. That it is found useful is proved by this being the sixth edition. Mr. Millar is a competent editor, and we have no doubt was wise in adding an appendix of electrical formula to the book. This appendix by Mr. Jamieson fills sixty-two pages, and is an *olla podrida* of rules, formulæ, descriptions, &c., compiled from a variety of sources, showing the compiler's wide reading. The book will be found exceptionally useful for reference, and its contents may be taken to be trustworthy, after having been subjected to such long use and careful supervision.

Les Téléphones Usuels. Transmetteurs et Récepteurs Bell, Edison, Hughes, Ader, Blake, Crossley, Gower, &c. Par Charles Mourlon. Brussels: A. N. Lebèque et Cie.

Some of the elders among us can remember when the science of chemistry was discussed within the covers of an ordinary sized volume. We have seen something of its wonderful development, and watched how its votaries more and more gave up the study of the subject as a whole in favour of special branches, each of which contained material for the work of a lifetime. Electrical science is fast following in the footsteps of the sister science, and splitting up into branches. We shall soon have specialists in telegraphy, telephony, electro-chemistry, and so on; indeed, our bookshelves are beginning to show signs of these special studies in *brochures* devoted to one or other branch of the subject. The one before us is a simple work, describing the various articulating telephones, or, rather, the various apparatus connected with articulating telephony. Telephonic apparatus is, by the author, said to be of two kinds, "Les Téléphones Musicaux" and "Les Téléphones d'Articulation," the latter only being dealt with in the book. A number of illustrations are given besides those of the instruments themselves, showing the methods of connecting, insulators, &c., central station, switching apparatus, and so on. The book partakes somewhat of the nature of a firm's price list, the author being the manager of Mourlon and Company's factories, and the work giving lists of prices for installations of various kinds. These lists, however, occupy only some four pages out of a hundred. A list of publications on telephony is given at the end of the book.

Electric Telegraphy. By Professor Dr. E. Zetsche. Leipsic: J. J. Webber, 1883.

This is an elementary handbook by one of the ablest and most painstaking of German writers. The first part of the book refers to the apparatus used, describing ordinary batteries, thermo-batteries, and the dynamo, besides treating of the instruments and laws by which measurements are made. We next come to telegraphy proper, and find the early experiments of Gauss and Weber, of Steinheit, of Cooke and Wheatstone, &c., described and illustrated, gradually coming to the descriptions of the more modern instruments, such as various sounders, writing apparatus, &c. Cable work, duplex and multiplex working, &c., are all discussed. There is nothing much that is new in the book, but for four marks—practically four shillings—we get in German a far better illustrated and more compendious handbook than can be obtained in England at a similar cost. At the end of his book Dr. Zetsche gives a statistical table relating to telegraphy in 1881. It will be interesting in the future to note the effect which the development of telephony will have upon telegraphy, and especially upon local telegraphy. To those who find a pleasure in reading the German character—not German in Roman type—we commend this book.

The Telephone Case.—The case of the United Telephone Company *v.* Harrison Cox-Walker and Co. came on before the Master of the Rolls and Lords Justices Lindley and Bowen on Tuesday last. It will be remembered that the plaintiffs obtained, in April last, an injunction against the defendants for infringing the Bell telephone patent. This was an appeal against the above judgment by the defendants. The case was not concluded when we went to press, and was to be heard again on Friday. We shall, therefore, defer our report until next week.

A GUIDE TO PRACTICE IN THE SUBMARINE CABLE TESTING ROOM.

No. XIII.

In the practical execution of the joint test three observations have to be made for the cable—that is to say, three readings are taken. These readings are not to determine any numerical value for the deflections, but they must not be larger than a certain relative amount, and their direction on the scale must be determinate. The first of these is the *inductive charge*, the second shows the *amount of leakage*, and the third is the *inductive discharge*.

The inductive charge (also called the immediate charge) is explained by saying that when the battery key is depressed, and a charge thus sent into the joint, a corresponding charge is induced in the water in the trough; and if we immediately connect the galvanometer to the latter by putting down C (see Figs.), this induced charge is observed by the deflection which it causes—it may be towards the right hand, the spot being arranged in the centre of the scale. The second operation is really a repetition of the first, the difference being that the battery key is kept down for some minutes before the galvanometer key is depressed, and, in addition, the condenser key D is kept down at the same time. This has already been referred to as the accumulation and measurement of the leakage from the joint. The deflection will be smaller than that from the induction charge, but in the same direction on the scale. It has been suggested that the deflection from the induced charge is really caused by leakage, and is not inductive but direct; but the fact now stated that the deflection is larger than that from the accumulated charge seems to disprove the idea, although it is at first sight favoured by the direction on the scale being the same in both cases. The third observation, that of the inductive discharge, is effected by releasing the condenser key D and instantly depressing C, and then releasing B, touching down A, when a deflection is seen on the scale in the opposite direction to that of the two first, but of the same value as that given by the inductive charge; that is, the spot travels over the same number of divisions in each of these two cases. The cable is thus put to earth, and the charge removed. It is said to rush out of the cable, and thereby causes an inductive charge in the opposite direction to that resulting from the first operation, and so it is styled an inductive discharge. These inductive charges are interesting features in the joint test, and have been the subject of discussion involving opposite opinions on the part of some who have advanced different theories as to their real interpretation. We cannot stop to consider these just now, but must proceed with the practical duties preceding and attending the operation, which are as follow. It is usual to keep a book specially for the record of joint tests. It is ruled in columns containing the joint numbers, which run consecutively, the numbers of the several coils which each joint unites, the machines to which they belong and other particulars. When a fresh coil of core is to be joined to the former length passing through any machine an order is given out to the jointer detailing the coil numbers, &c., and accompanied by a leather label bearing the number of the joint stamped on it. At the same time the entry is made in the joint book of the particulars contained in the order. When the joint is finished the jointer returns this order with the hour and minute of completion recorded on it. Six hours are generally allowed between the time of finishing and that of testing; that is, the joint should soak in water for six hours before allowing it to be tested. Thus, if a joint were finished at two it should not be tested before eight o'clock, and this latter hour is entered in the book as the proper time for the operation. The electrician on duty will examine the joint book from time to time, and order the connections outside to be made for the proper hour. The learner will understand that while a joint is being made in a length which is being sheathed on a machine that particular section of cable cannot be tested. When the jointer is ready to begin he requests the operators in the testing room to disconnect that machine. Referring to our explanation of the large commutator in Nos. I. and V. of this series, it will be seen what this means. In this particular instance there is no actual disconnection within the room beyond separating from the electrometer (No. V.). It is only necessary to be sure that the plug connecting the horizontal with the upright or cable (or core) bar is not inserted, so that there can be, for example, no battery current passing in the section. But the core lead which is joined to the back of the commutator outside the testing room must be disconnected from the end of the core, part of which is passing through the machine, because the joint is to be made between this end and one end of the fresh length or drum of core, and the other end of this latter will in its turn be connected to the lead just removed from the nearly used-up core still being sheathed.

As regards the jointer's request for disconnection just mentioned, it may be noted that no one is allowed on any account to disconnect any of the leads or sections outside in the cable shop without orders from the electrician. This rule requires very strict enforcement, for it unfortunately happens that if an instance does occur nobody will ever own to having done it.

Of course a sufficient length of core is always left coiled in the core tank to allow the end to be jointed without stopping the machine. It is customary to allow about 40 minutes from the time at which the request for disconnecting the machine was made until the lead at the back of the commutator need be joined to the fresh coil of core. The battery-man often does this sooner without direct instructions; but, generally speaking, as soon as the joint order is returned by the jointer, it is imperative to take a short copper resistance test on the bridge to be sure that the proper coil has been added, for each coil is specially appointed to its place in the cable. Very often two coils are joined on, having been previously jointed together (end to end, of course). In another book recording the composition of each machine section, the numbers, lengths, resistances, &c., of each coil are entered in consecutive order, the total length and copper resistance at any time being apparent at a glance. When, therefore, a fresh coil is added, the *total* resistance is known, and since the last C R (copper resistance) test before joining on is recorded in its appropriate column, a test at this time ought to show that the proper addition has been made. Suppose, for example, that the section gave 120 ohms for C R before the coil was added, and that the fresh coil had 10 ohms' resistance (as known from the previous core test), the section, after the joining on of this coil, ought to show when tested 130 ohms instead of 120. There is generally a difference of from 3 to 5 per cent. between the copper resistance of a given length tested as core, and the same tested as cable; but, if the result in the case before us differed considerably from the amount to be expected under the given conditions, there is something wrong, and the matter must be at once inquired into. This precautionary test should always be taken when a joint has been made in a working section.

We will now suppose that a joint is entered in the joint book for testing at 3 p.m. It will, under ordinary circumstances, have been finished at 9 a.m., and placed in water. The battery-man on duty will probably have made the necessary connections outside the room shortly before three, but, if not, instructions must be given in time. We require one lead connecting with the conductor of the cable, and one for the trough (or the plate in the water), and, further, one end of the section must be free, that is, insulated. In a room where the large commutator is arranged as we have suggested, we should connect with the cable by a plug joining the cable bar by a contact-piece from which a lead may go to the testing table (see Fig. 23); the core end would either be insulated at the core bar, seen in Fig. 9, No. V., in the electrometer test, if the fresh coil had been joined to the core lead, or more probably the end would be free at the core tank, and the battery-man would join the trough to a lead whose other end would be joined to the back of one of the ebonite terminals on the commutator. To this we should join a lead which is connected to a point on the testing table (Fig. 23), and we have thus our arrangements for the test.

A separate set of keys, &c., and a separate galvanometer

Digitized by Google

and condenser, particularly the latter, are kept in readiness for this operation. The condenser should, as remarked in the case of other tests, be always short-circuited when not being used. A large one is not necessary for this test, and a form is sometimes employed which is not arranged for joining the poles by a plug. In this event a separate lead should connect each pole with earth, one of these going first to a contact point which can be put to earth by depressing a key piece. This will be illustrated presently.

Where a long cable is being manufactured there may be thirty or forty joints to be tested daily, and there is not much spare time, as the joint is usually "wanted" at or close to the hour fixed on for testing it, and sometimes the six hours' interval, after finishing its manufacture, is unavoidably shortened (though never by more than three hours) if the machine has worked faster than was expected. It is

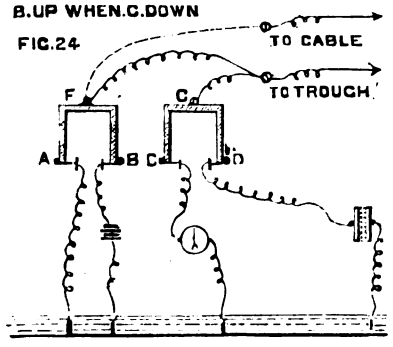

FIG. 24.—For insulation of trough.

"wanted" in the first place that it may be "served," that is, covered with yarn as the whole of the core is before entering the sheathing machine, and secondly, that this operation may be completed in good time to prevent stoppage of the machine. We may here repeat the injunction to avoid most carefully doing anything which may bring about this result. It would be regarded as worse than a blunder, and, therefore, the electrician will do well to look over the connections, and assure himself that everything is in perfect order a few minutes before the time. He should see that all connecting screws are tight, and all leading wires, short or long, are in their right places; that there is nothing wrong with the lamp, and that the adjustments of the galvanometer are in order—that is to say, that the spot is properly reflected and deflects

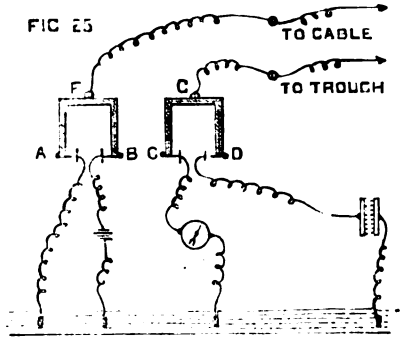

FIG. 25.—For inductive charge.

freely, and that the sensitiveness of the mirror (magnet) is not too great, for it is possible that the large directing magnet of the instrument may have been shifted from its proper position. Generally speaking, the battery-man may be trusted to have arranged his connections outside rightly, so that the operator need not go out to examine them. This necessity may, however, arrive, as we shall see, but, if so, it will become apparent during the course of the test.

A separate battery is usually, though not always, employed for the test. If it be used for others there will probably be a battery commutator for dividing the number of cells, as previously explained in No. VII. (Fig. 13). In this case the plug must be inserted in the proper place for the 200 or 300 cells which are generally used. The first thing to be done is to ascertain the sufficient insulation of the trough, since, if there be any leakage to earth through its surface, or, rather, that of the stand, the conditions of the test would be disturbed. We desire to collect the leakage from the joint in the condenser and observe it by discharging through the galvanometer, and if the trough were not well insulated, this object would be frustrated, and besides this there would be a constant current passing to earth, and the galvanometer indications would be misleading. One way of determining the question would be by removing the battery leading wire from the cable and attaching it to the wire of the trough (see Fig. 24, in which the dotted line shows where the lead is removed). Then depress D and B, and instantly releasing B, touch down C. By this means the trough is charged, the condenser takes up the charge, and it is discharged through the galvanometer, producing a deflection which represents the full charge from the battery. Then repeat the observation (first short-circuiting the condenser

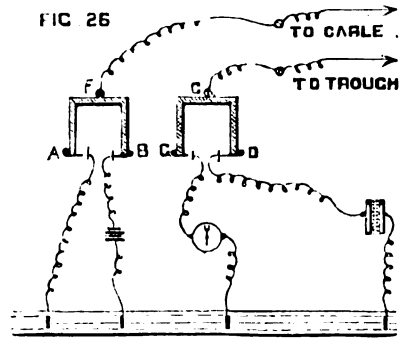

FIG. 26.—For accumulation of charge. C down after three minutes.

for a moment or two), but keep down B (and D) for, say one minute, and discharge as before by touching down C. If the deflection is so much smaller than the first that more than 2 or 3 per cent. loss of charge is the result, the trough is not well insulated, because it allowed too much of the charge to escape to earth. In the illustration of the test with different connections we shall show another way of performing this operation.

Supposing the result to be satisfactory we may proceed. The battery wire will be returned to its former connection, and the condenser briefly short-circuited. Having the spot of light in the centre of the scale at zero, depress C and immediately afterwards B also, keeping an eye on the scale (Fig. 25). If the deflection is of the right amount, a point

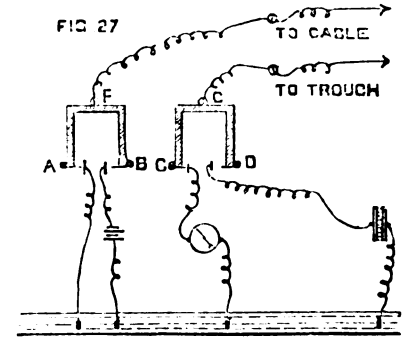

FIG. 27.—For inductive discharge.

depending on prearrangement of the galvanometer and known beforehand, release C and clamp down B and D. The charge is now entering the cable (and joint), and any leakage through the latter is passing to the condenser, and there accumulating (Fig. 26). This may continue for any period chosen, say three minutes. At the end of this time touch down C; this connects the galvanometer to the condenser, and the accumulated charge in the latter is discharged through the former to earth. Supposing the deflection thus caused to be no larger than the amount fixed, it is concluded that the leakage is not too great; at once, therefore, release B and touch down A and C. The joint is hereby discharged to earth, and the *inductive* discharge from this trough causes a deflection on the scale in direction opposite to the two former deflections, and equal in amount to the first (Fig. 27). The joint may now be passed, that is, a label stating the fact

Digitized by Google

is sent out to the cable shop. [Note—Fig. 28 illustrates more clearly the connections in the room; the *dotted* lines are *outside* of the room from the back of the commutator.]

This account of the test is appropriate to the arrangement of the connections as given in the figures, and though, as already stated, there are other ways of connecting up for this operation the principle is the same for all. But as these various connections are always confusing to a beginner, and since all testing rooms have not the same modes of arranging the tests, it is necessary to give more than one example. The standard fixed for the amount of deflections to be allowed is not rigidly binding in all cases, but whenever there is any doubt as to the result, if the deflections seem to exceed the proper limit

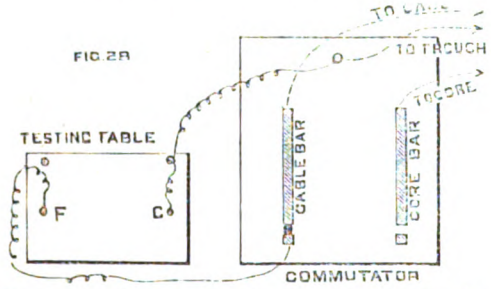

FIG. 28.—Connections for joint test in room. F and G refer to F G in Figs. 23 to 27.

(under the governing conditions), a piece of the core must be put in the trough and tested in the same way, when, if the same deflections are obtained, the joint may be passed. The latter is merely lifted out and wiped dry, and the length pulled along some little way, and the core placed in the water and secured by the hooks. The various contingencies which may cause trouble or irregular results in the test, and which must be taken into consideration in pronouncing on the quality of the joint, will be enumerated presently. We will first give two other plans of connections and take the test with them, and also show how to proceed when using the electrometer instead of the galvanometer and condenser for the same purpose.

CANTOR LECTURES.*

DYNAMO-ELECTRIC MACHINERY.

BY PROFESSOR SILVANUS P. THOMPSON, B.A., D.SC., M.S.T.E.

Lecture II.—The Dynamo in Practice.

(CONTINUED FROM PAGE 238.)

Armatures.

The armatures of dynamos of the first class may be roughly classified in three groups, according to the manner of arranging the coils. These three groups are—

(1.) *Ring armatures*, in which the coils are grouped upon a ring, whose principal axis of symmetry is its axis of rotation also.

(2.) *Drum armatures*, in which the coils are wound longitudinally over the surface of a drum or cylinder.

(3.) *Pole armatures*, having coils wound on separate poles, projecting radially all round the periphery of a disc or central hub.

(To these we shall add a fourth form, namely, that of *Disc armatures*, when we deal with dynamos of the second class.)

The object of all these combinations is to obtain the practical continuity of current spoken of in section *t* of the first lecture. Some of the individual coils should be moving through the position of maximum action, whilst others are passing the neutral point, and are temporarily idle. Hence a symmetrical arrangement around an axis is needed. Ring-armatures are adopted in practice in the dynamos of Pacinotti, Gramme, Schückert, Gülcher, Fein, Heinrichs, De Meritens, Brush, Jürgensen, and others. Drum armatures are found in the Siemens (Alteneck), Edison, Elphinstone-Vincent, Laing, and other machines. Pole-armatures are used in the dynamos of Allen and of Lontin. There are several intermediate forms. The Bürgin armature consists of eight or ten rings, side by side, so as to form a drum. The Lontin (continuous-current dynamo) has the radial poles affixed upon the surface of a cylinder. The Maxim armature is a hollow drum wound like a Gramme ring, and has therefore a great quantity of idle wire on the inner surface of the drum. The Weston armature has the drum surface cut up into longitudinal poles; there is a similar armature by Jablochkoff, in which the poles are oblique.

Ring armatures are found in many machines, but the ingenuity of inventors has been exercised chiefly in three directions:—The securing of practical continuity, the avoidance of Foucault currents in the cores, and the reduction of useless resistance. In the greater part of these machines the coils that form the sections of the ring are connected in series, the end of one to the beginning of the next, so that there is a continuous circuit all round, an attachment being made between each pair to a bar or segment of the collector. Most inventors have been content to secure approximate continuity by making the number of sections numerous. One inventor, Professor Perry, has built up a ring with coils wound obliquely, so that the one coil reaches the neutral point before the preceding one has passed it. I cannot help doubting the advantage of this arrangement; which, moreover, presents mechanical difficulties in construction. Pacinotti's early dynamo had the coils wound between projecting teeth upon an iron ring. Gramme rejected these cogs, preferring that the coils should be wound round the entire surface of the endless core. To prevent wasteful currents in the cores, Gramme employed for that portion a coil of varnished iron wire of many turns. In Gülcher's latest dynamo, the ring core is made up of thin flat rings cut out of sheet iron, furnished with projecting cogs, and laid upon one another. The parts of the coils which pass through the interior of the ring (in spite of the late M. Antoine Breguet's ingenious proof that some of the lines of force of the field bent round and turned back into the core in this interior region) are comparatively idle. They cut very few lines of force as they rotate, and therefore offer a wasteful resistance. Inventors have essayed to reduce this source of loss, by either fitting projecting flanges to the pole pieces (as in Fein's dynamo) or by using internal magnets (as in Jürgensen's dynamo), or else by flattening the ring into a disc form, so as to reduce the interior parts of the ring-coils into an insignificant amount. This is done in the dynamos of Schückert and of Gülcher. In the latest form of Gülcher's dynamo the field magnets, front and back of the ring, are united on the right and left sides in a pair of hollow pole pieces, which form cases over the ring, covering a considerable part of it. The collector is identical with that of Gramme, but very substantial.

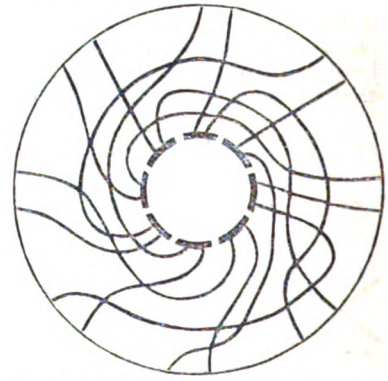

FIG. 22.—Alteneck-Siemens Winding (old).

The drum-armatures may all be regarded as modifications of Siemens's well-known longitudinal shuttle-form armature of 1856, the multiplicity of sections of the coils affording practical continuity in the currents. In some of Siemens's machines the cores are of wood, overspun with iron wire circumferentially, before receiving the longitudinal windings. In another of their machines there is a stationary iron core, outside which the hollow drum revolves; in other machines, again, there is no iron in the armature beyond the driving-spindle. In all of the Siemens armatures the individual coils occupy a diametral position with respect to the cylindrical core, but the mode of connecting up the separate diametral sections is not the same in all. In the older of the Alteneck-Siemens windings the sections were not connected together symmetrically, the connexions (for an eight-part collector) being as in Fig. 22. But in the more recent machines a symmetrical plan has been adhered to, as shown in Fig. 23.

In this system, as in the Gramme ring, the successive sections of coils ranged round the armature are connected together continuously, the end of one section, and the beginning of the next, being both united to one segment or bar of the collector. A symmetrical arrangement is, of course, preferable, not only

* Reprinted from the *Journal of the Society of Arts*.

Digitized by Google

for ease of construction, but because it is important that there should never be any great difference of potential between one segment of the collector and its next neighbour; otherwise there will be increased liability to spark, and form arcs across the intervening gap. In Edison's modification of the drum-armature, the winding, though symmetrical in one sense, is singular, inasmuch as the number of sections is an odd number. In the first machines there were seven paths, as shown in Fig. 24, taken from Edison's patent specification. In his latest giant machines the number of sections is forty-nine. One consequence of this peculiarity of structure is that, if the brushes are set diametrically opposite to one another, they will not pass at the same instant from section to section of the collector; one of them will be short-circuiting one of the sections, whilst the other is at the middle of the opposite collector. The armature of these latest of Edison's dynamos

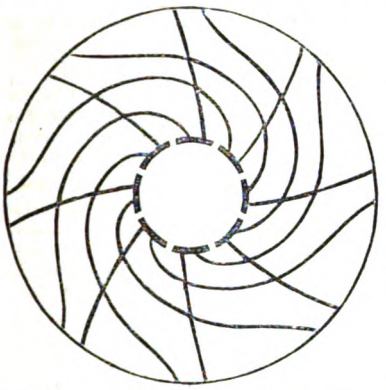

Fig. 23.—Alteneck-Siemens Winding (new).

is not wound up with wire, but, like some of Siemens's electro-plating dynamos, is constructed of solid bars of copper, arranged around the periphery of a drum. The ends are connected across by washers or discs of copper, insulated from each other, and having projecting lugs, to which the copper bars are attached. Such discs present much less resistance than mere strips would do. The connections are in the following order:—Each of the forty-nine bars of the collector is connected to one of the forty-nine discs at the anterior end of the drum, which is connected by a lug-piece on one side, to one of the ninety-eight copper bars. The current generated in this bar runs to the further end of the machine, enters a disc at that end, crosses the disc, and returns along a bar diametrically opposite that along which it started. The anterior end of this bar is attached to a lug-piece of the next disc to that from which we began to trace the connections, it

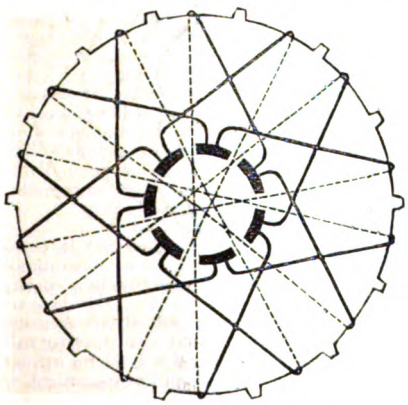

Fig. 24.—Edison's Winding.

crosses this disc to the bar next but one to that first considered, and so round again. The two lug-pieces of the individual discs at the anterior end are, therefore, not exactly opposite each other, diametrically, as the connections advance through $\frac{1}{49}$ of the circumference at each of the 49 paths. It is noticeable in this machine that the collector is very substantially built, and that a screen is fixed between the collector and the rest of the armature, to prevent any copper-dust from flying back or clogging the insulation between the bars or discs. There are no fewer than five pairs of brushes, the tendency to sparking being thereby greatly reduced. The core of the armature is made of very thin discs of iron,* separated, by mica or asbestos paper, from each other, and clamped together. Some exception may be taken to the use of such stout copper bars, as being more likely to heat from local currents than would be the case if bundles of straps, or laminæ of copper were substituted. And, indeed, the presence of a 4-horse power fan to cool the armature, is suggestive that continuous running is liable to heat the armature.

Before passing on from the subject of armatures, it is worth while to mention the peculiarity of form of the Bürgin armature, which has already been spoken of as consisting of eight, or in the newest Bürgin machines, as constructed by Mr. R. E. Crompton, of ten rings, set side by side.* Each ring is made of a hexagonal coil of iron wire, mounted upon light metal spokes, which meet the corners of the hexagon. Over this hexagonal frame, six coils of covered copper wire are wound, being thickest at the six points intermediate between the spokes, thus making up the form of each ring to nearly a circle. Each of the six coils is separated from its neighbour, and each of the ten rings is fixed to the axis $\frac{1}{60}$ of the circumference in advance of its neighbour, so that the sixty separate coils are in fact arranged equidistantly (and symmetrically, as viewed from the end) around the axis. There is a 60-part collector, each bar of which is connected to the end of one coil and to the beginning of the coil that is one-sixtieth in advance; that is, to the corresponding coil of the next ring. This armature has the great practical advantages of being easy in construction, light, and with plenty of ventilation.

In the Elphinstone-Vincent dynamo there is a drum-armature of a somewhat distinct order, the separate coils being made of a rectangular form, and then laid upon the sides of a hollow papier-maché drum in an overlapping manner, and curved to fit it. The field is a complex one, with six external and six internal poles, and is very intense, owing to the proximity of these poles. The parallelogram-shaped coils are connected together so as to work as three machines, and feed three pairs of brushes; which may again be united, either in series or in parallel, or may be used to feed three separate circuits.

(TO BE CONTINUED.)

* Discs of thin iron for a similar purpose are found in the dynamos of Jablochkoff, Weston, and Gülcher.

* The Bürgin armature exhibited on the evening of the lecture was kindly lent by Messrs. R. E. Crompton and Co.

EASTERN TELEGRAPH COMPANY (LIMITED).

The twenty-first half-yearly ordinary general meeting of this Company was held on the 25th instant, at the City Terminus Hotel, under the presidency of J. Pender, Esq., M.P.

Mr. Lewis Wells having read the notice calling the meeting,

The Chairman moved the adoption of the report and accounts, and after referring to the full information contained therein, stated that the revenue for the six months ended 30th September last had been £341,151, against £282,834 in the corresponding period of 1881, being an increase of £58,317. Analysing these figures, they found a very satisfactory growth of the traffic throughout their system, with one or two exceptions. The ordinary expenses of the Company had amounted in the half year to £69,809, which was an increase of £2,311, as compared with the corresponding half of 1881. The main cause of this increase was their having opened four new stations at Athens, Karystos, Trieste, and Corfu, and they had had increased expenses owing to the increased volume of the traffic from Egypt and other places during the war. The repairs to the cables, &c., had cost £52,801, which was an increase of £5,573. Full particulars were given in the accounts in Abstract "C" of this expenditure. Of course this exceptional expenditure would be always more or less fluctuating. The general expenses in London had amounted to £6,670, or an increase of £149. The working expenses at the stations had amounted to £50,387, or an increase of £2,969, as compared with the same half of 1881. The opening of the four new stations had caused the great bulk of the increase. The amount carried forward in that half year would be £56,836, or £27,332 more than in the corresponding half year. This was after paying a bonus of 1s. per share on the ordinary capital, making with the previous payment a return for the half year at the rate of 6 per cent. per annum. Up to the present time they had been in the habit of paying a dividend at this period of the year at the rate of 5 per cent., leaving the bonus for the end of the year. But they were so satisfied with the position of the Company that they thought they might give a proportion of the bonus this half year, and he hoped when he met them next half year that they would be able to state that the dividend had been 6 per cent. for the year. He then reminded them of the breaks or interruptions in their system to which he had alluded at the previous meeting, and said that they had since been effectually repaired. One very important interruption in the Bay of Biscay had been rectified, the cable having been picked up from 2,700 fathoms of water, a fact which proved that they had what he had so often maintained—a property. He stated at the last meeting that they were in a very peculiar position with regard to their ships, as it was their duty to maintain, if possible, telegraphic communication between Egypt and England. This had been accomplished satisfactorily from a commercial point of view to themselves, and satisfactorily also as regarded broad national interests, and they had received an ac-

Digitized by Google

knowledgment from the Government of the services rendered by the Company during the recent war. He next referred with satisfaction to the communication by cables which had been established between Alexandria and Port Said. Thus, thanks to the Government and the broad views of the Khedive, they had been able to make an arrangement with the Suez Canal Company, by which, in future, they would have an alternate line along the Suez Canal, connecting the Suez end with India and the Port Said end with Egypt. After commenting on the importance of this operation, he alluded to the eventful period which the last half year constituted in the Company's history, and observed that, notwithstanding the ups and downs and the interruptions to their Indian traffic, the receipts in the half year had been the largest that they had ever had. He next referred to the views enunciated at the last meeting with regard to the services which the staff in Egypt had rendered, and stated that the Board had recognised those services by a money grant, which would be an incentive to the officers on any future occasion.

The VICE-CHAIRMAN (the Marquis of Tweeddale) having seconded the motion,

A brief discussion followed, in the course of which the zealous services which had been rendered by the staff generally, and particularly in Egypt, were warmly acknowledged by several speakers.

The CHAIRMAN, at the close of the discussion, stated that they would take advantage of a favourable opportunity (and circumstances were tending in that direction, the Bank rate having been reduced) to replace their debentures, and, of course, they would do it at the cheapest possible rate. He entirely concurred with the remarks made as to the advisability of replacing to reserve fund the amount which had been taken from it, a strong reserve adding very greatly to the stability of the Company. He expressed his pleasure at the eulogistic remarks which had been made regarding the services of the staff, and assured them of the hourly services which had also been rendered necessary from the Board. With regard to the proposal to increase the remuneration of the directors, on behalf of his colleagues he could say that they were satisfied at present, but when the time came they would not oppose such a proposal.

The report was unanimously adopted, and the retiring directors, Lord S. A. Cecil and General Lord Alfred Paget, were re-elected, as were also the auditors, Mr. Henry Dever and Messrs. Quilter, Ball, and Co.

A cordial vote of thanks to the chairman terminated the proceedings.

We shall publish a full report of this meeting in another issue.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.

An extraordinary general meeting of this Company was held on the 25th inst., at St. Michael's Hall, George-yard, Lombard-street.

Major WOOD having read the notice calling the meeting,

Sir H. D. WOLFF, M.P., who presided, moved the confirmation of the first of the special resolutions passed at the meeting on the 10th inst., the effect of which was to reduce the capital of the Company from £1,398,200, divided into 69,910 shares of £20 each, into £1,048,650, divided into the same number of shares of £15 each.

Major WOOD seconded the motion, which was carried.

The CHAIRMAN then moved the confirmation of the resolution, substituting for Article No. 40 another Article similarly numbered, authorising the Board to appoint a managing director who might be a member of the Board, but who should not be subject to retirement by rotation.

Mr. H. WEAVER seconded the motion, which was carried.

Mr. PIKE said, with regard to the last resolution, that he would not repeat the arguments that he had used on a former occasion, but he thought everyone would be willing to recognise the great services which had been rendered by the Board, and there was no doubt that the best way to do so would be by allotting them in the way in which he (Mr. Pike) had suggested a certain number of the shares recovered. He might point out this fact—that before the directors could fight the battle successfully, as they had done, they had to displace the old directors, and, if there was no other circumstance in their favour, that alone would entitle them, he contended, to some substantial acknowledgment at the hands of the shareholders. He then moved the following resolution:—"That in view of the great services of the Board in relation to the late litigation, by which a very large sum of money has been recovered for the Company, and the Company placed on a sound footing, and as a recognition by the shareholders of the successful result of their labours, the directors be requested to accept 700 of the shares acquired by the Company as part of the settlement, and now held by trustees for the Company, to be divided among the members of the Board as they may determine."

Mr. SUTTON, in seconding the motion, said that the action of the Board had resulted in the recovery of £150,000, which was previously absolutely lost. This amount would not have been recovered, he contended, but for the great skill and diligence displayed by the directors. He, therefore, thought that the directors for having recovered such a substantial sum should be suitably rewarded by the shareholders. The amount proposed to be given them was only equal to £5,000. Some gentleman had thought that the amount should be only £3,000, but no doubt that gentleman would agree that the extra £2,000 which was proposed by Mr. Pike's resolution would not make much difference to a large company like theirs, which he had no doubt was about to enter on a career of prosperity.

Mr. GODFREY opposed the motion, and said it must be remembered that for four or five years the shareholders had been without a dividend, and in that way alone there had been a loss to them of between 20 and 25 per cent. In addition to that the market price of the shares stood at more than 60 per cent. discount. The chairman and directors had received their salaries for doing their duty, and he did not think they had done more than their duty. Under these circumstances he should be happy to see some of the directors themselves decline to assent to the proposal.

Mr. GADESDEN also opposed the motion, and argued that the real work in connection with the litigation had after all been conducted by the solicitors, counsel, officers, and others. The whole of the costs of counsel and everything in connection with the case was under £5,000, whereas it was proposed to vote the directors a similar amount for really doing next to nothing in the matter.

Mr. WARING supported the motion.

Mr. GADESDEN moved an amendment to the effect "That the number of shares to be given to the directors should be 350."

Mr. WALTON seconded the amendment.

The CHAIRMAN put the amendment, which he declared lost. He then put the original motion, and declared it carried, stating that 18 had voted for it, and 14 against it.

The proceedings then terminated.

ORIENTAL TELEPHONE COMPANY (LIMITED).

An extraordinary general meeting of the members of this Company was held at the City Terminus Hotel, on the 24th inst. J. Pender, Esq., M.P., presided.

The CHAIRMAN, in opening the proceedings, said: Gentlemen, the secretary will read the notice convening the meeting.

The SECRETARY accordingly read the notice and subsequently read the minutes of the last meeting—the extraordinary general meeting held at the offices of the Company on the 4th ult.

The CHAIRMAN: Is it your pleasure that those minutes be signed? Those in favour say Aye. To the contrary No. The ayes have it. Having signed the minutes, he continued: Gentlemen, this is a special meeting called for the purpose of altering the Articles of Association. When I last had the pleasure of addressing you I referred to the great progress which the Company had made. I also referred to the fact that we were in negotiation with parties in Bombay for the formation of a company. That has been completed. It requires after the end of the year two or three months—in fact, three months—before we can get home all the accounts and submit our annual balance-sheet, and therefore we thought, as some applications had been made by different shareholders as to dividend, that it would be desirable we should have the power to declare interim dividends. We had the money, and therefore we thought, as these articles must be introduced into our articles to enable us to pay interim dividends, that it was as well to do so at once, and at the same time pay an interim dividend, which we propose to declare. That is the object of the meeting, and the first resolution I have to submit is as follows:—"That the Articles of Association of the Company be, and the same hereby are altered by rescinding Article 48, and that in lieu thereof the following article shall henceforth be Article 48, viz.:—'48. Every member shall have one vote for every share held by him, and every holder of a share warrant shall (subject to the provisions of Clause 23 being complied with) have one vote for every share warrant held by him. In case of an equality of votes at any general meeting or poll, the chairman shall be entitled to a second or casting vote. That is one article we propose to alter.'"

Mr. P. CARNEGY, C.I.E.: I beg to second that resolution.

The CHAIRMAN: If any gentleman has any remark to make before I put that resolution I shall be glad to hear him. According to my idea it is merely making some amendment in the Articles of Association, which, probably, would have been better had they been done in the first instance. Those in favour of that resolution please hold up their hands. To the contrary. Carried unanimously. The next resolution is as follows:—"That the Articles of Association of the Company shall be, and the same hereby are altered by the following article being inserted after Article 79, viz.:—'79A. The directors may of their own authority from time to time determine on, and declare an instalment to be paid to the members in proportion to the amount paid up or deemed and taken as paid up upon their shares on account, and in anticipation of the dividend for the current year, but so that the aggregate amount of such instalments in any one year shall not exceed a dividend at the rate of 20 per cent. for the year.'"

Colonel GOURAUD: Mr. Chairman, I have great pleasure in seconding that resolution. The terms of it are so obviously in the interests of the shareholders that I do not think any special remarks from me are necessary.

The CHAIRMAN put the motion in the usual way, and declared it carried unanimously. Continuing, he said: The next resolution is as follows: "That the Articles of Association of the Company be, and the same hereby are altered by rescinding Article 82 of the Articles of Association of the Company, and that in lieu thereof the following article shall henceforth be Article 82, viz.:—'82. Every dividend and instalment of dividend or interest shall belong and be paid (subject to the Company's lien) to the members who shall be on the register at the date when such dividend or instalment of dividend shall be declared, or interest shall be payable, notwithstanding any subsequent transfer or transmission of share.'"

Sir A. ARMSTRONG: I beg to second that.

The CHAIRMAN put the motion, and declared it carried unanimously. Continuing, he said: Now, gentlemen, these resolutions have to be confirmed, and when that is done we shall be in a position to declare an interim dividend. We are not in a position to declare an interim dividend until once those articles are confirmed at another meeting. We must go through the legal form, and that other meeting will be held as soon as it can be legally. At that meeting the dividend will be declared.

The SOLICITOR: These resolutions will be confirmed, and then the dividend can be declared.

Colonel GOURAUD: The confirmation being necessary by the Articles of Association?

The CHAIRMAN: Yes, that will enable us probably to pay this dividend within the next fortnight or three weeks. Had we delayed altering these articles until April, the chances are that you would not probably have had a dividend before May. In this way you will probably have a dividend in the next fourteen days. I may say in passing that I hope by the time I have the pleasure of addressing you in May we shall have the pleasure of announcing that in Egypt we have established another company on a very satisfactory basis. Alexandria, even since I last addressed you, has advanced in such an encouraging way that I think we may look forward to a very good Exchange being established there. The Government have taken it up, and I think when Alexandria has been reorganised and rebuilt we may look for a very satisfactory state of affairs there. In other parts we have taken up—Singapore, and so on—they are all progressing very much as I stated when I last addressed you. I regret the necessity of your attendance to-day, and that you should have been put to the trouble of coming, but different solicitors have different ways of dealing with Articles of Association. I thought the directors had the power of declaring interim meetings. The article in which I thought we had

Digitized by Google

that right says "dividend or dividends," and I thought "or dividends" meant that we could pay interim dividends. The lawyers, however, differ, and we, therefore, thought it better that you should be called together, so that there might be no doubt on the subject. That closes the business of the meeting, gentlemen.

The meeting then separated.

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION (LIMITED).

The ordinary general meeting of this Company was held at the City Terminus Hotel on the 23rd inst., under the presidency of Sir H. W. Tyler, M.P.

The SECRETARY (Mr. Wm. J. Cordner) having read the notice convening the meeting, the report, of which an abstract has appeared in the *Electrician*, was taken as read.

The CHAIRMAN, in moving its adoption, stated that their last meeting was held on August 2 last year, and it was a very miserable one. The directors then called the shareholders together in order, with their permission, to pay a very large dividend, and they felt that the circumstances of the Company were not very likely to contribute to the pleasure of the directors, because there had been before that time a mania for speculation, and every one occupying the position filled by the directors knew that after such a mania, and after the shares had been run up to such a price as this Company's had been, there must naturally come some reaction and disappointment. That reaction had been even more severe than one had imagined, and there must have been very serious and great disappointment among those who purchased shares in the Company at the very high prices they were run up to. On the present occasion the task of the directors was more congenial ["oh"], because they had to reply to the accusations which had been so freely launched against them; and their duty now was not to counsel investors, but to uphold the credit of the Company before the world. Passing to the report and balance-sheet, he called attention to the list showing the expenses, commissions, charges, &c., for the year 1882, as to which one of the charges most freely launched against them had reference. The first item was the salaries account £35,868, including the directors' fees, £25,896. Well, that was a large sum, but it was only what they were authorised to receive by the Articles of Association in proportion to the dividend paid to the shareholders; and he only wished, for their sake, they could that day declare another 100 per cent. dividend, when the directors would be entitled to similar large commissions. He had no doubt that if the directors could have foreseen the grave reaction which had since taken place they would not have taken the fees which they took last autumn. They would not draw their fees for the present half year, and he had suggested to his colleagues that they should draw no further fees until they had paid a dividend of at least 10 per cent. to the shareholders. As regarded the miscellaneous charges, £2,740 had been incurred on account of experiments in the manufacture of carbons, for at one time they had found very great difficulty in getting suitable carbons. It included what they had paid for gas and water, office charges, &c. Coal account, £1,543, was not very heavy, considering the very large works going on at their three large establishments. Carriage account, £3,674, seemed a large sum, but that was on account of their apparatus and machinery carried to and from all parts of the world; and a very large portion of it was charged to the carbons, which they received from Cleveland, America. The law charges might seem heavy—£3,763, but not much more than half of that was for law charges proper, a good deal having been paid in fees to counsel and in retainers to scientific witnesses. They had, however, been threatened with actions, and an action was pending against them by the Gramme Company, who claimed that the Brush machine was an infringement of the Gramme patent. They had no doubt they would defend the Company successfully in that action. The rates and taxes, £2,860, they could not help. Continental and travelling expenses seemed heavy, but they had been obliged to employ gentlemen travelling about the continent continually in connection with their concessions; and to make the patents valid on different parts of the continent they were obliged to manufacture the apparatus in the different capitals. The Crystal Palace Exhibition had cost them £4,869. He did not think any of them would consider that the money of the Company had been spent wastefully at the Crystal Palace Exhibition. They had thought that, if done at all, it ought to be done creditably, and it had been, and had done the Company good. As to the lighting contract account it had been said that the Company had lost £1,596 in the year there, but those who made that statement forgot that that amount represented only the charges in connection with these contracts, forgetting to put the receipts from the contracts against the charges. The last item was £39,791, "commissions and special discounts on sales to licensee companies, as per agreements." They had thought that that was pretty fairly stated, but they had been told that it was a dreadful item, and that there must be a great deal of jobbery in it. It was, however, made up of discounts on sales of apparatus to the sub-companies, on whose purchases they allowed a discount of 20 per cent., and in some special cases even more. Altogether there was a total of £102,832 for all their expenses, commissions, and charges for the year. In a note they stated that they divided that sum into two, because there were separate charges. Of the total amount £58,029 was charged to the statement showing the amount realised from the sale of concessions, and the balance was charged on the other side of the balance sheet to manufacturing account. As regarded the balance-sheet the great feature was the value of their property, and the value of the stocks now in their possession. The value of the property, including the plant at their Victoria, Borough-road, and Portpool-lane works was £66,491, and the value of the stocks at these different works was £93,034, making together in round figures £160,000. That was a large amount, but in the last half of last year there was a very great demand on them, and they had to increase their previously existing manufactures, and to get additional premises to enable them to do so. They had now got in their factories as fine a set of machinery as they would wish to see anywhere, and they had the very large amount of stock he had mentioned. He supposed they would all agree that the electric light was coming into fresh play again when the Act came into force, and then the companies working with them would send in their orders. If it had not been for the sudden stoppage of the sale of their apparatus they would, he said, have been able to declare a very handsome dividend that day. As to their plant, if the electric light were to stop their plant was valuable for manufacture of every description. He did not think that what had been done would be other than beneficial to the Company. There was an item of £50,000 due from Mr. Lane-Fox, which he had undertaken to pay them by March. They proposed to write off 10 per cent. for depreciation of plant and buildings, and £132,950 off the purchase price of the patents—a sum representing the amount they held in shares. Some of these shares might not possess much value, but others they believed to be very valuable. That would be the best way to deal with these shares, as to carry forward the amount they represented would make the balance carried forward look so very large. The original shareholders, too, had no reason to be dissatisfied, as they had had all their money back and something beyond. Let them look at what the Company had done. The Company had been in existence only two years. Out of the first year's work they were able to divide out of manufacturing profits 12½ per cent., and to set aside £90,000 to reserve. In the course of the next half year the great speculation sprang up, and every one went in for electric lighting shares. The directors at one time were almost "torn to pieces" by people who insisted on buying concessions from them in every part of the world. They did the best they could under the circumstances, and the result was the distribution of 100 per cent. dividend to the shareholders. They thought they did right in making the distribution, but they were now told that, having regard to the present position of the Company, they ought not to have distributed so large an amount among the shareholders, and a great many reasons—some of them not very complimentary—had been assigned for their doing so. As to their reasons for doing so, in the first place they were glad to be in a position to pay back to every gentlemen whatever he had invested in the Company; but the real reason why they were anxious to distribute the money was this: The £4 shareholders were the most numerous in the Company, and had the voting power, and the directors had been very seriously threatened that they would be forced into making a call on those shares, which were at a very high premium. If the directors had been forced to call up £6 on them, the shares would have been worth something like £60, and a very large premium would have been realised on the amount so called up. In order, therefore, that there might be no further dissension between the £10 and the £4 shareholders, the directors decided to divide all or nearly all the money they had in hand. The threat of forcing them to make a call was a very serious danger, and they decided to avert it. Since then, unfortunately, the directors had been obliged to make a call, as they found orders did not come in. They had very large manufacturing establishments and a very large and increasing stock, which did not go off. For these reasons they had had to make a call, and now the very persons who before so anxiously desired that a call might be made were the first to cry out against it. Well, now, having gone through all this, let them start afresh, and he believed there was a very good future for the Corporation, with their magnificent stock all ready to turn into money as soon as the tide turned again in favour of electric lighting. After referring to the attacks made on them by certain sections of the Press, he observed that it had been stated that the Company was subject to a great deal of litigation, and that they would have to give up in litigation all that they had swallowed. He was, however, happy to inform them that there was no litigation in which they were engaged which need give them any concern. A very troublesome matter which had cropped up was a mistake which had occurred in the prospectuses of some of the sub-companies. A great many statements had been made on the subject, to which they had paid little attention, and they had felt a delicacy in dealing with it, not wishing to make the difficulties of those who had fallen into the mistake any harder than they were. The present, however, was the opportunity for him to state the exact position of the Company in the matter. They had sold the Brush concession for various parts of the United Kingdom, and, at the same time, they sold, or rather gave away the license for the Lane-Fox lamp. Mr. Lane-Fox, before he came to this Company, had dealt with the British Electric Light Company, and, not finding his dealings with them satisfactory, he paid that company a considerable sum of money to get back his patents, allowing the British Company, however, to use his lamp without his name. Then Mr. Lane-Fox came to deal with this Company, and they made an arrangement with him paying him a certain number of shares, and arranging to pay him a proportion of the profits of manufacture, and half the profits on the sale of the foreign patents. When, however, they came to deal with the patents for the Lane-Fox lamp in this country, they did not feel themselves justified in selling the Lane-Fox licenses, because they felt that they were not exclusive. They sold the Brush patents for a certain sum of money for different parts of the United Kingdom, but they gave the license for the Lane-Fox lamp without any payment whatever. Unfortunately, when some of the prospectuses were issued of the sub-companies, and they were got out in a great hurry, the word "exclusive" slipped into them as applied to the Lane-Fox license. How it did so it was not for him to explain. They knew nothing of it till the matter was made public, when a great fuss was made about it. They, however, had nothing to do with it. At the present meeting there were certain dissensions—two classes. A circular had been sent round, signed by Messrs. Gillitt, Pigott, and Noel, and Mr. Lane-Fox had also been very active. The directors had already had some negotiations with Mr. Gillitt and two other gentlemen—Messrs. Delamere and Bedford, whom they had requested to nominate a director. The directors wanted to get some large shareholder in the concern with them. Mr. Lane-Fox was in quite a different category. That gentleman ought to be working with them as one of them, and not against them, but knowing that the Company was subject to some attack at that meeting he had been preparing to take advantage of the position. He had contracted—the arrangement was not the seeking of the directors—to pay the Company £50,000 next March, buying back a certain portion of his license, leaving the Company, however, with all that would be necessary for their purposes. Finding that this was a little onerous, Mr. Lane-Fox had come to the directors and had asked them to set off what little matters might be in account in his favour with the Company against this £50,000, and he had told them that he should make matters very disagreeable if they did not do so. They had declined his proposal, and the result was a letter which had been freely published in a great many newspapers. After quoting from this letter, he stated that the present instance was the first he had known of a gentleman who was working with, and had com-

Digitized by Google

plicated transactions with a company, taking advantage of a time of attack to serve his own private interests. The directors, however, were not the men to shrink from a difficult position. He concluded by moving the adoption of the report and balance-sheet.

The VICE-CHAIRMAN (Mr. J. S. Sellon), in seconding the motion, said there was no doubt that the true policy to pursue was for all interested in the Company to pull together in unison. His impression was that it would be as much use to try and stay the wind as to stop the future of electric lighting. Persistent statements had been made to the effect that the patents of the Company were worthless. He, on the contrary, did not hesitate to assert that they possessed some of the most valuable and most comprehensive electric light patents that existed. He would go so far as to express his firm belief that in the Brush patent they had the foundation of all successful and economical electric lighting; also that the patents were not only unassailable, but that the principles which were effectually protected under them were so essential to the success of electric lighting that no system which did not embrace them could hope for success. He then referred to the futility of the efforts so far made to supersede the Brush patent; and as to the durability of the Brush machine, the work had been carried on in the City for the last two years by one machine on which not 5s. had been spent for repairs. He looked forward to the time when lighting, heating, motion, and metallurgical operations would be carried out by the aid of electricity. He explained his reasons for his prejudice against alternating current machines, and added that he had no fear of their competition. He maintained that, in low tension machines, the Brush could successfully compete with any other, and that, in those of high tension, which were alone suitable for long range work, they had practically no competitor.

Mr. GILLITT expressed the disappointment he had felt on looking at the accounts. They could not disguise from themselves that there had been a wide-spread feeling of dissatisfaction, suspicion, and distrust with regard to the Company, and he should not be satisfied without a committee of inquiry. He referred to the principles enunciated by the chairman at former meetings, and maintained that they had not been borne out subsequently. What he wanted to see now was the real position of the Company, and it was that which he believed would tend to dispel all the feeling of distrust which had been engendered. He might state that all the gentlemen with whom he had been connected were largely interested in the Company, and were strongly in favour of electric lighting, more especially the Brush system. The whole success of electric lighting was, he believed, largely dependent on the public opinion of the country, and they must therefore remove all doubt. He moved as an amendment "That a committee of shareholders be appointed to consider and report on the affairs, position, and general conduct of the Corporation."

Mr. ROBERT ALSOP seconded the amendment.

Mr. LANE-FOX stated that if the amendment were accepted he would defer any remarks he might have to make.

The CHAIRMAN: Mr. Lane-Fox may proceed with his statement.

Mr. LANE-FOX proceeded at some length to criticise the policy of the directors. After strongly repudiating the statement of the chairman that he was now taking advantage of the present position of affairs to serve his own purposes, he stated that it was at Mr. Sellon's solicitation that he first joined the Company. They paid him £5,000 in shares of the Company, with which he took a liability of £7,500, and just previously to that he had paid £5,000 cash to the British Electric Light Company to sever his connection with them. His license to that company was inalienable, and they were not to use his name. The chairman had stated that he ought to be co-operating with the Company. He had repeatedly, in writing too, offered to assist them in every way, but his offers had been repelled. On one occasion he attended a Board meeting to protest against the way they were proceeding, and he was then told by Sir Henry Tyler that they did not believe in incandescent lighting, that it was impracticable, and that the money which had been spent on it was being wasted. That was the opinion of the chairman, but he (Mr. Lane-Fox) was convinced that incandescent lighting was likely to be the most important branch of the business in the future. As to his financial relations with the Company, some of them might suppose that he had made large sums out of the Company. If he were quietly to accept the directors' statement of accounts he should be a loser of £40,000, notwithstanding that he was entitled to half the profits on the foreign concessions, and 25 per cent. of the profits on the English. He maintained that it had been chiefly in virtue of his name that the sub-companies had been floated. Some of the directors had joined the sub-companies, and in their prospectuses his inventions were stated to be most valuable. The directors had, however, told him they had received nothing from those companies for his licenses, and that therefore his share was nothing. When he saw that very little good was being done by the directors with his patents, he agreed to take them back for £50,000, a sum which he considered was far more than covered by the amount owing to him. About three months ago he was preparing a legal action to be brought against them, but when he discovered their deplorable condition, and that the boasted sums that they had in hand did not exist, he felt that he should do no good to them by bringing the action: and he therefore had offered the directors a compromise. His chief object, however, in addressing them that day was to maintain that the continuation of the present policy of the Board would be utter ruin, and he urged them to take advantage of the opportunity to prevent the disaster which would otherwise come. Contrary to what the chairman had stated there was now an enormous demand for electric lighting, which was likely to be far greater in the future; and so far from the Electric Lighting Act being prejudicial to the Company, as the directors had intimated in the report, it was of enormous assistance to them. They must turn their attention to legitimate work, and if they would know more about the matter he would advise them to read the article on "Wholesale Electricity" in *The Times* of the previous day (last Monday). Let them turn their attention to the class of work indicated in that article, and he believed there would be a grand future before them.

Mr. Alderman WHITEHEAD, in a speech of some length, imputed no want of integrity among the directors, but want of judgment in the best interests of the Corporation. He dealt fully with and criticised various items in the accounts, and stated that he made out that the real tangible securities of the Company represented £302,268, and that instead of a surplus of £109,368, they had a deficiency of £56,311. He supported the proposal for the committee, and stated that it was within his own knowledge that for five months at least the sub-companies had been trying to get from the Company dynamos suitable for incandescent lighting. So hopeless had the Board become in the matter that they had at last agreed that the dynamo of another inventor might be used by the sub-companies.

The CHAIRMAN: That is not true.

Mr. OFFOR, who said he was the manager of two sub-companies, stated that the experience of his companies was that the most important branch of their business would consist of incandescent lighting, and they had also arrived at the conclusion that incandescent lighting was practically impossible without a storage system. He must endorse the remarks which had been made as to their inability to obtain from the Brush Company a machine which would enable them to go on and bridge over the short time before the granting of the provisional orders.

Mr. WM. ABBOTT stated that if anything would have induced him to support the amendment it would have been the moderate tone in which it was brought forward by Mr. Gillitt, but his experience was adverse to committees of investigation, and it was decidedly so on the present occasion.

Mr. DASHWOOD supported the amendment.

A SHAREHOLDER, whose name did not transpire, also supported the amendment, and observed that when the Hudson's Bay Company disposed of land, the money so obtained was distributed among the shareholders as return of capital. If the directors had treated the sale of the concessions in the same way they would not have been able to take for themselves the £25,896 which they had had in fees.

Mr. T. SUTHERLAND agreed in condemning the financial management of the Company, but he was strongly opposed to the appointment of a committee. The effect of that might be that the directors would resign, and the affairs of the Company would come into the hands of men ignorant, perhaps, of the business which was to be conducted.

Mr. PHELPS pointed out that the object was not to turn the Board out.

The CHAIRMAN, in reply, at the close of the discussion stated that in virtue of what he held in the previous company he held a number of shares in this Company. He had sold them, wanting the money for other purposes, and had sold them at comparatively low prices. Had he held for high prices he should have been £30,000 richer than he was. Independently of that, he had never bought or sold a share in any electric light or storage company. As to the serious question raised by Alderman Whitehead as to their inability to supply machines for incandescent lighting, and that his (Alderman Whitehead's) company had used another machine of another company to light some place in the metropolis, he (the chairman) had made some inquiries into the matter, and had found that the Metropolitan Company as a special favour had been allowed to use one of Siemens's machines to light Willis's Rooms with the Swan lamp, and he had been informed that it had broken down twice in the course of the evening. There was no disguising the fact that their balance at the bank had been largely overdrawn. If not they would not have made the call. Mr. Lane-Fox had stated that they had never provided for incandescent lighting. He was surprised at such a statement. The shareholders had no idea of the exertions they had been making to improve and perfect incandescent machines for incandescent lighting, and they had been grieved beyond measure that more progress had not been made. That, however, was through their having trusted Mr. Lane-Fox too much at the Portpool-lane factory. A man had been placed there by Mr. Lane-Fox, who had himself eventually admitted that he could stand him no longer. As to his having said that he did not believe in the incandescent lighting, he had always had the greatest admiration for it, but what he had always said was that it was very difficult to make incandescent lighting pay. With regard to a committee, they were free to look into the books of the Company and into the affairs of the Company generally if it were to the interest of the Company; but the directors would decline to consent to a committee of investigation which would afterwards make a report, and so expose to rival companies, and to the world in general, all the Company's trading accounts. If the committee were carried against them they would be happy to resign their positions. He then put the amendment, and declared that 86 had voted for it. Having put it to the contrary he announced, amid hisses, that it was not carried.

SEVERAL SHAREHOLDERS: "Give the numbers."

The CHAIRMAN: It has been suggested to me that the meeting did not know on what they were voting ["Give us the numbers."]. He made them 86 for and 60 against the amendment. They would put the amendment again [no, no].

Mr. GILLITT said that the ruling of the chairman was entirely wrong. He had stated that the numbers were 86 for and 60 against the amendment. How, therefore, could he say that the amendment was not carried? He must declare in accordance with the show of hands.

The CHAIRMAN stated that he had been guided by the solicitor's advice. He ultimately declared the amendment carried.

A poll was then demanded on behalf of the directors, and it was arranged to take it that day week (next Tuesday) at the City Terminus Hotel between two and five o'clock.

The proceedings then terminated.

YORKSHIRE BRUSH ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of this Company was held at the Cannon-street Hotel, on the 19th inst., "for the purpose of considering an offer for the repurchase from this Company of the Lane-Fox license, for the sum of £35,000, payable in fully paid-up shares of this Company, and, if then considered desirable, passing resolutions authorising the Board of this Company to carry out a sale of the said license upon the above terms, or such other terms as the meeting may decide." Mr. H. W. Lowe presided.

The secretary, Mr. GEO. L. MORTON, having read the notice convening the meeting,

The CHAIRMAN said: When I last addressed you I mentioned that the directors would take the opportunity of doing the utmost in their power to bring about a fair settlement of this question of the Lane-Fox patents. Since that time they have been very actively engaged in trying to make

Digitized by Google

terms for this purpose. I need not tell you that this has occupied a long time, and that it has been a very wearying, anxious time for us to bring this matter to a settlement. We had many conflicting actions going on at the same time, which occupied our time also to a great extent. However, we pushed persistently on with the object of bringing this matter to some settlement, and so soon as we obtained what appeared to us a reasonable proposal we immediately decided to submit it to the consideration and discussion of a general meeting, in accordance with the promise I made at the last meeting that we would not make any final arrangement unless with your sanction and approval. In the circular which you received accompanping the notice calling this meeting we have told you the terms proposed, and at the same time we took the opportunity of inviting those shareholders who would not be able to be present here to give us their views so as to enable us to obtain some idea of their opinion. The concensus of these opinions is this—that the amount of the proposal is considered fair and reasonable within certain limits, but they one and all mention that it is considered highly essential that it should be accompanied by a money payment. The directors themselves have also been very much impressed with this idea from the beginning, and we have held it well in view in our negotiations, but they have been unable to obtain a proposal of a cash payment included in that of the transfer or cancellation of the shares. We can discuss the matter to-day, and whatever you decide on we shall try and carry out to the fullest possible extent. If any shareholder will favour us with his special views on the matter now before us we shall be glad.

Mr. C. PERRY WHITELEY requested that the original letter containing the offer might be read.

The CHAIRMAN: We have not brought with us the original letter. The offer was made on behalf of the Electrical Works Company to buy back the Lane-Fox license in consideration of the sum of £35,000 in paid-up shares in this Company. The letter was the result of all the negotiations that had been going on before, put in a definite shape. Replying to further questions he stated that the terms of the prospectus were carried out as to the vendors, who received £50,000 in cash and £50,000 in paid-up shares. That included the Brush and the Lane-Fox licenses—everything. They paid nothing specifically for the Lane-Fox license. The exclusive right of the Company to use the Brush dynamo was never disputed; but, because the two were lumped together, and the exclusive right was given as to the Brush dynamo, it was assumed that the Lane-Fox license was also exclusive. The practical value of the Lane-Fox lamp was *nil*, as, by the Electric Lighting Act of last Session, any consumer could demand to be supplied with any lamp he chose. If, however, they retained the Lane-Fox license they might lose business, as, by their concession, they were bound to supply the Lane-Fox lamp solely. The offer under consideration had been made on behalf of the Electrical Works Company, who were the nominal parties to whom the Company had to look, but the real parties were the Hammond Company.

Mr. WHITELEY intimated that he should object to the offer as being totally illegal, for the reason that the Electrical Works Company were in liquidation and could not make such an offer. He was very glad to hear that the real parties the Company had to deal with were the Hammond Company. He then referred to the petition he had presented for winding up this Company, and afterwards read the affidavit of Mr. Brown, observing that, if the statement it contained were true, the Company actually did possess an exclusive license to the Lane-Fox incandescent lamp, in which case his petition would fall to the ground, and there would be an end of the matter. If, however, the affidavit were true, why was this offer to the Company continued? Why was it not withdrawn? Why were the vendors so anxious to give them back £35,000? Again, if it were true, what was the effect of the proposal before the meeting? To give up, for a few shares, practically the only thing the Company had got, and for which they gave £100,000. They would then be left solely with the Brush machine, which, from what they had heard from the Hammond Company, was superseded by the Ferranti machine.

Mr. GUEDALLA (of the firm of solicitors who signed the letter containing the offer) stated that Mr. Lane-Fox was prepared to make an affidavit in support of Mr. Brown's. Hence it appeared clear that the Company had acquired the exclusive right to the Lane-Fox lamp. He was prepared to prove that whatever the vendors had received from the Company had been in shares, and that they were absolutely out by £5,000, their deposit in the first instance to the Hammond Company, which had never been returned to them in any form but shares.

The CHAIRMAN stated that that matter was not relevant to the question before the meeting, and that Mr. Guedalla was out of order.

Mr. GUEDALLA, continuing, stated, in reply to the question asked by Mr. Whiteley, that the offer was kept open notwithstanding the statement in the affidavit of Mr. Brown, in order that any difficulty might be got over, the law proceedings abandoned, and that the Company might continue its work.

The CHAIRMAN stated that the transfer of the Lane-Fox license would not prevent the Company from supplying Lane-Fox lamps, as they could get them readily from the Hammond Company, who would gladly supply them as a matter of business. As to the vendors having received no cash, they could not go into matters as between the Electrical Works Company and the Hammond Company. They must go by their records, and they showed that on the 11th July it was resolved that £50,000 in cash be paid to the Electrical Works Company in two cheques of £10,000 and £40,000; and on the 14th July it was resolved that, in accordance with the agreement, the sum of £50,000 and £25,000 fully paid-up shares of the Company be paid to the Hammond Company. As to the progress of the Company, that was continuing in the most satisfactory manner, at Middlesbrough particularly, and at Dewsbury, Huddersfield, and at other places; and they had also made some small installations at Leeds. They had tenders now before them from several important corporations and local bodies, but, of course, the disagreeable position in which they had been placed through the recent action of some of the shareholders had done them considerable harm. The inquiry had been made of them on the part of certain corporations—"What security have we if we give you orders that they will be executed? We hear you are going to be wound up." They were perfectly confident, as they had replied, that they would get the petition dismissed, and the threat of being wound up did not frighten them in the least.

Mr. M'ALISTER observed that the Brush patent appeared to be valueless, and they were asked to part with the Lane-Fox license for £35,000 not in cash, but in shares, and what was their value?

Mr. ROBERT HAMMOND: Holding the intermediate position I do in this matter, you can easily understand my anxiety that I should not take up points which may fairly be called disputed points between the various vendors who were interested in the formation of the Company. There have, however, been two things said here which force me on my feet. I take it that, though the chairman has ruled Mr. Guedalla out of order in raking up this matter of the shares, it is a fair thing to say when it is asked "Why do not these people give us back our cash?" that, as a matter of fact, they invested all the money they got from the Company in the shares of the Company. As a matter of fact, the whole cost of floating the Company and the cash paid to them is represented by shares in this Company. To my mind there is nothing whatever against such a proceeding. They had the option of walking off with £50,000 and spending it or investing it in the shares of the Company; and, if they did invest it in the shares of the Company, who is the loser? As to the allotment on an insufficient subscription, of course I had personally to do with the particular figures connected with the formation of the Company. A figure was agreed on as to which we should go to allotment. I have considered all through that a margin of £25,000 to work the Yorkshire business was amply sufficient. As you know, for some time I conducted on my own resources the business which has been taken over by the Hammond Company, and when that company came out we considered that £40,000 was sufficient capital for the whole of their concessions; and if £40,000 was sufficient to conduct the whole business of the Hammond Company for the whole of their concessions it cannot be considered that £25,000 was too little for the portion of its business in Yorkshire.

Mr. M'ALISTER: Why did you ask for £200,000, then?

Mr. HAMMOND: The amount at which the directors were allowed to go to allotment was £25,000, and they did so. As to the business of the Company, there seems to be a notion that the Hammond Company is antagonistic to the Company. That is quite wrong. The Hammond Company and the Yorkshire Company, to all intents and purposes, as far as interests are concerned, are one, and whatever comes to the Hammond Company, it will be the desire of the Hammond Company to pass on to the Yorkshire Company, and if the Yorkshire Company can use the Ferranti machine—and the first step towards their doing so is, I believe, that they should get rid of the Lane-Fox license—the Yorkshire Company shall be sharers of that machine in their district. While matters are *sub judice* between us and the Brush Company it is rather difficult to speak with entire freedom; but your directors know quite well my friendship for the Yorkshire Company. I was in Yorkshire for three days recently, and all the expenses were paid by myself. Whenever I pass to Middlesbrough I use all my influence for the interests of this Company. I was in Middlesbrough yesterday, and what I was distressed to hear of was that difficulty about the Lane-Fox lamp. Up and down the country there was that difficulty, which I look on as no difficulty, when you are working to spread the use of the light. The Hammond Company have said this. Out of the shares we hold, and being by far the largest shareholders in this Company—and we now possess all that we took at £2—we will give so many of them, being by far the most interested parties in the progress of the Company, in order that all these difficulties may be got rid of. Let us suppose Mr. Brown's statement right, and that there is no difficulty as to this Lane-Fox lamp. In that case Mr. Whiteley asks us, "Why do you give away these shares?" Well, what we feel is this, that whoever is right in the matter, the best thing for the Company is to push on its business untrammeled by legal difficulties. A profitable contract has been put before the Leeds authorities by your Company for £11,000. I am perfectly certain on the figures that that order must come to this Company, and if it does not it will be on account of the legal proceedings. The Leeds authorities are talking of giving orders for £50,000 of work gradually, and I feel that the man who gets their first order, and executes it well, will possibly get the whole order. Mr. Ferranti and Mr. Ince, too, were at Leeds the day before yesterday. Mr. Ferranti will be in Leeds next week; and will help in every way to get this first order from the authorities for this Company. That order, however, is liable to go past your Company, because we do not know how we stand as to the Lane-Fox difficulty. Can you not, therefore, understand that we (the Hammond Company), the largest shareholders in your Company, should say that to make our shares more valuable than they are to-day we will sacrifice a certain portion of them? We still have a large portion. We have made this proposal to the Electrical Works Company, so that they might pass it on to you, and the effect of that offer is that we shall settle down to a good business. In spite of the value of the London market, I am more and more convinced of the future of electric lighting. During the past few days I have been away from London, where one's view of the manufacturing interests of this country is somewhat curtailed. During the few days I have been among the manufacturing districts of the north I have seen more and more the boon which electric lighting is going to be to the workpeople of England. I have been, in fact, where people work with gas from four in the morning till twelve at night, and I have been told that as much as 50s. per gaslight has been paid. We can give at this moment a light which does not rob the air of its oxygen, a light of the same or greater brilliancy, just as manageable and one which the workpeople can bring near the thread of their machines without any danger of fire. Mr. Samuel Morley, when he walked with me through Messrs. Copestake's workshops, was astonished at the progress of the incandescent light. As to your Brush patent, the Ferranti machine has been described as better than the Brush, and as practically making the Brush machine obsolete. The great weakness which we, who have been working for the Brush Company in every part of the country have had before us, is the absence of an incandescent machine. We have wanted an incandescent machine of large extent—not one to run 50 or 100 lights. It is of no use to go into a manufactory where there are 5,000 gas jets going, and to say to the proprietor that we have an incandescent machine which will run 80 lights. What we want to be able to offer is a machine which will run 500, 1,000, or 5,000 lights, and under the Ferranti machine that is possible. In all I have said publicly on the Brush machine I have not spoken against it as an arc machine. As an arc machine you are at present using the Brush machine, and you will probably continue to use it. Mr. Ferranti's arc machine may prove as startling in its day as his incandescent machine, but the thing we have before us is the incandescent machine, which does not, for the moment, interfere with the Brush. A day may

Digitized by Google

come, however, when that will be obsolete; and the Hammond Company, who have the sole right to use the Ferranti machine throughout Great Britain, are the largest shareholders in your Company. What will be the effect of that? We shall want agents, and in our own interest the Yorkshire Company will have all that the Hammond Company can give it.

Mr. H. W. MAYNARD (a director) then moved a resolution (after expressing his faith in the value of the Brush patent), in effect consenting to transfer to the vendors the Lane Fox license for £30,000 in shares, and £5,000 in cash.

Mr. HASTINGS seconded the motion.

Mr. WHITELEY inquired who would pay the £5,000.

Mr. GUEDALLA replied that the offer was simply before them to be rejected or accepted. It was no use losing time, and he told them distinctly that no modification or alteration would be made in the offer.

Mr. STOBART moved an amendment accepting the offer in the terms proposed.

Mr. INCE seconded it, and alluded to his recent visit to Middlesbrough. From personal observation he spoke in very hopeful terms of the prospects of the Company.

The CHAIRMAN put the amendment, and declared it carried unanimously.

A vote of thanks to the chairman and directors brought the proceedings to a close.

LANCASHIRE MAXIM-WESTON ELECTRIC COMPANY (LIMITED).

The statutory meeting of this Company was held at the offices, 56, New Broad-street, on the 18th inst., Lord Delawarr in the chair.

The CHAIRMAN expressed his satisfaction at having to report that the progress of this Company since its formation and the success which had attended all its lighting operations had been all that could be desired, and with regard to the amount of contracts executed, he was advised that they had exceeded those of any other company within the same period. He had no doubt that the amount of actual and profitable work obtained would continue to increase satisfactorily. He would now call upon Mr. Watt, who had formed the Company, and to whom it owed its present successful position, to give an account of its working and prospects.

Mr. HUGH WATT (managing director), in the course of his observations, said: Before entering upon an account of our operations since the formation of this Company, about the end of October last, as a number of the shareholders of this Company are also largely interested in the parent Company, I wish, with your permission, to enter into one or two matters of interest to both companies with regard to the patents held by the parent company and those conceded to this Company for the districts of Lancashire and North Wales. After referring to the change in the name of the parent company, he observed that they had no occasion to abandon the Lontin and Rapieff systems from any defects in them as arc lights. This course had, however, been taken, owing to the necessity, which shortly became apparent, of possessing an incandescent lamp. With the Maxim lamp and dynamo, and the Weston dynamo and arc lamp, the parent company had become the possessors of three complete electrical systems. Continuing, he said: The two first-named systems being among the earliest patents extant, I may state in passing that, as soon as the statement of claims of certain alleged recent inventions is published, the inventors will have to settle with us, in the first place; and, secondly, should we find these machines generate more electricity, and that they are as durable and less costly than those we are now using, we can make them under our patents. In this case the parent company will have no objection to supply the new machines to the Lancashire Company at a percentage against capital, as by the terms of their agreement they are bound to supply the Weston dynamo and lamps and Maxim dynamo and lamps. I will trouble you with a general reference to the grounds on which we claim special merits for our Weston and Maxim dynamos and lamps. The Weston arc system differs from all other systems, not only in the construction of its machinery, but in the character and extent of its current, and the quality, purity, and steadiness of its light. The Weston arc is shorter than that generally used, and the dynamos are constructed to produce a larger continuous current of electromotive force, which is run at a low speed, and this feature af the system accounts for the fact that no accident has ever taken place in any part of the world from this system, although thousands of lamps are now run in America. Even when a large number of lamps is run on the same circuit, the current necessary is not sufficient to injure any person. Every care is also taken at all times to insure the most complete insulation of all parts as a further precaution. The remarkable steadiness of the Weston arc is due to the shortness of the arc, rendering the effect of impurities in the carbons less noticeable than in the long arcs, and further rendering the light a truer sunlight, and more free from bluish or violet tints. The Weston dynamo gives the largest per-centage of electricity, the loss being only about 10 per cent., and the 10-light machine produces rather over 15,000 candle-power, making it, at the price at which it is sold, the cheapest machine in the market. I will now refer shortly to the Maxim system. The incandescent system for private lighting is the most wonderful and perfect yet introduced. Unless on the grounds of economy this system, consisting of a slender carbon conductor burned in vacuum, is superior to the voltaic arc as an absolutely steady and uniform light, and capable of indefinite distribution. Professor Weston has just perfected a shunt-wound Weston, self-regulating and specially wound to suit the Maxim lamps, whereby only the quantity of current necessary for the lamps you choose to burn is generated, thus effecting a great saving in steam-power for the purpose of domestic lighting, where the lights required will necessarily vary as much as from, say, 1,000 to 5,000. This machine acts instantly and spontaneously, so that the light in the lamps left burning does not vary. This is at present the only machine in use which can accomplish this most desirable result. Where it is desirable to vary the illuminating power of the lamps, a regulator can be introduced for this purpose. The Maxim carbon, in the shape of the letter M, thus presenting a fuller and more uniform body of light than any other, is remarkable for its durability and capacity to withstand powerful currents. These lamps have been known to last 3,000 hours, and have been run up to 600 candle-power, which is far in excess of the capabilities of any other incandescent lamp. But our inventors have not been satisfied even with these superlative attainments, and the parent company have just patented an incandescent carbon, which is destined, we think, to supersede our present carbon, being absolutely indestructible. The difficulty to be overcome with regard to an incandescent carbon is chiefly to retain sufficient delicacy and evenness of structure with the highest possible resistance, and in the case of this lamp 3 4,000 ohms resistance has been attained, without the necessity for subsequent treatment. The Maxim and Weston systems, with their ordinary dynamos, regulators, indicators, self-exciting and shunt-wound machines, cut-off boxes, time meters, switches, fusible plugs, single and duplex Weston and Maxim incandescent lamps of various sizes, as well as all future inventions by this eminent electrician for some years to come, is in a position to deal efficiently and economically with public and domestic lighting under every phase and condition. As to the operations of the Lancashire, it is now fully two months since this Company, having been fairly floated, was in a position to undertake lighting. Our centre, in Peter's-lane, Liverpool, had been partly developed by the parent company, and a number of contracts secured, and a second centre taken and some plant put down. In a very few weeks, owing to the success of the lights, we were simply inundated with applications for the light, when, unfortunately, the Corporation stepped in and compelled us to suspend our further operations. The Liverpool council decided to apply to the Board of Trade for a provisional order to supply electric light, but having since rescinded this resolution, and determined to postpone any action in the matter for a year, I was in hopes, as we were the only electric Company who had lit there for any length of time satisfactorily—we have now run several places for a year—that they would grant us a license to execute the contracts offered, but they have not yet seen fit to do so. Had we been allowed to go on, we should now be supplying about 500,000 candle-power of light, at a rental of several thousands per annum, which would have shown a handsome return on the capital employed. The Company has been fortunate in securing as manager Mr. E. H. Thomson, a gentleman of thirty years' electrical experience, and who has been successful in every installation he has fitted up. In Manchester and district we have lit several establishments and mills, and have been in negotiation to lay down a centre similar to that in Peter's-lane, Liverpool. We have also been in treaty, and shown our lights at different places in Lancashire and Wales, and all with best possible results, and are now in negotiation for the sale of a large number of installations. We have not overlooked the lighting of steamers and mines, and are in treaty with all the leading steamship and mine owners.

Mr. WHITWORTH (director) gave an account of operations in Manchester and district, which had been placed under his direct control.

Mr. E. H. THOMSON entered into details as to what had been done since the Company was formed.

Admiral INGLEFIELD (director), in reply to Mr. Brown, said, that having given much attention to the storing of electricity, he was of opinion that accumulators would only become of use in exceptional circumstances, and that the bulk of lighting would continue, as at present, to be done by means of direct supply from convenient centres, as the most economic mode. The parent company, however, had the refusal of one of the latest accumulators, which was considered to be as good as any yet invented.

The meeting closed with a vote of thanks to the chairman and the board.

THE RAILWAY AND ELECTRIC APPLIANCES COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on the 24th inst., at the Cannon-street Hotel, the Duke of Manchester in the chair, "to consider the propriety of approving and, if deemed desirable, to pass a resolution approving and sanctioning a conditional contract, proposed to be dated the 4th day of January, 1883, and to be made between the Company and Messrs. L. Clark, Muirhead, and Co., for the acquisition of their works and premises, situate at Millwall and at Regency-street, Westminster; and of their business, goodwill, plant, and stock-in-trade, upon the terms and subject to the conditions contained in such conditional contract."

Mr. WILLIAM SKINNER (the secretary) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, the object of this meeting is to ask you to sanction—in fact we hoped to be able to ask you to confirm and sanction—an agreement with Messrs. Latimer Clark, Muirhead, and Co., but I am sorry to say that the negotiations have not been completed as to details, and therefore we cannot put before you a definite agreement for your sanction and approval, but what we can state to you I hope will be eminently satisfactory to you. The general grounds upon which we are negotiating you no doubt know. Messrs. Latimer Clark and Company have a great reputation as manufacturers of electric and telegraph appliances, and their names are also well known in scientific circles. On that question I think you can have no doubt whatever. We have a note this morning showing the amount of business they are doing. They have lately put out contracts to the amount of £100,000, and I have no doubt if they get the contracts they will derive a very large profit. They have orders now in hand to the amount of £20,000 or £30,000, and this morning they have had an inquiry for a matter of very considerable amount—some £25,000 of electric and telegraph business—so that we should be, if we joined them, stepping into a very important business. I should state that they have works in Regency-street, Westminster, which I have visited, and they seem to be doing very excellent work. They have acquired very extensive premises at Millwall, where they propose to erect very extensive works. In fact, it would be necessary to have very extensive works to carry out all the business they are anticipating. With regard to the heads of agreement, I had, perhaps, better divide them into two—one, the absolute premises, plant, and stock we take over; and the other, the goodwill of the business. Now, with regard to the premises, plant, and stock, Mr. Worley has investigated the value which we will agree to take them at. We are not bound to take them unless we agree upon the value, and we shall certainly not agree to that unless we see it is to the interest of the Company to make the bargain. All the sum that we pay for that will be a first charge on the profits of the business to the extent of 7 per cent. It is proposed to pay cash for the stock, and to pay a rent for the

Digitized by Google

premises and plant. I believe it is to be paid by quarterly instalments during two years. We shall receive 7 per cent. on all the capital we spend in that way before there is any division between Messrs. Clark and Muirhead and this Company. In payment of the goodwill of their business, we are to give them £10,000 in fully paid-up shares, and two-fifths of the net profits of the business, this Company having the other three-fifths, that is, we get 60 per cent. of the net profits after having withdrawn for ourselves the 7 per cent. In short, we get 60 per cent. of the balance, and Messrs. Clark and Muirhead get 40 per cent. I should say in consequence of our not having definitely settled the agreement we must ask you for discretionary powers to agree to or to modify this agreement, as we see fit. If you have confidence in us as directors I am sure you will consider yourselves safe in our hands. It is as much our interest as yours that we should make a good bargain, and you may depend that if you give us this discretion we shall endeavour to exercise it in the interest of the Company.

Mr. VALLANCE (the solicitor) then read the agreement.

Mr. EDMESTON thought the shareholders should have more information before taking over all the liabilities on Messrs. Clark and Company's contracts, and that they should know what they had done in the past. This Company was established to buy a business for the enormous sum of £95,000, and it had been proved not to be worth a third of the sum. Before taking another business he thought the chairman should tell them something of the success they had already attained. Electric lighting was in that transition state that it might be a very good thing for Messrs. Clark and Co. to get rid of machinery which might have become obsolete.

The CHAIRMAN replied that those were just the matters in question between themselves and Messrs. Latimer Clark and Co., and matters which Mr. Worley was investigating, and which they hoped would have been settled and arranged before this meeting. Mr. Worley had not been able to make out definitely what profits the firm had been earning, because their accounts had not been made up to the 31st December. They had now been made up, and Mr. Worley hoped in a few days to be able to make out what the profits had been, but he was pretty well satisfied that they had been considerable. With regard to the plant and material, that was a matter in discussion between Mr. Worley and Messrs. Latimer Clark and Co. In reference to the contracts, Messrs. Clark and Co. were under an engagement with an Australian Brush Lighting Co., under which they were bound, if necessary, to put up works in Australia. The directors thought that a very uncertain obligation, and, therefore, declined to take over the contract. The other contracts to which allusion had been made were merely orders to furnish manufactured goods, and when they were furnished there was an end to the contract. The goods would be furnished by contract, and the order would not be taken unless there was a good profit, and when those goods were furnished, and the payments made, there was an end to the obligation. Previous to joining the Company, he made inquiries and satisfied himself that everything was satisfactory.

In reply to questions by Colonel JACKSON,

Mr. WORLEY said that all the contracts had been submitted to him, and he could not find anything in them that was at all objectionable. They did not involve, so far as Latimer Clark and Co. were concerned, any liability of a serious character, and the obligations seemed to be, so far as he could see, all on the other side; that was to say that certain persons had undertaken to give them the option of supplying the electrical machinery and apparatus that they required on certain defined terms, and they were to pay for that on delivery, and when delivery was made there was an end of the liability, and under those contracts it seemed to him that the benefit was all on the part of Messrs. Clark and Company. He could not discover in them any liabilities whatever of an extraordinary character. As to the capital required it would be from £20,000 to £30,000. £30,000 would represent the stock, machinery, plant, and working capital, assuming the Company carried on the business on much about the same lines as the vendors had done; but, if the business materially increased, £30,000 would be insufficient. He expected that, in the course of ten days or a fortnight, he should be able to make a definite report as to the profits. With regard to the machinery and plant, the directors had agreed with him that it would be a great mistake to take the whole thing bodily at a valuation. That would mean an unknown quantity, and if there were certain machines which were antiquated they would feel justified in not accepting them. The general basis would be, assuming the machinery to be of the right kind, to take it at actual cost, but if it were old to make a liberal allowance for depreciation. In going into this matter they would not base their calculations upon one balance-sheet but on several.

Mr. SMITH said they had been fortunate in obtaining orders for a considerable amount of work by way of trials from the National Telephone Company for telephone purposes, and only last week he received from the manager of that company the most flattering assurance that, of all the apparatus of the kind he had received up to now, he had received none that worked better than that turned out by this Company. He believed that they would do a large business in furnishing electrical lighting apparatus, and would be able to compete successfully with the Americans, who had hitherto had the monopoly of that business. They had very good friends in one of the railway companies in Scotland, from whom they anticipated receiving orders. They had husbanded well the resources of the Company, and he believed that when the balance-sheet was submitted, the shareholders would be satisfied.

A resolution was then passed giving the directors discretionary power to enter into the proposed arrangement, after which a vote of thanks to the chairman and directors terminated the proceedings.

THE DUBLIN ELECTRIC LIGHT COMPANY.

An extraordinary general meeting of the shareholders of the Dublin Electric Light Company (Limited) was held at the offices of the Company, 37, College green, at twelve o'clock on Monday, the 22nd inst. Mr. Thomas Revington, J.P., chairman of the Company, presided. The following special resolutions, adopted at the meeting of the 4th inst., were unanimously confirmed:—1. "That the Company be wound up voluntarily." 2. "That Robert Gardner, 40 and 41, Dame-street, Dublin, public accountant, be, and he is hereby, appointed liquidator, for the purpose of such winding-up."

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).

Report of the directors for the half year ending 31st December, 1882, to be presented at the twenty-third ordinary general meeting of shareholders to be held on the 31st day of January, 1883:—The directors beg to submit, duly audited, the balance-sheet and accounts for the half year ended 31st December last. It will be seen from these that the gross receipts, including the balance brought from last account, amount to £17,012 6s. 8d., and the gross expenditure, including the half of the annual payment for the new cable, to £6,012 9s. 7d., leaving a sum of £10,999 17s. 1d. to the credit of revenue account. After placing £1,325 to the reserve fund, increasing that fund to £49,500, and providing for the dividend on the preference shares, a balance of £6,674 17s. 1d. remains, out of which the directors recommend the payment of a dividend on the ordinary shares at the rate of 7 per cent. per annum, free of income tax, leaving the sum of £1,074 17s. 1d. to be carried forward to the current half year's account. The cables have continued in good working order, but Mr. Keith, the company's engineer, reports a small fault in the 1875 Cienfuegos-Santiago one, which he recommends should be cut out. An early opportunity will be taken for doing this, the cost of which, it is estimated, will not be great, the fault being near Cienfuegos in shallow water. The Central and South American Company's cables having been completed and opened for traffic, they are now competing with this and the West India Company's lines for Colon and Panama business. A reduction has been made in the tariffs to meet the competition. The directors regret to state that their esteemed colleague, Mr. Thomas Hughes, Q.C., who has been chairman from the formation of the Company, has been compelled to resign his seat at the Board in consequence of his appointment to a County Court judgeship. It has been decided for the present not to fill up the vacancy. The usual comparative statement of traffic is submitted herewith.

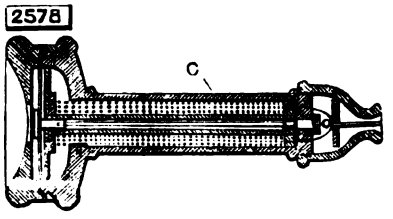
RECENT INVENTIONS.

ABSTRACT OF SPECIFICATIONS.

2578. IMPROVEMENTS IN TELEPHONIC INSTRUMENTS, *S. P. Thompson, Bristol.*—31*st May*, 1882. 6*d*.

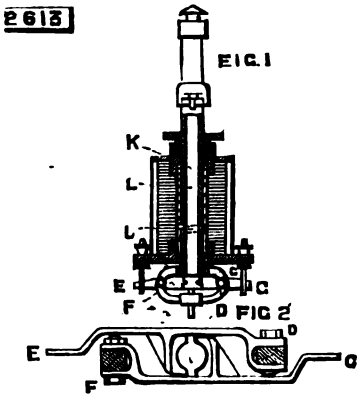
This invention relates to improvements in the receiver of Phillip Reis. One form of the inventor's improvements is shown in the accompanying figure. The action of the instrument illustrated is as follows:—If the current received in the coils C through the line from the transmitter increases in strength, it will change the molecular



condition of the central rod or wire, causing it to elongate slightly if of iron, steel, or cobalt, and if it be nickel, to contract slightly. A decrease in the strength of the current will be followed by a partial demagnetisation of the central rod, producing an inverse movement. Hence, as one end of the rod is tightly screwed up to the case of the instrument, and the other affixed to the tympanum, the varying or fluctuating currents entering the same will cause corresponding vibrations of the tympanum. Other improvements are also described and illustrated.

2613. IMPROVEMENTS IN ELECTRIC LAMPS, *W. E. Ayrton and J. Perry, London.*—3*rd June*, 1882. 6*d*.

This relates to arc lamps. The upper carbon-holder passes through an electro-magnet (see the figure herewith) and carries a frame, C C, with hinges, D F, and levers, D E F G. These levers pass round and clutch the holder. The tube, partly of brass and partly iron, frame, and levers carrying the carbon-holder are hung by spiral springs, J K, from the framing, and in the normal condition of the lamp, when the arc has



been formed, the downward suction of the tube, together with the weight of the movable parts, just balance the upward pull of the springs. The electro-magnet is wound with a coil of considerable resistance, which acts as a shunt to the arc. When the latter gets too long and its resistance increases, more current passes through the magnet, and the carbon falls, thus shortening the arc. It cannot fall far before the two levers come in contact with stops at E and G. This diminishes their grip, and lets the carbon slide independently of the tube and frame C. This is the feeding arrangement. Fig. 2 gives a more detailed view of the gripping levers.

2659. IMPROVEMENTS IN PRIMARY AND SECONDARY BATTERIES, &c., *W. Brain, Cinderford, Gloucestershire.*—6*th June*, 1882. —(*Void.*) 2*d*.

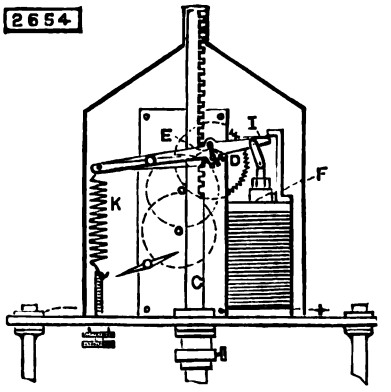
This relates to improvements on the inventor's patent of 30th March, 1882, and consists mainly in subjecting the electrodes and secondary batteries therein described to considerable pressure before or after charging.

2760. POSTS OR SUPPORTS FOR TELEGRAPH WIRES, &c., *H. H. Lake, London.*—12*th June*, 1882.—(*A communication from J. G. Richard, Paris.*)—(*Not proceeded with.*) 2*d*.

This relates to the means of preservation, and it consists in isolating the foot or base of the post from the ground and destructive elements by enclosing the part of the said post which is susceptible of being attached by the humidity of the earth in an impermeable box, cylinder, base, or block.

2654. AN IMPROVED ELECTRIC LAMP, *R. J. Hatton, Stratford, and A. L. Paul, Kensington.*—6*th June*, 1882. 6*d*.

The action of the inventor's lamp will be understood on reference to the accompanying illustration. When the current is switched on, plunger F is drawn into the solenoids, drawing down one end of lever E, and causing spring pawl



I to engage and give motion to ratchet wheel, D, which motion is transmitted to rack, C, and the upper carbon is lifted so as to form the arc. When the arc becomes too long the action of the solenoid is weakened and spring K overcomes it, disengages I, and the carbon descends until the arc is adjusted to the proper length.

2762. IMPROVEMENTS IN VOLTAIC BATTERIES, *D. G. FitzGerald, Brixton.*—12*th June*, 1882. —(*Not proceeded with.*) 2*d*.

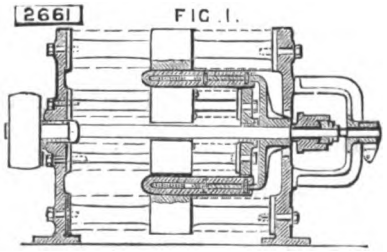
This relates to the employment of peroxide of lead in a strongly compressed condition as the depolarising agent in primary batteries. The positive element may be tin or other metal in a more or less porous condition, and the negative element carbon.

2763. MANUFACTURE OF PEROXIDE OF LEAD, &c. *D. FitzGerald, Brixton.*—12*th June*, 1882.—(*Not proceeded with.*) 2*d*.

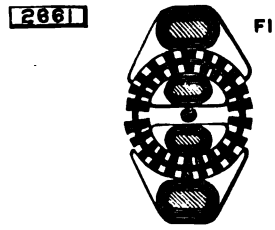
According to one portion of the invention the inventor treats certain salts and insoluble compounds of lead in admixture with an electrolyte, which may be a salt of a metal other than lead, by subjecting them to electrolysis in a tank or in a series of tanks containing suitable electrodes.

2661. IMPROVEMENTS IN APPARATUS FOR PRODUCING ELECTRIC CURRENTS AND IN APPARATUS FOR MEASURING SUCH CURRENTS, *Professor J. Blyth, Glasgow, and D. B. Peebles, Bonnington, Edinburgh.*—7*th June*, 1882. 6*d*.

For the production of currents the inventors employ the machine illustrated in Figs. 1 and 2, which are longitudinal and transverse vertical sections respectively. The machine has a rotating armature consisting of a cylindrical ring of soft iron, having upon it a number of separate coils of insulated wires. Between the coils are iron links, by means of which the armature ring



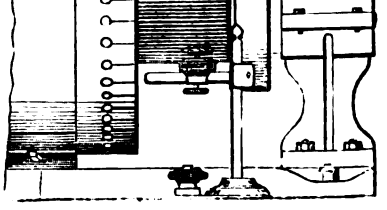
is fixed to one end or edges of a cylinder of iron, which has at its other end a disc or spokes connecting it to a boss fast on the driving shaft. The coils of wire are connected to a commutator. Separate electro-magnetic pole pieces are arranged to act upon the outer and inner sides of the armature ring, and the magnet shanks or bodies of the external pole pieces are excited by coils of insulated wire, which are separate and distinct from similar coils employed to excite the magnet shanks or bodies of the internal pole pieces. Thus a double machine is formed, as currents can be produced with either internal or external



electro-magnets removed. For measuring a current the inventors take a shunt of comparatively great and known resistance from the main circuit by means of two wires which are led to separate electrodes immersed in water in a closed vessel. The shunt current causes electrolysis of the water, and the oxygen or hydrogen, or the two combined, are led through a meter such as is used for measuring illuminating gas. As the production of the gases has a known and definite relation to the current passing through the main circuit, the meter measurement serves as a data for calculating the quantities of the main current.

268,956. DYNAMO-ELECTRIC MACHINE, *Elmer A. Sperry, Cortland, N.Y.*—*Filed* 28*th April*, 1881.

Claim.—(1) In a dynamo-electric machine, a commutator mounted loosely on the armature shaft, its sections retaining their connections with their respective armature coils, in combination with means for automatically adjusting said commutator, as specified. (2) In a dynamo-electric machine, the combination of the flexible conductors with the sections of an adjustable commutator, whereby the electric connections of the sections are retained in all positions, and means, as described, for automatically adjusting the position of said commutator as specified. (3) In a dynamo-electric machine, the centrifugal governor, as described, in combination with the movable commutator and connected with the same, whereby its position is automatically controlled in



response to variations in the speed of rotation of the machine, substantially as specified. (4) The combination, with the movable commutator of a dynamo-electric machine, of a current regulating device, substantially as described, whereby the commutator is caused to move automatically on the shaft, relative to its points of maximum and minimum current, in response to variations in an electric current, substantially as described. (5) In a dynamo-electric machine, the combination with the commutator brush clamps of the supporting springs attached thereto, the free ends of which rest in slots provided in rods, upon which the clamps are loosely mounted, whereby the pressure of the brushes can be adjusted by rotating said rods, substantially as described. (6) In a current-regulating device, the combination of the pawls, links, lever, armature, and spring, with ratchets, substantially as specified.

2740. IMPROVEMENTS IN ELECTRIC LAMPS, &c., *G. Zanni, Hatton-garden.*—10*th June*, 1882.—(*Not proceeded with.*) 2*d*.

This relates to improvements in lamps in which light is produced by the incandescence of a carbon point which is pressed by weight against a block of carbon. Two or more carbon rods are proposed to be substituted for the one hitherto employed, in order to avoid the extinguishing of the light owing to flaws in the single carbon.

SLIP

NEW COMPANY.—The Canadian Electric Light Company has been formed at Montreal.

TELEGRAPH EXTENSION.—The telegraph is to be extended to the village of Hopeman in Elgin county, Scotland.

ROYAL INSTITUTION.—Yesterday (Friday) evening Sir Wm. Thomson, F.R.S., was to lecture on "The Size of Atoms."

Dr. SIEMENS.—The St. Petersburg Academy of Sciences has elected Dr. C. W. Siemens, F.R.S., a corresponding member.

BRITISH INSULITE COMPANY.—A meeting of this company is to be held on Monday next, at the Guildhall Tavern, at 2:30 p.m.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended January 26 amounted to £4,043.

PROF. HELMHOLTZ.—A telegram from Berlin, dated Jan. 30, says that the Emperor has ennobled the celebrated scientist, Professor Helmholtz.

TRANSMISSION OF POWER BY ELECTRICITY.—The first of a series of articles on this subject by Professor O. J. Lodge appeared in last week's *Engineer*.

THE TELEPHONE IN BOMBAY.—The Bombay Telephone Company held its first annual meeting on January 8. There are now 147 subscribers to the exchange.

ELECTRIC LIGHTING IN BRISBANE (QUEENSLAND).—Latest accounts from the colonies say that a very successful trial of the electric light has been made in Brisbane.

ELECTRIC LIGHTING AT STOCKPORT.—The electric light was used for the first time in the police court at Stockport last week. The Pilsen arc lamp was employed.

EASTERN EXTENSION TELEGRAPH COMPANY.—This company notify that the coupons on their Six per Cent. Debentures, due on Feb. 1, will be paid at the Consolidated Bank.

ELECTRIC LIGHTING AT BATH.—The Great Western Electric Light Company have obtained a contract for lighting the extensive premises of the "Merchants' Alliance," 19, Stall-street, Bath.

PROPOSED TELEPHONIC EXCHANGE FOR ABERDEEN.—A scheme is on foot in Aberdeen to start a telephone exchange, which shall work on a cheaper basis than that of the National Telephone Company.

ST. MARYLEBONE.—The Vestry of St. Marylebone intend to oppose provisional orders, but will ask for leave to negotiate with companies for supplying electricity for a limited period under license, in a selected portion of the parish.

RESIGNATIONS.—Sir Charles Bright and Mr. Edward Bright have resigned the positions they have held with the British Electric Light Company, the former as consulting engineer, the latter as a member of the board of directors.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending January 26, 1883, were £2,728, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

GREENWICH.—The Greenwich Board of Works have resolved to write to the Board of Trade stating that they are favourable to the supply of electric light in part of their district, but are opposed to any scheme which proposes to absorb the whole of the district.

SOUTH AFRICAN TELEGRAPHS.—The revenue receipts of Cape Colony from telegraphs during November last were £4,310 4s. 4d., against £5,476 18s. 11d. in the same month of 1881, or a decrease of £1,166 14s. 7d., mainly owing to a reduction in the tariff rates.

ELECTRIC LIGHT FOR SHIPS.—In the Austrian Parliament, at Vienna, on the 26th of January, Herr Rosier addressed an interpellation to the Minister of Commerce in favour of the use of the electric light on railways and ships with a view to the prevention of accidents.

GREAT NORTHERN TELEGRAPH COMPANY.—This company announce the issue of £300,000 five per cent. debentures, with half-yearly coupons attached, payable 1st March and 1st September in each year. Messrs. C. I. Hambro and Son offer the debentures for subscription at £101 for each £100.

THE ROYAL SOCIETY.—At the meeting of this society on Thursday the following papers were to be read, viz.:—Mr. S. Bidwell "On the Electrical Resistance of Carbon Contacts," and Professor D. E. Hughes, F.R.S., "On a Theory of Magnetism, Based upon new Experimental Researches—Preliminary Note."

ELECTRIC LIGHTING FOR WORKSHOPS.—Last week Mr. Andrew Jamieson read a paper before the Institution of Engineers and Shipbuilders at Glasgow on "Electric Lighting for Large Spaces and Workshops." We have no space to refer at length to this paper in our present issue, but shall hope to do so later on.

CHELSEA.—At the last meeting of the Chelsea Vestry the report of the Electric Lighting Committee, which we gave in last week's issue, was adopted, and votes of thanks to Mr. Mossop, chairman, and Mr. G. H. Stayton, surveyor, for their services in connection with the drawing up of the report were unanimously passed.

THE TELEPHONE CASE.—The case of the United Telephone Company *v.* Harrison, Cox-Walker, and Co., had progressed so far during the week that Mr. Aston, Q.C., counsel for the respondents, had commenced his argument on Tuesday last. Up to the time of going to press, however, the result of the case was still unknown.

THE "TARTAR."—The steamship "Tartar" was launched last week at Whiteinch. She has been built for the Union Steamship Company, by Messrs. Aitken and Mansel. Her dimensions are:—Length 392ft., breadth 47ft., depth 33ft. 6in., gross tonnage 4,359. She is magnificently fitted up, and will be lighted by incandescent lamps.

ELECTRIC LIGHTING IN KENTUCKY.—The Brush Company has challenged the United States Electric Light Company to a public test of their systems, in Louisville, Kentucky. The loser, says the *Sanitary Engineer*, is to pay 1,000dols. towards the expenses of the exhibition, and 4,000dols. to the Polytechnic Society of Kentucky.

FIRE ALARMS IN GLASGOW.—The electric street fire alarums placed throughout this city were used 152 times to intimate the outbreak of fires during last year, and in 45 instances were the means of calling out the brigade unnecessarily—15 of which alarms were given with good intent, nine through contact with other wires, and 21 thoughtlessly or mischievously.

PROGRESS.—Five large steamers were last year fitted with electric lights by one of Messrs. Siemens's agents at Manchester. They were—the "Normandie," 400 Swan lamps,

Digitized by Google

and 16 Siemens arc lamps; the "Arizona," 300 Swan lamps; the "Antonio Lopez," 70 Swan lamps; the "Orient," 160 Swan lamps, and 4 arc lamps; and the "Austral," 170 incandescent, and 4 arc lamps.

THUNDERSTORM.—During a thunderstorm in the neighbourhood of Pontypridd on Tuesday, a house, occupied by a tenant-farmer named Evan Williams, was struck three times by the lightning. One flash passed down the chimney stack and knocked down a mantelpiece, another knocked away a portion of the building, and, passing into an outhouse, killed five cows, and a third smashed the bed room window.

FOG SIGNALLING AT SEA.—Mr. W. Langdon, superintendent of the Telegraph Department of the Midland Railway, writes to *The Times*, recommending that steamers, when caught in a fog at sea, should indicate their course to approaching vessels by a system of whistling, based on the Morse alphabet, as used by telegraphists; and he further suggests that this might be done by means of machinery.

PHŒNIX ELECTRIC LIGHT COMPANY.—The *Gazette* of January 26 contains a notice to the effect "that at an extraordinary general meeting of the members of this company at the Cannon Street Hotel, E.C., on the 5th January, the following special resolution was duly passed; and at a subsequent extraordinary general meeting on the 23rd January the following special resolution was duly confirmed:—'That the company be wound up voluntarily.'"

THE TELEPHONE IN INDIA.—At the request of H.E. the Commander-in-Chief, instructions have been issued for putting up, before the next season, telephonic communication between Sir Frederick's usual residence, "Snowdon," at Ootacamund, and the office of the head-quarters, and any other Government departments he may consider necessary, the necessary "exchange" station being the Government Post Office. So says a contemporary.

THE "HAMMONIA."—On Saturday last this vessel, which has been recently built by Messrs. J. and G. Thomson, of Clydebank, Glasgow, for the Hamburg-American Steamship Company, went down the Firth on her trial trip. She is 375ft. long, 45ft. wide, and 34ft. deep. Her gross tonnage is about 5,000. She is fitted with 100 Swan lamps, the current for which is supplied by a Siemens dynamo, driven by a 6 h.-p. (nominal) Tangye engine.

ELECTRIC LIGHTING PLANT FOR TRANSPORT.—An electric lighting plant for a cotton mill in one of the smaller American republics has just been supplied by Messrs. Siemens Brothers to a Manchester firm. It comprises seven arc lamps, 236 Swan incandescent lamps, one dynamo-machine (SD^0) and one alternate current machine (W^2). The whole has been so arranged that it can be put together on the spot by persons without knowledge of electrical apparatus.

SOCIETY OF ARTS.—The following premium is offered by the Society of Arts for the 129th session of the society (1882-3):—Howard Prize: A prize of £100, for the best essay on the Utilisation of Electricity for Motive Power. Preference is to be given to that essay which, besides setting forth the theory of the subject, contains records, with detailed results, of actual working or experiment. The society reserves the right of publishing the prize essay.

METROPOLITAN BOARD OF WORKS.—At the last meeting of this Board Mr. Selway moved "That it be referred to the committee (Works and General Purposes Committee) to prepare and deliver to the Board of Trade objections to the various provisional orders applied for under the Electric Lighting Act, 1882, with such clauses as may secure the Board's right over the Thames Embankments, the bridges, subways, and the sewers of the metropolis," which was adopted.

M. GASTON PLANTE.—This well-known French electrician (the inventor of the secondary battery) has been presented by the Society of Arts of Paris with the Ampère medal for economic arts. We are glad to be able to chronicle this addition to the honours conferred on a man like M. Planté, whose modesty is so great that one rarely sees his name mentioned except by those who remember that the secondary battery of to-day is Gaston Planté's own child in slightly altered garb.

THE TELEPHONE IN CANADA.—The use of the telephone has developed largely in Canada. In 1882 more than 1,000 miles of telephone lines were constructed. Montreal has 866 subscribers, Toronto 525, Ottawa 250, and Quebec 240. Besides these larger centres more than 100 small towns have exchanges, and some of them are connected to one another by telephone lines. The total number of subscribers in the Dominion is about 4,500.—*Bulletin* de la Compagnie Internationale des Telephones.

WIRES IN PHILADELPHIA.—According to an American contemporary, Philadelphia derives an annual revenue of 12,000dols., from telegraph, telephone, and electric light companies, for the use of its overhead and underground wires. Each company makes a return annually of the number of poles, &c., and a payment of 5dols. per annum for each mile of wire used for telegraph or telephone purposes, and 15dols. per mile per annum for electric lighting purposes is required. There are at present about 10,000 miles of wire in the city.

STANDARD WIRE GAUGE.—At a recent meeting of the Wolverhampton Chamber of Commerce it was reported that the council had written to the Board of Trade saying that though the standard wire gauge proposed by that Department was not in every respect such as they would have liked, yet they felt it would fulfil the purposes of a national standard wire gauge. They were so anxious to see a workable gauge introduced that they preferred not to make any suggestions lest they should hinder, or possibly frustrate its adoption.

SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.—The next meeting of this society will be held at 25, Great George-street, on Thursday, February 8, at 8 p.m., when the following papers will be read:—"On the Magnetic Storm of November 17th, 1882," by James Graves, member (communicated by H. Weaver, member); "On a Magnetic Storm in India," by E. O. Walker, member; "On Earth Currents in India," by E. O. Walker, member; "Earth Currents (third paper), Sun Spots, and Electric Storms," by Alex. J. S. Adams, associate.

ELECTRIC COMMUNICATION IN TRAINS.—Sir Edward Watkin's somewhat loose and illogical statement at a recent meeting of the South Eastern Railway Company that, though the company had its trains fitted with electric communicators between passengers and guard, these had not been used once in six months, and, therefore, they were useless and needless, has been severely and rightly criticised by correspondents of the *Daily News*. Their argument is "prevention is better than cure," and that the fact that the communicators had not been used showed how effectual they were.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—An extraordinary general meeting of this company will be held at the offices, 38, Old Broad-street, E.C., on the 6th February, at one p.m., for the purpose of considering and, if thought fit, passing a special resolution approving the Bill now pending in Parliament, intituled "A Bill for re-

Digitized by Google

moving doubts as to and for extending the powers of the Telegraph Construction and Maintenance Company (Limited)," and for other purposes. The principal object of the Bill is to enable the company to carry on the business of constructing and dealing with works and apparatus for electric lighting and other uses to which electricity can be applied.

ANGLO-AMERICAN TELEGRAPH COMPANY.—At a meeting of the board of directors of this company held on the 26th January it was resolved (after placing £37,500 to the credit of the renewal fund for the quarter ending 31st December, 1882) to recommend to the proprietors at the next half-yearly general meeting of the company to be held on the 9th February the declaration of the following dividends, all free of income tax:—(1) A balance dividend of 1 per cent. upon the ordinary consolidated stock for the year ending 31st December, 1882; (2) a balance dividend of 2 per cent. upon the preferred stock for the year ending 31st December, 1882, both payable on 10th February. After paying the foregoing dividends, there will be a balance of about £6,900 to be carried forward to the next account. The above dividends, together with those already paid, will amount to $2\frac{3}{4}$ per cent. on the ordinary consolidated stock and $5\frac{1}{2}$ per cent. on the preferred stock for the year 1882.

ELECTRIC LIGHTING IN ST. MARTIN'S-IN-THE-FIELDS.—The Vestry of St. Martin's-in-the-Fields will oppose all the provisional orders referring to their district on the following grounds:—"That they seek to set aside the provisions of the Electric Lighting Act of 1882, and the rules of the Board of Trade in relation thereto, and to extinguish the right to control the public streets now vested in the local authority; that there is no provision for a regular and efficient supply of electricity, nor for the security of the public against personal injury, inspection by the local authority, or for a reduction in price after the payment of a dividend of, say, 10 per cent; that the companies seek, without obtaining consent of the vestry, power to break up the public streets, to place wires above ground, and to acquire sites for lighting stations." The vestry also consider that no concession to a company should be for more than fourteen years, that the vestry should have power to inspect the company's accounts, and that penalties should be exacted for failure to execute the proposed works within a reasonable time.

THE ANGLO-AMERICAN BRUSH CORPORATION.—We have received a copy of a circular that has been issued by this company, which briefly recapitulates the events which took place at the meeting, reported in our last issue. After reiterating what was then said by the chairman, viz., that they could not accede to the proposition to appoint a committee of shareholders to examine and report on the books and affairs of the corporation, since the report would necessarily be made public, and would injure the corporation by revealing its trade secrets, the circular states, in answer to "allegations freely made at the meeting" above-mentioned, that "the directors have during the past six months been earnestly engaged in, and have now perfected, the manufacture of a new class of economical machines for incandescent lighting, and of apparatus of various descriptions essential to the success of domestic and general electric lighting." The directors conclude by stating that there is a a vacancy at the Board which they will be glad to fill up "if suitable names are suggested to them." We would refer our readers for further information to our reports of meetings.

ELECTRIC LIGHTING IN BERLIN.—A correspondent sends us an account of the lighting of the Berlin Academy of Painting and Sculpture as carried out by the Edison Company. The entrance from the street was lighted by ten lamps fitted on to two lampposts and a chandelier in the form of an imperial crown. The vestibule and stairs were lighted by another chandelier with 32 lamps and two large wall brackets. This is, we believe, the first time that an exhibition of pictures has been opened at night time in Berlin. Our correspondent does not say why, but we are led to infer that the pictures could not be entrusted to the tender mercies of gas. In the picture rooms several more chandeliers were erected, being made to represent flowers of all kinds. These were constructed by Messrs. Kraunne Schäffer, Hauschner, and Spinn. In all 200 A and 100 B lamps were employed, the dynamo machine being driven by one of Messrs. Ruston, Proctor, and Co.'s 16 h.-p. engines. The exhibition was visited by many notabilities, amongst others their Royal Highnesses the Crown Prince and Princess, all of whom were loud in their praise of the lights. Another installation of Edison's system has been made in the factory of Messrs. Rosenfeld and Co., of Cöpnick, sixty lamps being at present in use. The proprietors and *employés* are so pleased with the system that it is in contemplation to extend the number of lamps to 150. Both these installations were carried out by Mr. H. Warde, engineer to the Edison Company.

ELECTRIC LIGHTING FOR WALSALL.—At a meeting of the Walsall (Staffs.) Town Council recently, it was resolved to take all steps necessary to oppose the South Staffordshire and Incandescent Electric Lighting Companies, who had applied for provisional orders for that town. It was also stated that the council, in company with seven other boroughs, had retained Professor Jenkin, to advise them on scientific questions, and that the council proposed to see the insertion in any provisional order that might be made of clauses for the following purposes—viz.:—(1) Requiring the company to satisfy the Board of Trade, before commencing operations, that it has a sufficient amount of capital, and in the case of one company which sought to supply several towns, to allot to Walsall a certain amount of capital for the carrying out of the works; (2) that two companies shall not work on the same area; (3) that the council may have a voice in the selection of a site for the erection of the machine house; (4) that overhead lines shall be prohibited; (5) that all purchasers shall be put upon the same footing as regards price, and that the price for public lights shall be as low as to any other consumer; (6) that adequate powers shall be taken as to commencement and continuation of supply, and especially to prevent the companies suspending the supply two hours each night; (7) that in the case of the profits of the companies being increased by new inventions, or other causes, the public should get the advantage, as in the case of gas companies; (8) that the roads should be broken up only under the direction of the council; (9) that the companies should deposit or guarantee a sufficient sum for the completion of the work, and that the Corporation should have power to purchase at the end of fourteen years.

ELECTRIC LIGHTING IN NEWINGTON.—The Works and Sanitary Committee of the Newington Vestry have drawn up an exhaustive report on the proposed introduction of the electric light into that parish, from which we extract the following:—"The main question arising out of the subject of electric lighting is one of cost, and it is to this question that your committee have devoted considerable attention, with the view of not only assuring the vestry, but themselves individually as ratepayers, whether the adoption of the new illuminant is likely to be of any real benefit to the parish." Referring to an estimate from Messrs. Siemens Brothers to light the

Digitized by Google

parish, the report goes on to state that "this estimate is calculated to displace 200 lamps of an illuminating power of 3,716 candles, and light the streets by 95 lights, of an illuminating power of 28,500 candles. The machinery, &c., necessary to supply electricity to these 95 lights was estimated to cost £8,000, while the maintenance charges reach £2,636 16s. per annum, whereas the cost of gas for the 200 lamps displayed amounts to £834 17s. 4d. per annum. It will be seen, therefore, that even if the vestry took up a loan of £8,000, repayable in fifteen years with interest at 4 per cent., the interest and instalments, together with the maintenance charge of £2,636 16s. for producing an illuminating power of 71,500 candles by electricity, is at least 45 per cent. less than the cost of the same illuminating power by gas. The gas company, if they contemplate deterring the vestry from supplying electricity, must make a considerable reduction in the price of gas, and then, if they do this, the ratepayers, instead of complaining, will have reason to be thankful that an expenditure of £20,000 (whether probable or actual) has been the means of bringing about this result. The interest and instalments on a loan of the sum named amount to a trifle over a penny rate in the pound, so that a person living in a house rated at £35 per annum may have to pay an increased rate of, say, 3s. in the year; but should the price of gas be reduced to only 2s. 6d. per 1,000 cubic feet, he would save 9s. in his gas bill, taking the consumption at 36,000 cubic feet per annum, which appears to be about a fair average for that class of house. In the case of a shopkeeper paying £42 10s. per annum for gas, the result is even more satisfactorily in favour of the ratepayer. For example, if occupying a house on Newington-causeway, he might probably be rated at £290, and his contribution towards the rates on a loan of £20,000 would be £1 4s. 2d. per annum, whereas the saving effected in gas, if only reduced in price 4d. per 1,000 cubic feet, would be £5, so that he would benefit through the action of the vestry to the extent of £3 15s. 10d. a-year. Having determined, therefore, not to advise the vestry to undertake an installation exceeding in first outlay £20,000, your committee have conferred several times with Mr. Shoolbred upon the area which should be included in the compulsory district, and as in determining this question the revenue for private lighting must not be lost sight of, your committee have arrived at the conclusion that the area of compulsory supply should be limited in the first place to the houses abutting on the Walworth-road, between the railway bridge and the New Kent-road, and thence along Newington-causeway to Union-road, and that the whole of the Elephant and Castle block, together with the houses and shops in Newington-butts, from Short-street to Draper-street, should be comprised in this area of supply." After a good deal of discussion the following resolution was adopted by the meeting, to which the above-mentioned report was submitted, viz.:—"That the draft license submitted in this report defining the area of compulsory supply in accordance with the provision of the Electric Lighting Act, 1882, be approved; that the memorial asking for the approval of the Board of Trade thereto be sealed, and that a cheque be drawn in favour of the Board for £50, to be deposited with the memorial in accordance with the rules issued by the Board."

Electrical Resistance of Selenium Cells.—In a paper recently read before the Physical Society, Mr. Shelford Bidwell criticises Dr. Moser's theory as to the effect of light in reducing the resistance of selenium cells. Briefly this theory is as follows:—Selenium reflects the invisible portions of the spectrum, absorbing principally the visible or illuminating rays; the vibrations thus taken up assume the form of heat; and the temperature of the cell is thereby raised. In consequence of this rise of temperature the selenium expands; it is accordingly pressed into closer contact with the electrodes, and, as in the case of the microphone, the resistance of the system is proportionately diminished. On the contrary, when the cell is screened from the light, the absorbed heat is radiated away, the selenium contracts to its original volume, and then its resistance becomes the same as at first. Mr. Bidwell tested this theory as follows:—"If it is true," he says, "that the observed effects are due merely to a rise of temperature, then it is clearly immaterial whether such rise of temperature is brought about by the heating action of light or by the direct application of heat in the ordinary way." Mr. Bidwell warmed some cells over a gas burner, with the following results. We quote from his paper:—"A selenium cell was placed in an air bath in absolute darkness, the bulb of a thermometer being very near its surface. The temperature of the air was 17deg. C., and the resistance of the cell at the beginning of the experiment was 140,000 ohms. The bath was then very slowly heated, and the resistances measured at every degree. At first, the rise was very rapid, then more gradual, until the temperature reached 23deg., when the maximum resistance of 150,000 ohms was attained. With continued heating the resistance fell, slowly at first, then more rapidly, then again slowly, the final measurement at 100deg. being only 16,000 ohms. [Note.—When the cell was removed from the air bath, its resistance in the dark in air at 18deg. was found to have increased to 90,000 ohms.] The same cell was afterwards submitted to the combined action of heat and light. A glass beaker was fitted with a wooden cover, to which the selenium cell was attached so as to hang perpendicularly inside the beaker; the beaker was placed in a sand bath, which was heated by a Bunsen burner, and the cell was illuminated by a powerful paraffin lamp at a distance of 30 centimetres. At 18deg. its resistance was only 19,000 ohms. As in the former case, the first application of heat was accompanied by a rise, though smaller and more gradual than before, the maximum of 24,000 ohms occurring at about 29deg. The fall which followed was also very gradual, the resistance at 100deg. being 10,000 ohms, or only 14,000 less than the maximum, as against a difference of 140,000 in the former experiment. In these experiments it might possibly be suspected that the initial small rise of resistance is due to some accidental disturbing cause, and does not point to any essential characteristic of selenium, or, rather, perhaps, of selenium cells." The following experiment seems, however, to settle the point conclusively:—One of my selenium cells did not at ordinary temperatures exhibit this peculiarity. When heated its resistance at once went down without any preliminary rise. This cell was placed in air at a temperature of 0 deg., and after remaining for half an hour its resistance was found to be 147,000 ohms. The temperature was then slowly raised, and, as I expected, the resistance at first went up, attaining a maximum of 219,000 ohms at 13deg., after which it went down to 134,000 ohms at 36deg., when the experiment was stopped. This particular cell differed from others only in the fact that it acquired its maximum resistance at a temperature slightly below instead of slightly above the average temperature of air. The supposition that light produces its effect by heating is further negatived by the fact that a comparatively high degree of temperature is required to bring down the resistance of the cell to the point to which it is instantly reduced by exposure to a strong light."

ON THE ABSOLUTE MEASUREMENT OF ELECTRICAL RESISTANCE.*

BY PROFESSOR G. CAREY FOSTER, F.R.S.

A paper having the above title was read by Professor Foster at the meeting of the Physical Society on the 27th January. After pointing out the general principles on which the chief experimental methods hitherto employed for the absolute measurement of resistance are based, the author went on to give details of the method proposed by himself in 1874, at the meeting of the British Association in Belfast, and employed in experiments of which the results were communicated to the York Meeting in 1881, and published in *The Electrician* (Vol. VII., pp. 266, 267) for the same year. In this method the electromotive force induced by the earth's magnetism in a circular coil of wire revolving about a vertical diameter is balanced against the difference of potential required to maintain a current of known strength through the conductor whose resistance is to be measured. The absolute value of the electromotive force is known from the dimensions of the spinning coil, its rate of rotation, and the earth's horizontal magnetic force; the strength of the current is deduced from the deflection produced by it in a galvanometer of known dimensions, and from the earth's horizontal force; and the ratio of the electromotive force to the strength of current is the resistance required. The correctness of the results depends essentially upon the accuracy with which the dimensions of the spinning coil and of the absolute galvanometer can be measured. These were ascertained by measuring with a steel tape the circumferences of the brass rings on which the coils were wound, and then measuring again after each layer of wire had been put on. These measurements seemed to indicate that, in the case of the revolving coil, the layers of wire first wound on underwent a slight but perceptible compression by the outer layers, a result which is not surprising when it is considered that the normal pressure towards the axis of the ring, due to the whole coil consisting of 32 layers each containing 30 turns of wire, amounts to about $13\frac{3}{4}$ atmospheres. In the galvanometer coils there was evidence of a very slight effect of the same kind.

The conditions most favourable to sensitiveness were investigated by the late Mr. Charles Hockin, M.A., who showed (1) that the electromotive force of the battery employed to compensate the electromotive force of the coils should be *twice* that of the latter; (2) that the resistance of the spinning coil should greatly exceed that of the battery; (3) that the resistance of the absolute galvanometer should be equal to the resistance to be measured; (4) the resistance of the "zero galvanometer" (that is, the galvanometer used to show when the electromotive force of the coil is accurately adjusted) should equal the resistance of the coil, together with half the resistance to be measured. It was found practicable to make a sufficient approximation to these conditions in the experiments. At the speed of rotation mostly employed, about twelve turns per second, the electromotive force of the coil was very nearly 0·1 volt, and, as the compensating current was produced by a thermopile of electromotive force about 0·22, condition (1) was almost exactly fulfilled. The resistance of the coil being about 50 ohms, and that of the thermopile a small fraction of an ohm, condition (2) was also complied with. The resistances measured were from 70 to 80 ohms, and that of the absolute galvanometer about 60, thus nearly agreeing with condition (3). With the values already given, condition (4) would require the resistance of the zero-galvanometer to be about 90; the galvanometer actually employed had a resistance of 135.

The methods adopted for measuring the arc of contact of the commutator, and for adjusting the centre of the arc to the magnetic meridian, were described. The speed of the revolving coil was given by marks made on a moving strip of paper by a glass pen controlled by a small electro-magnet, the circuit of which was completed for an instant at every hundredth revolution, while seconds were marked on the strip by a similar pen acted on by a clock. The experiments hitherto made were not considered as anything more than trials of the method, but from this point of view they were regarded as satisfactory, the chief points in which improvement is required being the maintaining the speed of the coil sufficiently steady and measuring accurately the speed obtained.

The following table gives the results of the most important determinations of absolute resistance hitherto published. The numbers express the resistance of the B.A. standard of 1863 and 1864, the unit being *one earth-quadrant per second* :—

Observer.	Date.	Value.

THE SHUCKERT MACHINE AND INCANDESCENT LIGHTING.

The Shuckert machine is, as is well known, a modification of the Gramme, and the first machines of this type were designed for arc lighting. In consequence, however, of the demand for machines for incandescent lighting, M. Shuckert is constructing special dynamos, known as type J. L., for this purpose, adapting them more especially for work with the Edison lamp. The E.M.F. at the terminals at the normal speed is about 110 volts, and it is estimated that generally there is a loss in the conductors of some 10 volts. Other incandescent lamps, such as the Swan, have to be arranged in compound series, so as to utilise this E.M.F. The following table gives some information regarding the machines of this type :—

TABLE RESPECTING J. L. MACHINES.

No.	E.M.F. in Volts.	Strength of Current in Amperes.	Indicated Horse-power.	Revolutions per Minute.	Number of Edison A Lamps.	Number of Edison B Lamps.
J. L. ½	110	3·6	1·0	1500	5	10
1		10·8	2·5	1300	15	30
2		18·0	4·0	1000	25	50
3		25·2	6·0	900	35	70
4		36·0	8·0	700	50	100
5		50·4	11·0	650	70	140

Fig. 1 shows the method of circuiting the A or B lamps. The greater part—say two-thirds—of the lamps can be cut out singly or otherwise without it being necessary to adjust

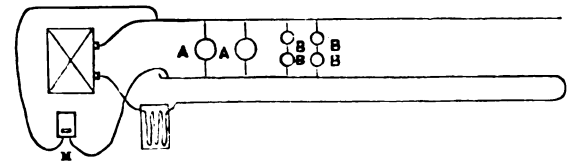

FIG. 1.—Method of Circuiting A or B Lamps.

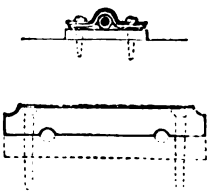
the current regulator. In the parallel method effect depends upon the constancy of the E.M.F. and equality of current to the lamps. If these fluctuate, then the candle-power of the lamp varies. In order to check the E.M.F. a volt meter is put parallel with the wires of the first A lamp, as shown at M, irrespective of the remaining leads by two thin wires. The volt meter used with these machines will indicate up to 120 volts. In ordinary working the needle should indicate from 99 to 103 volts. With regard to the leads, it is recommended that the mains should consist of thick copper wire,

* Paper read before a meeting of the Physical Society, Jan. 27.

Digitized by Google

covered with incombustible insulating material. These main leads are fastened by wooden clamps, with perforations for support, as shown in Figs. 2 and 3. The branch wires used

Fig. 2.



Figs. 2 and 3.—Wooden Clamps for Leads.

are insulated with india rubber. The joints are soldered, and then covered with insulating material.

The size of the conducting wire is determined by the lengths. For the leads to the single lamps the following dimensions are suggested:—

Up to 100 m.	1 mm.
200 ,,	1·4 ,,
300 ,,	1·8 ,,
1,000 ,,	3·0 ,,

For the main leads the following dimensions are suggested:—

For 5 A Lamps.

Length.	Diameter.	Sectional Area.
Up to 100	1 mm.	0·785
200	1·4	1·57
300	1·7	2·36
400	2·0	3·14
500	2·3	3·93
600	2·5	4·72
700	2·7	6·28
900	3·0	7·07
1,000	3·2	7·85

From this table the diameter is calculated as follows:—

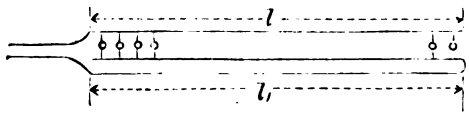


Fig. 4.—Diagram of Method of Obtaining Length of Main Leads.

In order to obtain the length L of the table, the lengths $l_1 + l = L$ are added, and the sectional wire area corresponding to the lengths looked out in the table. If the proposed plan n comprises A lamps (in which two B lamps are always reckoned equal to one A lamp), then the sectional wire area for the return lead $Q = \frac{n}{5} 9$ is to be taken for each of the two parallel wires with which the lamps are connected $Q = \frac{n}{7} 9$.

For plans of incandescent lamps, in which it is a question of greater distances, and where it is never required to extinguish single lamps, the T L machines are constructed, and by their use it is maintained that the dimensions of the wire required is diminished.

Table Respecting T L Machines.

No.	E.M.F. in Volts.	Strength of Current in Amperes.	H.-p.	Revolutions per Minute.	Allowable Lead Resistance in Ohms.	No. of B Lamps.	Parallel Series.
T L ½	55	7	1	1200 1500	0·6	10	1
1	105	8	2	1050-1100	0·6	22	2
2	160	8	3	800-1050	1·2	33	3
3	265	8	4	800 950	2·0	55	5
4	420	8	6 7	700-900	2·5	88	8
5	630-730	8	10-12	600-700	4·0	132-154	12-14

The dimensions of the wire of the leads to the single lamps are to be chosen as indicated above The main leads are to be reckoned in such a manner that the resistance does not exceed the amount given in the 6th vertical column.

For this calculation the following table is used:—

Wire thickness in mm.	7	6·5	6	5·5	5	4·5	4	3·5	3	2·5	2	1·5	1
Resistance per 100 *m* ohms (*s*)	0·043	0·050	0·058	0·070	0·085	0·104	0·13	0·17	0·24	0·34	0·53	0·94	2·12

Fig. 5 shows the method of circuiting in series using the T L machines.

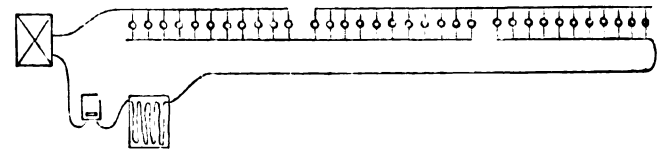

Fig. 5.—Method of Circuiting Lamps in Series.

In the case of the T L machines the working depends upon the constant maintenance of the strength of the current. It is therefore essential to put a current regulator and an ammeter in circuit. The ammeter must indicate up to eight amperes in ordinary working.

In order to be able with these machines to put out of circuit single lamps, or whole parallel series, it is necessary to have the compensation resistances which are to be put in circuit agreeably to the following plan:—A compensation resistance for a B lamp (70 ohms), parallel series for 11 B lamps (six ohms), and so on.

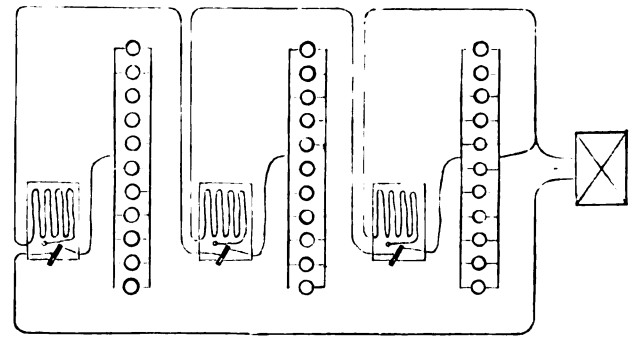

Fig. 6.—Method of Putting Compensation Resistances in Circuit for Parallel Series.

Fig. 6 shows the method adopted for putting in circuit compensation resistances for parallel series.

CANTOR LECTURES.*

Dynamo-Electric Machinery.

By Professor Silvanus P. Thompson, B.A., D.Sc., M.S.T.E.

Lecture II. (concluded).—The Dynamo in Practice.

(continued from page 257.)

Collectors.

In section *ab* of the first lecture, the main points to be observed in the construction of collectors are enumerated. Collectors of substantially such type as there described are common to all dynamos of the first class, except only the Brush dynamo, in which there is a multiple commutator, instead of a collector. The collector of Pacinotti's early machine differed only in having the separate bars alternately a little displaced longitudinally along the cylinder, but still so that the same brush could slip from bar to bar. Niaudet's modification, in which the bars are radially attached to a disc, is a mere variety in detail, and is not justified by successful adoption. In the collector, as used in Weston's dynamo, and in some forms of Schuckert's dynamo, the bars are oblique or curved, without, however, any other effect than that of prolonging the moment during which the brush, while slipping from contact with one bar to contact with the next, short-circuits one section of the coil.

In a well-arranged dynamo of the first class, the sections of the collector are traversed by currents, which run from the

* Reprinted from the *Journal of the Society of Arts*.

Digitized by Google

negative brush in two directions round the successive coils, and meet at that bar of the collector which touches the positive brush. Each section of the coil thus traversed adds its own electromotive force to the current passing through it. Consequently, if one measures the difference of potential between the negative brush and the successive bars of the collector, one finds that the potential increases regularly all the way round the collecting cylinder, in both directions, becoming a maximum at the opposite side where the positive brush is. This can be verified

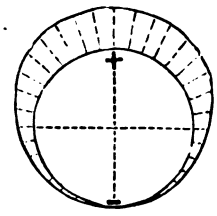

FIG. 25.—Diagram of Potential round the Collector of Gramme Dynamo.

by connecting one terminal of a voltmeter to the negative brush, and touching the rotating collector at different points of its circumference with a small metallic brush or spring attached by a wire to the other terminal of the voltmeter. If the indications thus obtained are plotted out round a circle corresponding to the circumference of the collector, the values give a curve like that shown in Fig. 25, which is plotted out from observations taken upon a Gramme dynamo.*

It can be seen that, taking the negative brush as the lowest

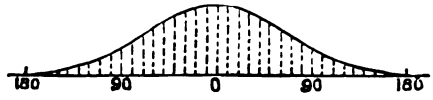

FIG. 26.—Horizontal Diagram of Potentials at Collector of Gramme Dynamo.

point of the circle, the potential rises perfectly regularly to a maximum at the positive brush. The same values are also plotted out as ordinates upon a horizontal line in Fig. 26. This form of diagram shows very clearly that the rise of potential is not equal between each pair of bars, otherwise the curve would consist merely of two oblique straight lines, sloping right and left from the central point. On the contrary, there is very little difference of potential between the collector bars close to the + brush on its right and left respectively. The greatest

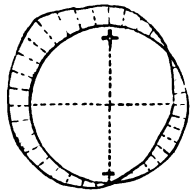

FIG. 27.—Diagram of Potential round the Collector of a Badly-arranged Dynamo.

difference of potential occurs where the curve is steepest, at a position nearly 90° from the brushes, in fact, at that part of the circumference of the collector which is in connection with the coils that are passing through the position of best action. Were the field perfectly uniform, the number of lines of force that pass through a coil ought to be proportional to the sine of the angle which the plane of that coil makes with the resultant direction of the lines of force in the field, and the rate of cutting the lines of force should be proportional to the cosine of this

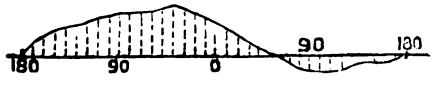

FIG. 28.—Horizontal Diagram of Potentials at Collector or Faulty Dynamo.

angle. Now the cosine is a maximum when this angle = 0°; hence, when the coil is parallel to the lines of force, or at 90° from the brushes, the increase of potential should be at its greatest—as is very nearly realised in the diagram of Fig. 26, which, indeed, is very nearly a true "sinusoidal" curve. Such curves, plotted out from measurements of the distribution of potential at the collector, show not only where to place the brushes to get the best effect, but enable us to judge of the relative "idleness" or "activity" of coils in different parts of the field, and to gauge the actual intensity of different parts of the field while the machine is running. If the brushes are badly set, or if the pole-pieces are not judiciously shaped, the rise of potential will be irregular, and there will be maxima and minima of potential at other points. An actual diagram, taken from a dynamo in which these arrangements were faulty, is shown in Fig. 27, and again is plotted horizontally in Fig. 28; from which it will be seen, not only that the rise of potential was irregular, but that one part of the collector was more positive than the positive brush, and another part more negative than the negative. The brushes, therefore, were not getting their proper difference of potential: and, in part of the coils, the currents were actually being forced against an opposing electromotive force.

I believe that this method of plotting the distribution of potential round the collector will prove very useful in practice, and will explain various puzzling and anomalous results found by experimenters who have not known how to explain them. In a badly-arranged dynamo, such as that giving such a diagram as Fig. 27, a second pair of brushes, applied at the points showing maximum and minimum potential, could draw a good current without interfering greatly with the current flowing through the existing brushes! In fact, I find that this bad distribution, giving rise to anomalous maxima and minima, has actually been patented by a gentleman of the name of Kennedy,* who puts brushes on *six* different points of a collector!

Curves, similar to those given, can be obtained from the collectors of any dynamo of the first class—Gramme, Siemens, Edison, &c.—saving only from the Brush machine, which, having no such collector, gives diagrams of quite a different kind. It is, of course, not needful in taking such diagrams that the actual brushes of the machine should be in contact, or that there should be any circuit between them, though in such cases the field-magnets must be separately excited. It should also be remembered that the presence of brushes, drawing a current at any point of the collector, will alter the distribution of potential in the collector; and the manner and amount of such alteration will depend on the position of the brushes, and the resistance of the circuit between them.

The Brush Dynamo.

Before passing on to the dynamos of the second class, I have some remarks to make on that much mis-understood and mis-described machine, the Brush dynamo. Its armature—a ring in form, not entirely overwound with coils, but having projecting teeth between the coils like the Pacinotti ring—is unique. Though it thus resembles Pacinotti's ring, it differs more from the Pacinotti armature than that armature differs from those of Siemens, Gramme, Edison, Bürgin, &c.; for in all those the successive sections are united in series all the way round, and constitute in one sense, one continuous bobbin. But in the Brush armature there is no such continuity. The coils are connected in pairs, each to that diametrically opposite it, and carefully isolated from those adjacent to them. For each pair of coils there is a separate commutator, so that, for the ordinary ring of eight coils, there are four distinct commutators side by side upon the axis—one for each pair of coils. The brushes are arranged so as to touch at the same time the commutators of two pairs of coils, but never of two adjacent pairs; the adjacent commutators being always connected to two pairs of coils that lie at right angles to one another in the ring. The arrangement is best studied graphically from the diagram given in Fig. 29. In this figure, the eight coils are numbered as four pairs, and each pair has its own commutator, to which pass the outer ends of the wire of each coil, the inner ends of the two coils being united across each other (not shown in the diagram). In the actual machine, each pair of coils, as it passes through the position of least action (*i.e.*, when its plane is at right angles to the direction of the lines of force in the field, and when the number of lines of force passing through it is a *maximum*, and the rate of change of their lines of force a *minimum*) is cut out of connection. This is accomplished by causing the two halves of the commutator to be separated from each other by about one-eighth of the circumference at each side. In the figure it will be seen that the coils marked 1, 1, are "cut out." Neither of the two halves of the commutator touches the brushes. In this position, however, the coils 3, 3, at right angles to 1, 1, are in the position of best action, and the current powerfully induced in them flows out of the brush marked A (which is, therefore, the negative brush) into that marked A'. This brush is connected across to the brush marked B, where the current re-enters the armature. Now, the coils 2, 2, have just left the position of best action, and the coils, 4, 4, are beginning to approach that position. Through both these pairs of coils, therefore, there will be a partial induction going on. Accordingly, it is arranged that the current, on passing into B,

* This diagram was plotted for me, and the measurements made at my request, by Mr. W. M. Morley, who first drew my attention to some of the abnormal phenomena mentioned later.

* British Patent, No. 1,640 (1882).

Digitized by Google

splits, part going through coils 2, 2, and part through 4, 4, and re-uniting at the brush B′, whence the current flows round the coils of the field-magnets to excite them, and then round the external circuit, and back to the brush A. (In some machines it is arranged that the current shall go round the field-magnets after leaving brush A′, and before entering brush B; in which case the action of the machine is sometimes, though not correctly, described as causing its coils, as they rotate, to feed the field-magnets and the external circuit alternately.) The rotation of the armature will then bring coil 2, 2, into the position of least action, when they will be cut out, and the same action is renewed with only a slight change in the order of operation. The following table summarises the successive order of connections during a half-revolution:—

First position. (Coils 1 cut out.)

A—3—A; B $\left\langle \begin{smallmatrix} 4 \\ 2 \end{smallmatrix} \right\rangle$ B; Field-magnets—External circuit—A.

Second position. (Coils 2 cut out.)

A $\left\langle \begin{smallmatrix} 1 \\ 3 \end{smallmatrix} \right\rangle$ A; B—4—B; Field-magnets—External circuit—A.

Third position. (Coils 3 cut out.)

A—1—A; B $\left\langle \begin{smallmatrix} 2 \\ 4 \end{smallmatrix} \right\rangle$ B; Field-magnets—External circuit—A.

Fourth position. (Coils 4 cut out.)

A $\left\langle \begin{smallmatrix} 3 \\ 1 \end{smallmatrix} \right\rangle$ A; B—2—B; Field-magnets—External circuits—A.

responding to the cut out position; and again, on each side of the negative brush there is a region where the polarity is the same as that of the negative brush. Fig. 30 is a diagram of a 6-light Brush taken at one commutator, the main + brush being, however, allowed to rest (as in its usual position), in contact with both this commutator and the adjacent one.

From the foregoing considerations it will be clear that the four pairs of coils of the Brush machine really constitute four sepa-

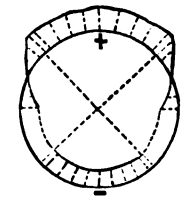

FIG. 30.—Diagram of Potentials at Commutator of Brush Dynamo.

rate machines, each delivering alternate currents to a commutator, which commutes them to intermittent unidirectional currents in the brushes; and that these independent machines are ingeniously united in pairs by the device of letting one pair of brushes press against the commutators of two pairs of coils. Further, that these paired machines are then connected in series, by bringing a connection round from brush A′ to brush B.

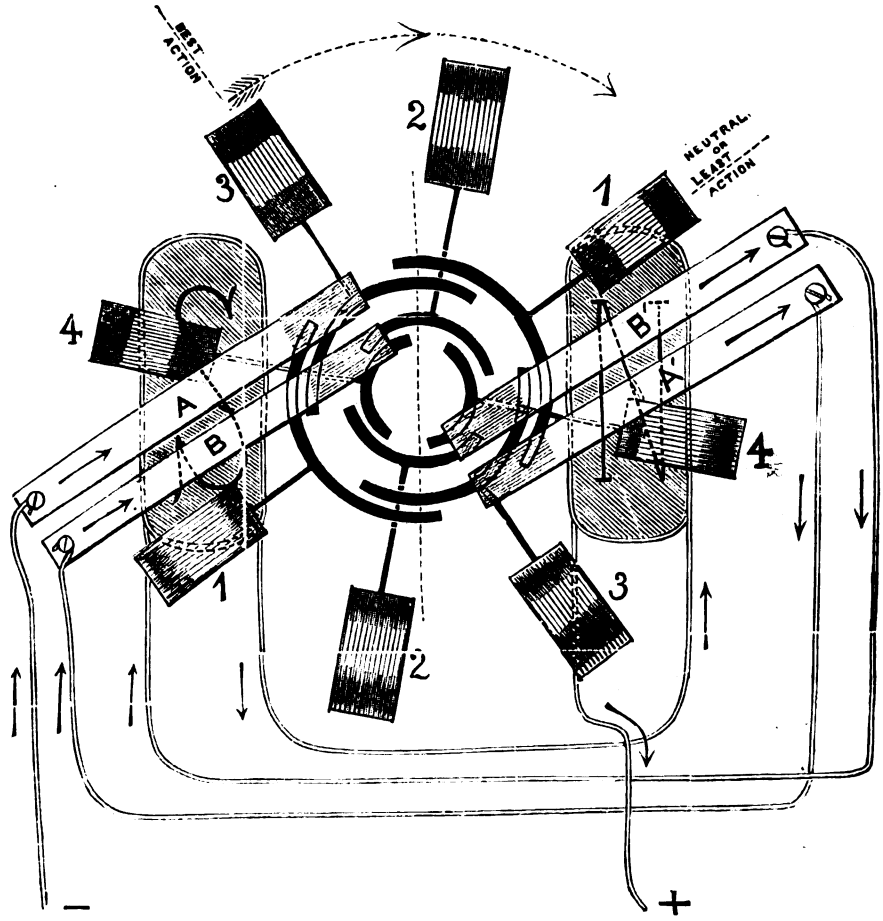

FIG. 29.—Diagram of the Brush Dynamo.

From this it will be seen that whichever pair of coils is in the position of best action, is delivering its current direct into the circuit; whilst the two pairs of coils which occupy the secondary positions are always joined in parallel, the same pair of brushes touching the respective commutators of both.

One consequence of the peculiar arrangement thus adopted is, that measuring the potentials round one of the commutators with a voltmeter gives a wholly different result from that obtained with other machines. For one-eighth of the circumference on either side of the positive brush there is no sensible difference of potential. There then comes a region in which the potential appears to fall off; but the falling off is here partly due to the shorter time during which the adjustable brush connected with the voltmeter and the fixed positive brush are both in contact with the same part of the commutator. Further on there is a region in which the voltmeter gives no indications cor-

The following experiment illustrates the independence of the four pairs of coils in the Brush dynamo.* The usual commutators of a small Brush dynamo were removed and replaced by eight brass collars, to each of which was united one end of one of the four pairs of coils. Against these rings pressed eight separate brushes, and the circuit of each of the four pairs of coils was completed, as shown in Fig. 31, through an ordinary detector galvanometer. On rotating the armature by hand, at a moderate speed, the needles of all four detectors are set vibrating to and fro by the alternate currents, not synchronously, but one after the other. If any one of the four circuits are broken, the others go on as before.

* This beautiful experiment was first shown me by Mr. P. Allen, who kindly fitted up the little Brush dynamo with the eight collars for this occasion.

Dynamos of the Second Class.

I now pass on to dynamos of the second class, in which coils are carried round to different parts of a magnetic field, whose intensity differs in different regions, or one in different parts of which the lines of force run in opposite directions. Fig. 9 of my first lecture illustrated this principle; and we shall now consider how it is carried out in practice. In the early machine of Pixii a single pair of coils was mounted so as to pass in this fashion through parts of the field where the magnetic induction was oppositely directed. Such a machine, therefore, gives alternate currents, unless a commutator be affixed to the rotating axis. Niaudet's dynamo, which may be regarded as a compound Pixii machine, having the separate armature coils united as those of Gramme and Siemens into one continuous circuit, is furnished with the radial collector mentioned above. In the Wallace-Farmer dynamo is very neatly realised the condition of field of Fig. 9, there being a pair of poles at the top arranged so that the north faces the south pole, and another pair at the bottom where the south faces the north pole. The coils are carried round, their axis being always parallel to the exis of rotation upon a disc, there being two sets of coils on opposite faces of two discs of iron set back to back. They are united precisely as in Niaudet's dynamo, and each disc has its own collector. Each bar of the collector is, moreover, connected, as in the dynamos of Pacinotti, Gramme, Siemens, &c., with the end of one coil, and the beginning of the next. In fact, the Wallace-Farmer machine is merely a double Niaudet dynamo with cylindrical collectors. There is a serious objection to the employment of solid iron discs such as these. In a very short time they grow hot from the eddying Foucault currents engendered in them as they rotate. This waste reduces the efficiency of the dynamo. In the dynamo of Hopkinson and Muirhead the disc armature takes a more reasonable shape. Instead of a solid disc of iron to support the coils, there is a disc built up of a thin iron strip wound spirally round a wooden centre. The coils, of approximately quadrangular shape and flat form, are wound upon the sides of this compound disc. The dynamo of Ball (the so-called "Arago-disc" machine) is similar in many respects, but has no iron cores to the armature coils.

Alternate-current Dynamo.

But by far the most important of the dynamos of this second class are those usually known as *alternate-current machines*. This type of dynamo was originally created by Wilde, in 1867. The field magnets consist of two crowns of fixed coils, with iron cores, arranged so that their free poles are opposite to one another, with a space between them sufficiently wide to admit the armature. The poles taken in order round each crown are alternately of north and south polarity, and opposite a north pole of one crown faces a south pole of the other crown. This description will apply to the magnets of the alternate current machines of Wilde and Siemens, to the so-called Ferranti machine, and, with certain reservations, to the machines of Lachaussée and of Gordon. The armature in almost all machines of this type consists of a *disc*, bearing at its periphery a number of coils, whose axes are parallel to the axis of rotation. The principle will be best understood by reference to Fig. 32, which gives a general view of the arrangement. Since the lines of force run in opposite directions between the fixed coils, which are alternately S—N, N—S, as described above, the moving coils will necessarily be traversed by alternating currents; and as the alternate coils of the armature will be traversed by currents in opposite senses, it is needful to connect them up, as shown in the figure, so that they shall not oppose one another's action.

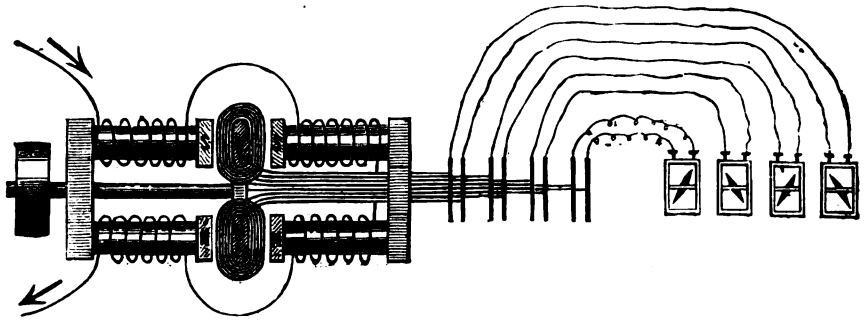

FIG. 31.—Brush Dynamo Arranged with four Detector Galvanometers, showing alternate current induced in independent pairs by coils.

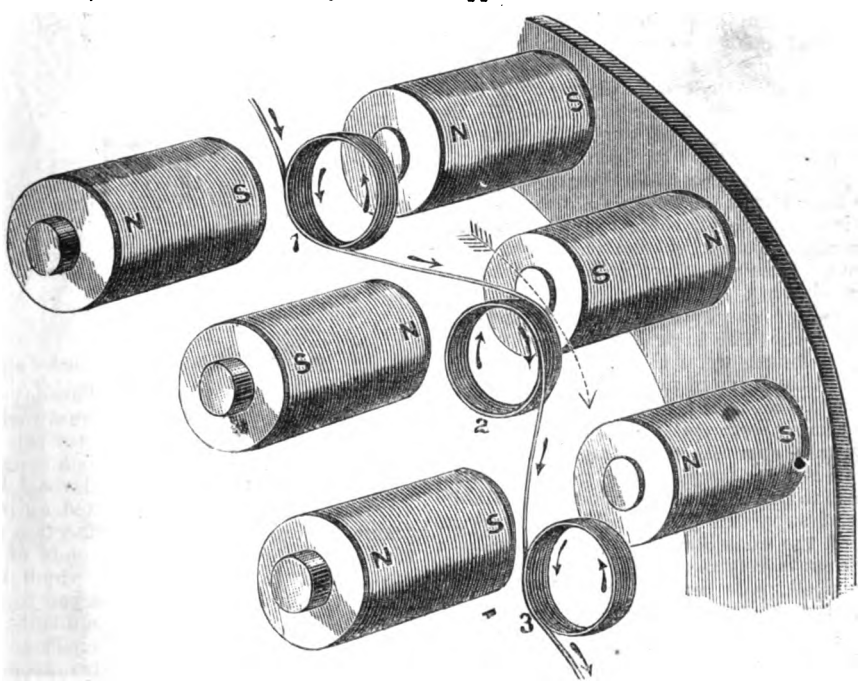

FIG. 32.—Principle of Alternate-Current Dynamos.

In Wilde's dynamo, the armature coils have iron cores, and the machine is provided with a commutator on the same principle as that used by Jacobi in his famous motor of 1838, consisting of two metal cylinders, cut like crown wheels, having the teeth of one projecting between those of the other, so that the brushes make contact against them alternately as they rotate. The brushes are, of course, fixed, so that they do not both touch the same part. This commutator Wilde usually applied to a few, or only one, of the rotating coils, and utilised the current thus obtained to magnetise the field magnets. The main current was not so commuted, but was led away from a simple collector, consisting of two rings connected to the two ends of the armature circuit, each being pressed by one brush.

Siemens prefers to use a separate direct current machine to excite the field magnets of alternate-current dynamo. In the

Digitized by Google

armature of the latter the coils are wound usually without iron, upon wooden cores. In some forms of the machine, the individual coils are enclosed between perforated discs of thin German silver. When currents of great strength are required, but not of great electromotive force, the coils are coupled up in parallel arc, instead of being united in series.

In a dynamo by Lachaussée, which very strikingly resembles the preceding one, there is iron in the cores of the rotating coils. But the main difference is that the rotating coils are the field magnets, excited by a separate Gramme dynamo, whilst the coils, which are fixed in two crowns on either side, act as armature coils in which currents are induced.

Gordon's dynamo, the largest yet made, is constructed on the same lines as the Lachaussée machine; but with many important improvements. In the first place, there are twice as many coils in the fixed armatures as in the rotating magnets, there being 32 on each side of the rotating disc, or, in all, 64 moving coils; while there are 64 on each of the fixed circles, or 128 stationary coils in all. The latter are of an elongated shape, wound upon a bit of iron boiler plate, bent up to an acute V form, with cheeks of perforated German silver as flanges. The object of thus arranging the coils, so that the moving ones shall have twice the angular breadth of the fixed ones, is to prevent adjacent coils of the fixed series from acting detrimentally, by induction, upon one another. The alternate coils of the fixed series are united together in parallel arcs, so that there are two distinct circuits, in either or both of which lamps can be placed; or they can be coupled up together. Great care appears to have been taken, in the construction of this large machine, to guard against the appearance of Foucault currents, by arranging the cores, frames, and coils, so that all metal parts of any size shall be slit, or otherwise structurally divided at right angles to the direction of the induced electromotive forces.

Yet another alternate-current dynamo, identical in many respects with the Siemens alternate-current dynamo, has lately been brought out, under the name of the Ferranti machine. As in the machines of Wilde and Siemens, the electro-magnets form two crowns with opposing poles. The point of difference is the armature, which, like that of Siemens, has no iron cores in its coils; but which, unlike that of Siemens, is not made up of coils wound round cores, but consists of zigzags of strip copper folded upon one another. There are eight loops in the zigzig, and on each side are sixteen magnet poles; so that, as in Gordon's dynamo, the moving parts are twice the angular breadth of the fixed parts. The advantage of the armature of zigzag copper lies in its simplicity of construction. Sir W. Thomson, who is the real inventor of this armature, proposed originally that the copper strips should be wound between projecting teeth on a wooden wheel. He also proposed to use as field magnets a form of electro-magnet of the kind known as Roberts's, and also used by Joule, in which the wires that bring the exciting current are passed up and down, in a zigzag form, between iron blocks projecting from an iron frame. I am not aware that this particular suggestion has been adopted as yet in practice.

Much more might be said concerning the two machines last described—the Gordon and the Thomson dynamos—but time does not permit me to dwell longer upon them. And, indeed, I am not at all convinced that this type of machine, though at present it appears to be the fashionable one, is destined to prove of such very great value, simply because I doubt whether any dynamo that yields alternate currents can compete with continuous-current machines. For the purposes of a general system of distribution, where more than one dynamo must be available, and also for the purpose of supplying motors, alternate-current machines are quite out of the question. I will not, therefore, dwell longer upon them, than merely to remark that, besides the disc armatures now described, pole armatures have been employed in alternate-current machines by Gramme, Jablochkoff, and by Lontin. Hefner Alteneck has gone a stage further, and, by the device of employing a disc armature in which the number of coils differed by two, or some other even number, from those of the field, and by the employment of a multiple-bar collector with complicated cross connections, has succeeded in converting this type of dynamo into a continuous-current machine.

Thomson's "Mouse-mill" Dynamo.

One other dynamo, not belonging to the type I have been dealing with, is worthy of mention. This is Sir W. Thomson's "mouse-mill" dynamo. I have noticed, *en passant*, several points in this machine—the form of its field magnets and their coils, the internal electro-magnets, &c. The armature is a hollow cylinder, made up of parallel copper bars, arranged like the bars of a mouse-mill (whence the name of the machine). These bars are insulated from each other, but are connected all together at one end. At the other, they serve as collector-bars, and deliver up the currents generated in them to the "brushes." As the armature is a hollow barrel, with fixed electro-magnets within, it cannot be rotated on a spindle, but runs on friction rollers, by one or more of which it is driven.

Dynamos of the Third Class.

I now come to the third class of dynamos—those in which rotation of a conductor effects a continuous increase in the number of lines of force cut by the device of arranging one part of the conductor to slide on or round the magnet.

The earliest machine which has any right to be called a dynamo was, in fact, of this class. Barlow and Sturgeon had shown that a copper disc, placed between the poles of a magnet, rotates in the magnetic field when traversed by an electric current from its axis to its periphery, where there is a sliding contact. Faraday, in 1831, showed that by rotating a similar disc mechanically between the poles of a magnet continuous currents were obtained. These he drew off by collecting springs of copper or lead, one of which touched the axis whilst the other pressed against the amalgamated periphery. He was thus "able to construct a new electrical machine."* "Here, therefore, was demonstrated the production of a permanent (*i.e.*, continuous) current of electricity by ordinary magnets." But Faraday did not stop short with ordinary magnets; he went on to employ the principle of separate excitement of his field magnets. "These effects were also obtained from *electro-magnetic poles*, resulting from the use of copper helices or spirals, either alone or with iron cores. The directions of the motions were precisely the same; but the action was much greater when the iron cores were used than without."† The invention of the dynamo dates, therefore, from 1831, and Faraday was its inventor, though he left it to others to reap the fruits of his splendid discovery.‡ Such a machine, however, is impracticable, for several reasons. The peripheral friction is inadmissable on any but a small scale; moreover, the disposition of the field-magnets necessarily evokes wasteful eddy-currents in the disc, which, even if slit radially, would not be an appropriate form of armature for such a limited magnetic field.

Another method of obtaining a continuous cutting of the lines of force is indicated in Fig. 33, where a sliding conductor travels

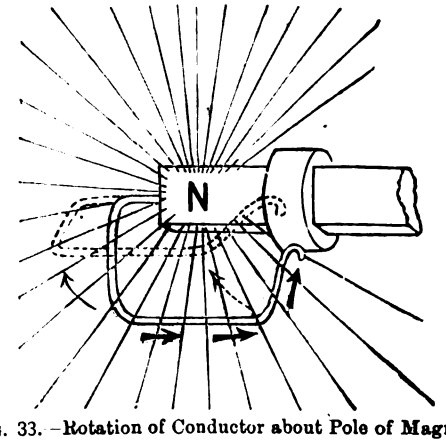

Fig. 33.—Rotation of Conductor about Pole of Magnet.

round the pole of a magnet. Faraday even generated continuous currents by rotating a magnet with a sliding connection at its centre, from which a conductor ran round outside, and made contact with the end-pivots which supported the magnet.

A similar arrangement was devised by Mr. S. Alfred Varley, about the year 1862. He rotated an iron magnet in a vertical frame, having a mercurial connection at the centre. The current which flowed from both ends of the magnet toward the centre was, in this machine—which, by the kindness of Mr. Varley, I am able to exhibit to you to-night—made to return to the machine, and to pass through coils surrounding the poles of the rotating magnet, thus anticipating the self-exciting principle of later date. Mr. Varley also proposed to use an external electro-magnet to increase the action.

Quite recently the same fundamental idea has been worked upon by Messrs. Siemens and Halske, who have produced a so-called "unipolar" machine.§ In this remarkable dynamo there

* "Experimental Researches," § 83. † "Experimental Researches," § 111.

‡ "Experimental Researches," § 158:—"I have rather, however, been desirous of discovering new facts and new relations dependent on magneto-electric induction, than of exalting the force of those already obtained; being assured that the latter would find their full development hereafter." Can any passage be found in the whole range of science more profoundly prophetic, or more characteristically philosophic, than these words, with which Faraday closed this section of his researches.

§ This sounds like a *locus a non lucendo*, for the machine has two poles. But the name is derived from the term "unipolar induction," which Continental electricians give to the induction of currents by the process of "continuous cutting," which we are now dealing with. I do not adopt the term, as it is needlessly mystifying.

Digitized by Google

are two cylinders of copper, both slit longitudinally to obviate eddy-currents, each of which rotates round one pole of a U-shaped electro-magnet. A second electro-magnet, placed between the rotating cylinders, has protruding pole-pieces of arching form, which embrace the cylinders above and below. Each cylinder, therefore, rotates between an internal and an external pole of opposite polarity, and consequently cuts the lines of force continuously by sliding upon the internal pole. The currents from this machine are of very great strength, but of only a few volts of electromotive force. To keep down the resistance, many collecting brushes press on each end of each cylinder. This dynamo is actually at work for electro-plating.

The only other dynamo of this class, of which I have seen any published notice, is one recently patented by Mr. E. L. Voice, in which a coil armature, wound upon an iron ring, is so placed that the iron ring is itself one pole of a magnet, a projecting pole-piece from the other pole being fixed near it, so that the coils fixed upon one pole glide round and cut the lines of force proceeding from the other pole. Whether this machine will be a practical one remains to be seen.

We are, however, far from having arrived at finality in the design and construction of dynamo-electric machines. All we can yet say is that we appear to be approaching the time when practice will no longer be a species of blundering along into success or failure. For every day theory is more and more brought to bear in practice, and will soon enable us to predict with certainty beforehand what will be the merit of a dynamo of any particular design: and even to say not only what its cost will be, and what its efficiency and maximum duty, but also how many volts of electromotive force, and how many amperes of current it will put at our disposal. In short, the application of theory in the manufacture of dynamos must rapidly lead to great and substantial improvements in the dynamo in practice.

(TO BE CONTINUED.)

ARRANGEMENT OF MACHINES AT BRÜNN.

The accompanying diagram of the arrangement of the machines at Brünn Theatre explains itself. The engine and boiler are in an adjacent building, and were built by the Estern Brünnen Machinen-Fabriks-Gesellschaft. There are three boilers—two in general use, one in reserve. The illustration shows the method of connecting the machines, and this is, perhaps, the most important use of such illustrations for students, many of whom may be called upon, sooner or later, to arrange installations themselves. The work has been carried out under the Société Electrique Edison of Paris. The machines run from 10 to 2 daily for rehearsal, and in the evening from 5:30 to 10:30, making a total of nine hours daily. The experiment at Brünn is due more especially to the enterprising Herr Gustav Winterholler-Bürgermaister of Brünn, who built the theatre. As is usual in questions of progress, there was a good deal of opposition encountered and overcome before the work could be commenced. However, energy succeeded, and success has silenced the adverse critics.

NOVEL USES FOR ELECTRICITY.

It has often been said in disparagement of science and invention that we owe our most useful discoveries to accident. Generalisations such as these are of no practical value except perhaps to enemies of the patent laws, who never condescend to particulars. Whatever truth there may be in the assertion, a general statement of quite opposite import would be true to the same extent, such for example as that the most baneful or mischievous discoveries, assuming there are any, have been due to mere accident also. Both propositions have something to be said for them, and both alike must be urged with much reservation. The part that accident has played in the field of discovery is a very uncertain one, and on one point only can we speak with confidence, namely, that accident is perfectly impartial in its operations, doing us an ill turn with as much unconcern as it does us a good one.

It was nature and not inspiration that revealed to us the deadly powers of electricity. This was a long while ago; and, ever since we were able to take an intelligent view of the revelation, no pains have been spared to devise means for safeguarding our fellow creatures from its consequences, some men indeed having sacrificed their lives in the endeavour. It did not occur to anybody to "invent" a form of lightning in order to kill his neighbour; on the contrary, the chief occupation of the ingenious in this branch of science was for many years that of applying electricity to therapeutic uses, healing the sick, and even resuscitating the seemingly dead, being among the chief objects aimed at. This was turning the tables on nature, giving her, so to speak, a lesson in humanity. But we have changed all that. True the newspapers invite us pictorially to purchase curative appliances, and we are still entreated to throw physic to the dogs, putting our trust in "nature's remedy," meaning of course a mild dose of lightning. But these things are for the infirm. For the more robust, mentally, as well as constitutionally, Mr. Lane-Fox, the *Medical Press*, and certain correspondents of the daily press, have lately proffered suggestions more startling and more tangible. According to one of these authorities electricity ought to be utilised for the slaughtering of aged horses; according to another we ought to adopt the same means for doing to death our condemned criminals; whilst a third, the medical paper above mentioned, warns us against the surreptitious use of the electrical current for the purposes of secret murder.

All this we may safely affirm is the result of pure accident, of several accidents in fact, whereby people have been killed by lightning of man's devising. We could have well spared this discovery, and so perhaps could the aged horses, for whose prompt despatch Mr. Lane-Fox proposed to utilise it. We do not want to see the electric current diverted to the use of private assassination; and, whatever the assassin himself may say about it, we do not want to annihilate him by the same agency. But, unwelcome as may be the fact we must put up with it as we put up with dynamite and the other deadly sins. They have all been turned to harmless account, and we expect the same of the killing capabilities of electricity. There is nothing, therefore, to be said against Mr. Lane-Fox's or the correspondents' proposals considered from the utilitarian point of view. But there are other points of view besides this, and we wish to dwell upon them for a moment.

The proposal to slaughter animals by electricity is not original. Dr. Richardson, whose name is associated with many curious suggestions, tried this one some years ago. We do not exactly know why. Nominally the idea was to cause a painless death. Human experience in these matters is very limited, and as we cannot consult the animals it is impossible to affirm what sort of death they like best, and which one is the least painful. As a fact, however, it was found, firstly, that the meat so slaughtered was injured, some of it being rendered unfit for food; and, secondly, that the animals sometimes came to life again, much to the satisfaction no doubt of the professional wielder of the pole-axe, though probably not to that of the poor beasts. We suppose we must allow that the doctors know best, but ordinary people who have seen a bullock stunned by an experienced hand, attach very little significance to the struggles that may afterwards ensue. Sensation is extinguished with the first blow—at all events the sensation of pain. Some creatures are very stupid, and others very unreasonable. A hen, for example, will run away minus her head, and we all know what eels are capable of in the way of obstinately presuming to live. But nobody supposes that feeling survives the first slash of the knife, or if it does survive, all we can say is that the amount of prolonged cruelty inflicted on fish and poultry calls for the interposition of the humane far more than does the case of

Digitized by Google

the higher creation, who, if they feel more acutely, die much more quickly.

But there was one other objection to Dr. Richardson's proposal, and it applies equally to Mr. Lane-Fox's for the slaughtering of used-up horses, namely the danger to the slaughterers. We understand that the animal is to stand on a metallic floor, which is connected to an electrical appliance of great power, and this in turn to a wire and a knob. If the horse's forehead comes in contact with the knob the horse will be stricken dead. Given an intelligent horse duly trained to touch the knob, and the business is done. To train and persuade an average slaughterer to bring the knob to the horse would be not more easy, and far less safe. This and the combined protest of every old maid against the injury done to the food of their favourite pets may be trusted to keep Mr. Lane-Fox's device out of the knacker's yard for a long while yet to come.

As to substituting an electric wire for a hempen cord, we think we discussed this proposal once on a former occasion. The number of transactions lately quoted, especially from the sister isle, may now for a moment tempt the proprietors of new inventions lacking customers to embark in that line of business. But only for a moment. One difficulty we feel confident would prove insurmountable, that of finding an—well, an operator. There is, as we have already said, much beside mere utility to be taken into account in work of this sort, not the least of which is sentiment, and what we have hitherto called self-respect. Some rough things have still to be done in this world, which had better be done roughly, for if performed scientifically they would in reality be rendered more barbarous for all the parties concerned.

We suppose it is the business of the medical profession to look after our safety in matters relating to secret homicide, otherwise we could hardly excuse the *Medical Press* even hinting at the possibility of murder by means of the electric current. The danger seems purely imaginary, especially as the impossibility or improbability of discovering the cause of death is, we feel sure, a complete mistake. Let the medical profession look to it, however, if we are wrong, for we confess that electrical science would be somewhat at a loss to act as detective *after* the work was done. Perhaps our security from this kind of danger, if any such threaten us, lies in the absence of technical skill, and the risk to the operator himself. Let us hope so at least, and hope, too, that the accidental discovery of the dangers attending unskilful handling of a powerful electric current may not lead to its use for any of the purposes we have here commented upon.

CORRESPONDENCE.

THE ACTION OF MICROPHONES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to Mr. Rathbone's letter, I quite understood his remark, and in reply draw his attention to the G.S. spring, the function of which is not only to provide a path for the current but also to *prevent* the possibility of a disruptive effect taking place in the circuit at the point of contact on the transmitter being subjected to too loud speaking, such as would occur were no such preventive measure taken, and which does take place when the small spring sticks to the diaphragm by rust, and is thereby prevented from acting, with the result which is patent to all who have had any practical experience with the instrument; therefore it is, in this form of transmitter, absolutely necessary.

I pointed out in one of my former letters that the effect of pressure (in the microphonic sense) on carbon exists within certain limits; and I have not the slightest doubt, if he can devise a means of fixing binding screws to a piece of carbon *without exceeding* and being somewhat within *this limit*, together with a suitable means for mounting same, maintaining a constant initial pressure, he will be quite successful. I might mention in passing that I have examined many Crossley-Gower and other dead-weight contact transmitters, but with entirely the reverse effect which he anticipates. But more of this particular class of transmitter at some future date, the introduction of which at present would only render the argument more complex.

This correspondent states that the reason carbon alters its resistance more than brass is due to *form*, not *material*, which I confess is good going Greek to me if this statement is to be accepted in the literal sense, but on reading further I am under the impression that he means texture of surface. If this is right, I beg to inform him that the higher the polish on the carbon button, the better the action, and in cases where the polish has been accidentally destroyed by rough usage or bad packing when in transit, it becomes necessary to renew the surface and repolish it. It is clear, then, that this argument falls to the ground. He further says some very fine brass filings with a little dust thrown in, would show a more variable resistance. Where has this to be thrown, into the button, or in the eyes of the uninitiated?

I am obliged to "W. E. H." for calling my attention to the paragraph referring to circuit resistance, which scarcely conveys my meaning. If he will remove the period following "diaphragm" and put it after "diminished," the new sentence will then run, "A corresponding diminution of current takes place when the pressure is removed," to which he can add, "and the button allowed to regain its normal resistance."

In the experiment mentioned, illustrating the action of a blow on the masses suspended, first, he will allow that the force or energy of the blow must have a certain ratio to the weight of the masses suspended to produce displacement, and that, if a sufficiently light blow be given, the total energy would be absorbed by the elastic bodies themselves without causing any displacement whatever. Therefore, *a distinct blow may be given without the outermost mass being disturbed, so far as actual contact is concerned.* 2nd. In the case of three masses being suspended, his argument would hold good with a blow of a given energy, and with no other force but that of gravity acting on each of them equally and in the same direction; but how widely different is the effect when we come to consider the action of a spring on the same terms. It will be sufficient to consider the G.S. spring only. If he takes a Blake and examines this spring he will find, when the carbon button is removed, the spring will lift the platinum stud outwards (*i.e.*, in the direction of the carbon block when in position) and upwards, while gravity would pull it downwards, and in a direct line with its suspension. The resultant of these two forces would be closely approximate to a right angle with the line of suspension, and be in the *direct line with the thrust*, therefore its natural tendency is to fulfil the function for which it is designed, viz., the *maintenance of a closed contact.* It is clear, then, that I agree with your correspondent that the spring modifies the action of gravity in the matter, and to what degree he may satisfy himself if he takes the trouble to remove the spring carrying the platinum stud from a Blake and suspend in its place a platinum bead by a single thread of gimp. If he is then content with the instrument as a transmitter—and contentment means happiness—he is a happy man, indeed. I will now endeavour to reduce the foregoing to practice.

It so happens when testing a transmitter it is usual to ascertain how delicate and responsive it is to subdued speech. Suppose he were to take a properly adjusted Blake, and whisper or speak in a moderate way to it. The whisper will be perfectly well heard, the impulses will correspond to the light blows by which a displacement of the parts is impossible. If he will now shout a sentence at the pitch of his voice so as to correspond with the heavy blows and produce the necessary displacement, would the sentence be understood by the

Digitized by Google

receiver? Certainly not. Instead of speech being transmitted there would be nothing conveyed but a jarring noise.

The sum total of all this simply proves, and by his own argument, that speech is not produced in a Blake transmitter by an intermittent contact. "He is a poor engineer who is hoist with his own petard."

If W. E. H. has any other substance which will act *as well as carbon*, I will be much pleased to receive a sample of it. The difference of the action between carbon and brass points to one conclusion only, which is unnessary for me to reiterate.

I am sorry, Mr. Editor, I cannot induce this gentleman to sign his name.

I have read "Gordius's" letter with interest. His final experiment would seem to be somewhat similar to a Hunning transmitter, but not having seen the instrument, I can pass no opinion on it. If he could spare a pair for a few days, I would like very much to make a trial of them. He does not state how many Leclanchés would be required to excite them.—Yours &c, R. D. SMILLIE, Electrician.

National Telephone Company (Limited), Glasgow.
Jan. 25th, 1883.

THE STORAGE OF ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Reading the interesting address delivered by Mr. Willoughby Smith at the Society of Telegraph Engineers on the 18th inst., I am a little surprised at the few remarks made on the above subject. We know the storage of electricity is a great desideratum, but when it is said that two years have passed away without any useful results following the importation of the marvellous box from Paris, which was so graphically described by Sir William Thomson, or, in other words, that no progress has been made in this direction, this, I think, is a slight mistake, as the storage cells known as the Sellon-Volckmar accumulators, an improvement on the wonderful boxes of M. Faure, are giving useful results. I cannot conceive a more suitable purpose than telegraphy to which secondary cells might advantageously be applied. What could be more simple, clean, and economical than a set of these cells, and a small gas motor? I have no hesitation in saying that accumulators *properly* constructed on the above plan should last at least five years. At the end of that time it would not take as many hours to replace the worn out plates.—Yours, &c., H. A. KENT.

154, Culford-road, N., Jan. 29, 1883.

FITTINGS FOR INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With your permission I would venture to call attention to the different fittings for incandescent lamp sockets now in use. There are, I believe, no less than three different sockets for Swan lamps, one having 7-16in. female fitting, one $\frac{3}{8}$in. male fitting, and one with the so-called "burner size," 5-16in. taper thread. The Lane-Fox have two sockets, one with 7-16in. and one $\frac{3}{8}$in. female fitting. The Duplex use 5-16in. taper thread, and Maxim uses $\frac{3}{8}$in. female for his sockets. All sockets for Edison lamps have hitherto had $\frac{3}{8}$in. female fitting. I would suggest that some universal size be adopted by all the companies for their sockets. This would make the various systems, so far as the lamps and sockets are concerned, interchangeable, and would be of great convenience, not only to individuals but to manufacturers at large.

I think attention to such details as these would go far to take away the opinion, at present far too prevalent, that electric lighting needs much simplyfying before coming into general use.—Yours, &c., J. B. V.

THE RECTIFICATION OF ALCOHOL BY ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your editorial of August 26, 1882, you state that alcohol is open to electrical treatment both for "ageing" and rectification. Will you or any of your readers kindly oblige by giving any information you may have respecting such treatment, or say where I could find particulars for myself?—Yours, &c., READER.

STATIC ELECTRICITY AND QUANTITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. Sprague, on page 231, I must in the first place respectfully decline the suggested perusal of the work to which he alludes.

If we take matter for granted we know force only as change of momentum, and therefore we must necessarily define force in terms of certain changes in the state of matter. If, on the other hand, we take force for granted, we have to define matter in terms of force. Mr. Sprague takes exception to Professor Clifford's definition of force as the change of momentum of a body considered as depending upon its position relative to other bodies on the ground that force cannot *be* change of momentum, and, metaphysically, I think the statement is open to objection, just as we may object to the statement that the velocity of a body moving uniformly is the space described in unit time. The full statement of this would be—The velocity of a body moving uniformly is that state of the body in virtue of which it changes its position in space, and is measured by the space traversed in unit of time. We might in the same way say that, the force acting upon a body owing to its position relative to other bodies is that state of the system of bodies in virtue of which the given body changes its momentum, and is measured by the change in the momentum of the given body in an unit of time, supposing the unit of time to be taken so small that that state is sensibly the same at the beginning and end of the interval. The usual expressions are certainly preferable on the score of simplicity, and with ordinary attention to the meaning of words they do not seem to me to be liable to misconception. Mr. Sprague says that unit force and unit energy are the same. Now, force is a directed quantity and energy is not, which is quite sufficient to show that force and energy cannot be the same thing.

The argument from Faraday's ice-pail experiments is a direct deduction from the experimental results, and does not depend upon any theory of electricity, and it is certainly no answer to the argument to say that it has been "thoroughly misunderstood."

With regard to Mr. Sprague's complacent opinion that Maxwell was gradually adopting his views, and that "most of the leading electricians are unconsciously adopting the same course," discussion is unnecessary, as the opinion can do no harm to any one, and probably gives satisfaction to Mr. Sprague. As Mr. Sprague "does not care to go into questions of dimensions," permit me to point out to any of your readers who have not considered the subject, that a physical equation, the members of which were of different dimensions in the fundamental units, would involve the absurdity that the truth of the equation would depend on the units of length, time, and mass employed.

Mr. Sprague finally quotes an illustration of Sir William Thomson's of the well-known fact that electrical conductivity is, in the electrostatic system of units, of the same dimensions as velocity, but to this he adds the totally incorrect statement that a current is a velocity. Now, a velocity is a length divided by a time, but electric current is a quantity of electricity divided by a time; that is, the dimensions of current are, in the electrostatic system, $L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-1} \times T^{-1} = L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-2}$, while those of velocity are $L T^{-1}$.—Yours, &c.,

G. W. VON TUNZELMANN.

IMPROVED GALVANIC BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: After carefully reading over the description of Mr. Parkhurst's improved galvanic battery in your issue of the 20th inst. (Slip), I cannot exactly see how the action de-

Digitized by Google

scribed takes place. If any of the subscribers to your valuable paper would give the chemical formula for the action I think it would make the description clearer, as well as supply a very interesting equation. The above information would greatly oblige—Yours, &c., CHEMICAL AFFINITY.

ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As a subscriber to *The Electrician*, I beg to trouble you with the following questions, and hope that you will answer them in your next issue:—

I want to make some accumulators (I have already done so on a small scale, and have succeeded so far as the energy and duration of the current is concerned) which can be charged by a small dynamo made purposely for this work, and which is sold at the office of *L'Electricité*, 16, Rue Croissant, Paris, at 400 francs.

Now, the E.M.F. of this dynamo is 80 volts, and the current in amperes 9 (one of these, however, is required for the field magnets); what will be the number and weight of accumulators that I can charge with this dynamo, so as to give me, when discharged, sufficient current for one Swan incandescent lamp of $2\frac{1}{2}$ carcels, or an Edison A or B lamp? If I knew the weight required in these cases, I could make a battery for ten or twenty lamps.

What number and weight of accumulators can I use, the tension of which shall not overcome that of the dynamo when charging?

I should be much obliged if you or your readers could help me in the matter.—Yours, &c., J. H. DISERENS.

Care of Mr. P. A. Moussy, Manufacture des Soieries.
Moscow, January 8/20, 1883.

A SAFETY LAMP FOR MINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 27th instant you devote a paragraph to the "Electrical Safety Lamp for Mines." Will you permit me to make one or two corrections? In the first place, Mr. Ellis Lever is not an M.P., and is not to be confounded with the member for Galway, the two being in no way connected. Secondly, there is an error in the address; it is Culcheth Hall, Bowden. Thirdly, the offer of £500 is not confined to electric lamps, though, no doubt, that will be the light most likely to fulfil all the required conditions, and, therefore, will, in the near future, be the miners' safety light, and best guide in this hazardous calling.

It might be interesting to your readers to know that Mr. Ellis Lever, who has made this handsome offer, is the father of Mr. Charles Lever, whose arc lamp you noticed some time since, and who is now lighting up the Tropical Department at the Crystal Palace with a new and improved arc lamp.—Yours, &c., GEO. HOWELL.

City Club, Ludgate-circus, E.C.,
Jan. 30, 1883.

ANSWER TO CORRESPONDENT.

X.—Awaiting the completion of foreign patents.

BOROUGH OF SHEFFIELD.

ELECTRIC LIGHTING ACT, 1882.—PRELIMINARY REPORT OF CONRAD W. COOKE, M.S.T.E. & E.

The corporation of the Borough of Sheffield having resolved to apply to the Board of Trade for a provisional order under the Electric Lighting Act of 1882, authorising them to supply electricity for public and private purposes within the said borough, and I having been requested by the corporation of the said Borough of Sheffield to advise them as consulting engineer with respect to the said provisional order, and the carrying out of the provisions therein contained, I beg to submit the following preliminary report:—

The application of the science of electricity to industrial purposes, especially to the production of artificial illumination, the transmission of mechanical power to a distance, and the allied industries of electro-plating and electro-typing has, during the last few years, made such important progress that it may fairly be said to have passed from the experimental region of the laboratory of the physicist to take its place amongst the recognised industries of the world; and the International Exhibition held at Paris in 1878, and still more emphatically the Exposition d'Electricité which was held in the same city last year, have demonstrated to the public the practical capabilities of the application of electricity to illumination as well as to other hardly less useful industrial purposes. The result of these practical demonstrations has been that a strong and insatiable public demand for electricity has arisen, and a large and rapidly-increasing number of electrical installations has sprung up in every civilised portion of the globe, but especially in this country, in France, Belgium, and Germany, and in the United States of America.

The lighting of a considerable number of the streets of Paris and London was quickly followed by other towns, and a new branch of industry has arisen out of this public demand of such magnitude that electric lighting companies, with capital in the aggregate amounting to several millions of pounds, have been formed in bewildering numbers, and the question has become of so much public importance as to demand the recognition of the Legislature. In August of the present year the Electric Lighting Act of 1882 was added to the statutes, and this was immediately followed by a set of rules issued by the Board of Trade with respect to applications for licenses and provisional orders.

The immediate consequence of the passing of this Act was that the corporations of nearly all the important towns in the United Kingdom were applied to and served with notices from some five or six electric lighting companies, or other proprietors of systems of electric supply, of their intention to apply for licenses or provisional orders for the establishing, in each of the towns applied to, electric power generating stations, workshops and machinery, with powers for the breaking up of the public streets and highways for the purpose of laying the conductors or electric mains, and for the doing of all such things as are necessary to the establishment of electrical installations upon a large scale.

The giving consent to the obtaining of provisional orders for such purposes to private companies or individuals would virtually amount to the abandonment of the rights of corporations and other local authorities to the control of the streets and highways within their own boroughs or districts over which they have had hitherto and would have otherwise control; and there has been a very general and very decided feeling on the part of corporations and other local authorities, to resist so serious an interference with their rights within their respective districts.

To prevent this interference there appears to be but one course open to the local authority of a borough or district, and that is (in accordance with Rule II. of the Board of Trade rules), themselves to apply for a provisional order to supply electricity within their borough or district, and thus maintain in their own hands the control of their streets and highways, and at the same time not place their town behind other towns in the adoption of electric illumination, which, at no very distant period, must, in my opinion, be generally adopted for town lighting.

In order to comply with the requirements of the Board of Trade I am advised that, although it is open to the Corporation of Sheffield to apply for a provisional order specifying the area of supply to be the whole area of the borough as constituted under the provisions of the Acts relating to municipal corporations, it is not necessary to take compulsory powers for the whole of that area, but in order to show that the corporation has, in applying for an order, a *bonâ fide* desire to make a substantial trial of the electric light within the borough, and not merely to keep others from supplying electricity therein, it is necessary that the corporation, in applying for a provisional order, shall undertake, within a specified time, to give a supply of electricity for private purposes within a certain district of the town, such district not being necessarily very large, as compared with the area of the whole borough, but that throughout that limited district they must bind themselves to supply at a uniform rate of remuneration any intending consumer who may apply for it.

I would, therefore, propose that the corporation should, in connection with the provisional order, undertake to make an experimental lighting of a certain limited area of the town, and by "area" I do not mean an area in the ordinary acceptation of the word—bounded by a circular or polygonal boundary, and embracing every house within it—but a selection of a few of the most important streets specified in a schedule to the provisional order, and not to include (except in instances likely to prove ad-

Digitized by Google

vantageous or desirable) the smaller streets and blocks of buildings included within the meshes formed by the network of streets proposed to be included in the district to be lighted.

I have prepared a plan indicating the district over which I would propose to supply electricity for private purposes, which might be distributed from a single supply station placed upon any land sufficiently near to the installation that could advantageously be obtained by the corporation, or, preferably, from two stations situated respectively at or near the opposite ends of the district to be lighted. The district I would recommend the corporation to illuminate (as a preliminary step, and in order to comply with the rules of the Board of Trade) embraces a series of streets extending, generally speaking, from north-east to south-west, that is to say, from the river end of Waingate, near to the Lady's Bridge, to the southern end of Pinstone-street, near to Moorhead and to Barker Pool, near the Albert Hall, and consists of the following streets and thoroughfares, the houses and other buildings belonging to which should be included in the area of compulsory supply:—

(1) Waingate.	(8) Market-place.
(2) Castle Folds.	(9) High-street.
(3) Castle-street.	(10) Church-street.
(4) Angel-street.	(11) Leopold-street.
(5) King-street.	(12) Fargate.
(6) OldHaymarket.	(13) Barker Pool.
(7) Market-street.	(14) Pinstone-street.

The above series of streets measures in the aggregate about a mile and a quarter, and represents rather over two miles of house frontage, seventy-five per cent. of which is occupied by shops.

Leaving for future consideration the *public* lighting of the above district, I will confine myself to the illumination of the houses and shops which are directly belonging to the streets of which it is composed, and the first question which presents itself for consideration is whether the illumination shall be effected by arc lights or by incandescence lamps, or by a selected combination of the two. There cannot be a doubt that for large open spaces, for large halls and for many factories and mills the illumination by the electric arc is the most convenient, as it is the most economical, but on the other hand it is a system that requires a certain amount of skilled attendance, and the lamps employed require to be fitted with new carbon pencils every day, and not only have the carbons to be supplied but certain adjustments have occasionally to be made to the lamps. These operations, though simple in themselves to any one accustomed to them, are such as would prevent my recommending any arc system for indiscriminate private lighting, for which purpose it is impossible for the apparatus within a private house to be too simple, being as it is more or less in the hands of domestic servants and other unskilled people.

For the above reasons I am bound to recommend for the general lighting of the district the principle of lighting by incandescence, of which, as the corporation knows, there are several systems owned by as many proprietors. I would, therefore, recommend the laying out of the installation as if nothing but incandescence lights were to be employed, but I would, at the same time, point out that the doing so does not *necessarily* exclude the employment of arc lights in special cases where they might be more suitable, for it is quite possible—although I do not recommend it—to substitute an arc lamp for a corresponding number of incandescence lamps, and thus have both arc lights and incandescence lamps burning on the same circuit. I should prefer (if there were a demand for arc lights sufficient to justify the outlay), the laying of a separate circuit for them, and actuated by a separate dynamo machine or series of machines, so that the one system would be perfectly independent of the other, but whether this should be done or not can only be determined by the local opinion and other local circumstances.

The attendance required with incandescence lights is simply the turning them on or off, as required, and the renewal of lamps when destroyed, and as the average life of an incandescence lamp is several thousand hours, and its renewal is as simple an operation as putting a candle into a candlestick, the attention required by consumers is altogether inconsiderable, and does not even include any lighting operation except the turning on of a small tap-like "switch."

For uniform and steady illumination there is nothing to be desired in incandescence lights, they are perfectly steady, being subject to no fluctuation—which cannot be said of the very best arc lamp at present in the market—although all the arc lamps employed to any considerable extent at the present time are great improvements on those of but a few years ago, and I have no doubt arc lighting will be still further improved by the introduction of regulating lamps still more readily adjusting themselves to the variations of the current transmitted through them, and side by side with these improvements the system of the self-adjustment of dynamo machines to the work put upon them from time to time will become more and more developed.

In order to arrive at anything like an accurate estimate of the amount of illumination required, that is to say of the number of lights of a given photometric value that will be necessary to be supplied with electricity, I would suggest that the occupiers of premises belonging to the district to be lighted be asked the number of lights they would require (estimating at about eight electric incandescence lamps for every ten gas burners at present employed), or if that be considered inadvisable, a reliable person might be requested to survey the district with the object of estimating as nearly as possible, the number of gas-lights at present employed in the shops and other buildings attached to the streets mentioned in the schedule, and from an estimate so produced the number of equivalent electric lights might be computed.

In the absence of such information, and for the purpose of making a general estimate of what may be considered the requirements of the installation, I have taken an average number of houses throughout the district by considering every 24 feet run on each side of the street as representing one house, and upon this method of computing I take it that there are 550 average houses in the district. In a district consisting of private dwelling-houses and but few shops it is fair to estimate that the illumination by incandescence lamps may be effected by allowing an average of ten lamps per house of an average frontage of 24 feet, upon which calculation there would be required 5,500 lamps. Inasmuch, however, as the district consisting of the streets set forth in the schedule on page 2 of this report is composed, in so large a proportion, of shops likely to require a larger number of lights, I think it would hardly be safe to estimate a smaller number of lights per house than eighteen, which would bring the number of lamps for the district to 10,000. It is not in the least degree probable that every proprietor in the district would adopt the electric system at once, and we may assume that there will be a considerable number who will refuse to adopt it altogether. On the other hand, there will be others (and I expect many among the proprietors of important shops) who will require a larger number of lamps than the estimated allowance of eighteen lamps for every 24 feet of frontage, and so the deficiency of some will be made up by the greater demand of others.

To drive these ten thousand lamps I estimate would require about 1,250 actual horse-power when all working together. This power estimated at about an eighth of a horse-power per lamp is, I am aware, greater than that quoted generally by proprietors of electrical incandescence systems, who, as a rule, state that an average of ten twenty-candle lamps can be driven per horse-power, but I do not feel justified in recommending the adoption of a less driving power than one horse-power to every eight lights; but this estimate is an outside one, and should allow a margin for ensuring easy working.

I would here point out that under most of the recognised incandescence systems the cutting out of lamps is accompanied by a corresponding saving of motive power, and, therefore, of fuel consumed, so that if at any time 100 lamps be in operation, or 1,000, or 10,000, the power absorbed will bear a proportionate relation to the number of lights in actual operation.

It may be of some service if I in this place give a few figures by way of roughly estimating the probable cost of such an installation, and which may be divided under three headings, that is to say:—

I.—Producing or Generating Plant.
II.—Distributing Plant.
III.—Fixed Property.

I. Producing or Generating Plant may be divided into two sections:—

(1) *Motive Power.*
Consisting of
- (*a*) Steam engines.
- (*b*) Boilers.
- (*c*) Steam and other fittings, shafting, &c.

(2) *Electric Apparatus*:—
Consisting of
- (*a*) Dynamo electric machines.
- (*b*) Indicating, testing, and other accessory apparatus—such as switches, cut outs, meters, &c.

II.—Distributing Plant:—
1. Electric mains and conductors.
2. Distributing boxes.
3. House service lines.

III.—Fixed Property:—
1. Land.
2. Buildings.

Digitized by Google

CAPITAL REQUIRED.

I.—PRODUCING PLANT:—

(*a*) Six 250 I.H.P. compound steam engines, *i.e.*, five working and one in reserve at £750	£4,500		
(*b*) Six Lancashire boilers at £780	4,680		
(*c*) Pipes and connections	1,000		
(*c*) Fixing, &c.	1,000		
		£11,180	
Twelve 1,000-light dynamo-electric machines, at £800	£9,600		
Fixing, starting, &c.	1,000		
		£10,600	
			£21,780
		£2 3s. 6d. per lamp.	

II.—DISTRIBUTING PLANT:—

(*a*) 6,250ft. of streets, with mains laid on both sides, at £3,000 per mile	£7,200	
(*b*) 60 distributing boxes, at £8	480	
(*c*) 400 house service lines, at £3	1,200	
	£8,880	£8,880
	17s. 9d. per lamp.	

III.—FIXED PLANT:—

(1). Land, (2). Buildings ... Estimated together at	£10,000	
		£10,000
	£1 per lamp.	

IV.—To which may be added for contingencies, engineering, &c., at 10 per cent. £4,066

£0 8s. 2d. per lamp.

£44,726

Total capital £4 9s. 5d. per lamp.

A.—The above figures are on the assumption that the boilers employed are of the ordinary Lancashire type, and the engines are compound high and low pressure non-condensing engines.

(B).—Should it be decided to adopt compound high and low pressure condensing engines so as to effect the greatest possible economy of fuel with Lancashire boilers, the item for motive power must be increased to £15,530, estimated as follows:—

Five 300 i.h.-p. compound engines—that is four to work and one in reserve—delivered and set at £1,700 each	£8,500
Foundations for ditto	900
Nine Lancashire boilers, seven working and two spare, delivered on setting at £450 each	4,050
Boiler settings	1,080
Pipes, floor plates, &c.	1,000
	£15,530

(C).—If, on the other hand, "locomotive" boilers be decided upon, in order to occupy a minimum of space and to be able to get up steam very quickly, the item for motive power will become £16,700, made up as follows:—

Five compound engines, as above	£8,500
Foundations for ditto	900
Seven "locomotive" boilers at £870 each	6,090
Settings for ditto	210
Pipes, floor plates, &c.	1,000
	£16,700

SUMMARY.

(A).—If compound non-condensing engines be employed—

Electric apparatus	£10,600	
Motive power	11,180	
Distributing plant	8,880	
Land and buildings	10,000	
	£40,660	
Contingencies, engineering, &c., 10 per cent.	4,066	
		£44,726

(B) If compound condensing engines and Lancashire boilers be employed:—

Electric apparatus	£10,600	
Motive power	15,530	
Distributing plant	8,880	
Land and buildings	10,000	
	£45,010	
Contingencies, engineering, &c., 10 per cent.	4,501	
		£49,511

C.—If compound condensing engines and "locomotive" boilers be employed—

Electric apparatus	£10,600	
Motive power	16,700	
Distributing plant	8,880	
Land and buildings	10,000	
	£46,180	
Contingencies, engineering, &c., 10 per cent.	4,618	
		£50,798

The above figures are further summarised in the following table:—

CAPITAL.	With Compound High-pressure Engines and Lancashire Boilers. A	With Compound Condensing Engines and Lancashire Boilers. B	With Compound Condensing Engines and "Locomotive" Boilers. C
Electric apparatus	£10,600, = £1 1s. 2d. per lamp.	£10,600, = £1 1s. 2d. per lamp.	£10,600, = £1 1s. 2d. per lamp.
Motive power	£11,180, = £1 2s. 4d. per lamp.	£15,530, = £1 11s. per lamp.	£16,700, = £1 1s. 4d. per lamp.
Distributing plant	£8,880, = 17s. 9d. per lamp.	£8,880, = 17s. 9d. per lamp.	£8,880, = 17s. 9d. per lamp.
Land and buildings	£10,000, = £1 per lamp.	£10,000, = £1 per lamp.	£10,000, = £1 per lamp.
Contingencies, engineering, &c.	£4,066 = 8s. 2d. per lamp.	£4,501, = 9s. per lamp.	£4,618, = 9s. 3d. per lamp.
Total	£44,726, = £4 9s. 5d. per lamp.	£49,511, = £4 18s. 11d. per lamp.	£50,798, = £5 1s. 7d. per lamp.

(TO BE CONTINUED.)

ON THE MOLECULAR RIGIDITY OF TEMPERED STEEL.*

BY PROFESSOR D. E. HUGHES, F.R.S.

During the course of some recent researches the writer has been enabled by the aid of the induction balance to perceive some remarkable molecular differences between the constitution of iron and of steel.

There are numerous papers in the *Comptes Rendus* from 1830 to 1850, in which it is suggested that tempered steel is a true alloy of iron and carbon, the carbon being present in varying degrees according to the temperature at which the alloy was formed, and being afterwards rendered permanent by sudden cooling.

In a late discussion on this subject† the writer made a few remarks, in which he pointed out the marked difference between softened and tempered steel, as to solubility in dilute sulphuric acid, and expressed the opinion, formed from these and many previous experiments, that tempered steel was a true alloy.

He has since continued these experiments, not, however, to prove the chemical composition of tempered steel, but to investigate its peculiar molecular structure, as indicated by the induction balance.

The apparatus necessary to perceive the effects of stress or torsion, as described in this paper, is exceedingly simple. Suppose, for instance, that we take an ordinary single-coil electro-magnet, and join its terminals with that of a telephone or sensitive galvanometer. If we now pass a current from a battery through the iron core alone of the electro-magnet we have a sharp click at each make and break of the current. This effect was discovered by Page, and fully described by De La Rive.‡

If we keep the current passing constantly through the core we have no effect, but if we then give a slight torsion or twist to the core either to the right or left we at once hear a sharp click; and if we keep the torsion constant and then make frequent interruptions of the battery we have a greatly increased sound at each make or break, indicating a greatly increased force of electric current.

In order to investigate this phenomenon the author constructed a special though very simple apparatus.

A coil having a large aperture is fixed to a board; two small

abutments or supports at a few inches distance on each side of the coil allow us to suspend or fix an iron wire passing through the aperture, which then becomes the core of an electro-magnet. This forms the essential portion of the apparatus. The iron or copper wire rests upon the two supports, which are 20 centims. apart; at one of these it is firmly clamped by two binding screws, while the opposite end can turn freely. The wire is 22 centims. long, projecting two centims. beyond its support. On the projecting end is a key or arm, which serves as a pointer moving on a graduated circle, and gives the degree of torsion which the wire may receive. A binding screw allows us to fasten the wire, after turning the pointer to any degree of torsion, and thus preserves the required stress as long as is necessary.

The exterior diameter of the coil is 5½ centims., and that of the interior vacant aperture 3½ centims.; the width is two centims. Upon this coil is wound 200 metres of No. 32 silk-covered copper wire. This coil is fastened to a small board, so arranged that it can be turned through any desired angle in relation to the iron wire which passes through its centre; and it can also be moved so as lie over any portion of the 20 centims. length of wire, in order that different portions of the same wire may be tested under a similar stress.

The whole of this instrument, as far as possible, should be constructed of wood, in order to avoid all disturbing inductive influences of the coil upon other pieces of metal.

The iron wire at its rear or fixed end is joined to or makes contact with a copper wire, which returns to the front part of the dial under the board and parallel to the coil, thus forming a loop. The free end of the iron wire is joined to one pole of the battery; the copper wire under the board is joined to a rheotome, and thence to the other pole of the battery.

The coil is joined to a telephone or a sensitive galvanometer; and we may either pass the current in the manner described, or may reverse all the communications, passing the current through the coil instead of the wire, and listening with the telephone to the induced currents upon the iron wire alone.

In order fully to understand the phenomena which takes place, we must bear in mind Faraday's discovery of electric magnetic induction, namely, that any wire conveying an electric current induces in general a momentary secondary current in any independent circuit whose wires are parallel to it; the effect being at its maximum when two wires are parallel, diminishing as the angle of these wires is increased, and at 90deg. being absolutely zero. Consequently, when we place a copper wire in the axis of the coil, with the above apparatus, and pass a current through this wire, we find no effect whatever, no trace of induced currents; simply for the reason that this copper wire crosses all of the wires of the coil at an angle of 90deg. We also find that no effect takes place upon torsion being applied to the copper wire. If we now place a small rod of iron parallel with the conducting copper wire, we have no effect; but if the iron rod is turned at an angle to the wires a current is observed, the force increasing from parallelism to an angle of 45deg., and decreasing again from this angle to 90deg., where we have again no effect. The conducting copper wire thus induces electric magnetism in the iron rod, and this magnetism reacts upon the coil; but this only holds as long as the rod is not parallel to either coil. At an angle of 90deg., although at its maximum of electric magnetism, the iron rod becomes parallel to the coil upon which it reacts; consequently we have again a zero of current. In place of one rod, we may insert several short rods, and if these are all turned together in the same direction, we have similar effects.

Knowing this, we can understand that if each molecule of a rod were endowed with separate magnetic power, and if we could cause these to rotate through any angle round the axis, we might expect similar reactions to those of the small separate iron rods already mentioned.

If we replace the copper wire spoken of by an iron wire, and send intermittent currents through it, we still have no induced current upon the coils; but the instant we apply a very slight torsion, say 10 or 20 per cent. of one turn, we at once perceive strong induced currents. These are positive for right-hand torsion, and negative for left-hand torsion. Thus we can not only produce induced currents, but, without changing the direction of the primary electric current, we can change the induced currents, making them positive or negative as we please; exactly as would occur if we rotated in opposite directions the small iron bars, placed side by side with the copper wire.

At this point it becomes important to know if these effects are produced by the twist given by torsion to the whole mass of the wire, or if each molecule turns separately and independently round its axis. There are many proofs that the latter view is correct. For, assuming the former, then, if an iron wire be twisted permanently by thirty or more entire turns, we should expect greatly increased effects as compared with those given by 10 or 20 per cent. of a single turn. But we find that after the first instant of torsion we have no increase of force in the current, even with a molar twist of 30 whole turns, which must of course produce a certain molecular twist; we find that the slightest torsion, say of 10 per cent. backwards, is sufficient to reverse the current, and thus more than neutralise the whole inclination which had been given to the molecules by the permanent torsion. Again, if, whilst the iron wire is under the influence of torsion, we bring near it one pole of a large natural magnet, laid in the direction of the wire, we find that the currents gradually diminish, until when the magnet touches the wire we at last produce zero. The polarised molecules, which under the influence of torsion lay at a certain angle with the axis, have thus been caused to rotate back again, and become parallel. Again, if we approach the same pole with the magnet at right angles to the wire, we find that the current gradually returns to zero (and therefore the molecules to parallelism) when the magnet is about two inches distant; but on bringing the magnet still nearer, they pass the zero point, now giving increased reversed currents, until they reach a maximum, when the magnet is close to the wire. We have thus rotated the molecules from their original angle of torsion, say of 45deg. to the right, through zero to 45deg. to the left. If this view is correct, we should expect that we might produce electric currents of reversed directions without the aid of any battery, by simply giving a to and fro torsion to the wire; and this proves to be the case. For we may join the telephone either to the exterior coil or to the simple circuit of the wire, and we shall then hear a sharp click at each movement of torsion to the right and left; thus imitating and reproducing all the effects which would be obtained by rotating a separate magnet through different angles of inclination with the wire.

There are many proofs which confirm this view*; but as the object of the author is to show the remarkable difference which exists between iron and steel in this respect, he will confine himself to showing the very great apparent rigidity of the molecules of tempered steel as compared with those of iron.

A very remarkable difference appears when we turn to tempered steel. For here we find that at certain degrees of temper (*e.g.* that known as blue or spring temper) there are only slight traces of molecular disturbance or rotation, no matter how many mechanical turns or twists we may put on the wire. In fact, the molecules here seem fixed and homogeneous throughout the mass. We have perfect molar elasticity, but no traces of rotation of one part over another—in other words, no molecular elasticity. Thus in iron we have an elasticity due solely to the freedom of molecular motion. In hard steel, on the contrary, we have but slight molecular freedom, with great molar elasticity, in which the separate molecules do not rotate separately, but all as one mass.

It is necessary to point out this difference of molar rigidity, as shown in tempered steel and in iron, because tempered steel is not the only form which thus differs in its mechanical and physical qualities from iron or soft steel. A similar difference is shown also by several known alloys of iron.

We can decrease the apparent rigidity of steel by the application of heat; for if we pass a constant and powerful current through the steel wire, which previously gave but feeble traces of rotation, and then heat this wire to red heat, a strong induced current is gradually produced. The current here has the power of rotating the polarised and heated molecules, and so giving out comparatively strong induced currents. But on cooling this wire it is impossible again to reduce it to silence. The molecules remain rigid, but at an angle to the axis. With iron, however, upon the application of heat under the same circumstances, we have a most violent rotation, which entirely disappears on cooling—proving again the great comparative freedom of its molecules.

We might believe that all the above effects in steel are due, not to the rotation of the molecules, but to the more or less retentive or "coercitive" force of steel with regard to permanent magnetism. But coercitive force, whilst it may suffice to explain, according to accepted views, the retention of magnetism, does not explain why we can produce positive and negative currents by right or left-handed torsions, nor why we should have induced currents by torsion. If we accept the term coercitive force as simply applicable to each molecule, then we have still to consider the greater freedom of motion of these molecules in iron than in steel. It is a general belief (which the author has hitherto shared) that the molecules of tempered steel have far greater coercitive force than those of iron. A simple experiment will, however, prove this not to be the case. For if we suppose that the molecules of iron turn with far greater freedom, it follows that they should also turn by the application of far less force. Now, if we take a soft iron and tempered steel wire, and place them at a given distance from a suspended

* "Molecular Magnetism," by Professor D. E. Hughes. *Proceeding* of the Royal Society, March 7-17, and May 10, 1881.

Digitized by Google

magnetic needle, after finding them both to be free from magnetism, and we then magnetise these wires by drawing them over the poles of a natural magnet, then we may, no doubt, find as usual that the tempered steel has a far greater amount of remaining magnetism. But if, instead of this, we limit the reactive force of the natural magnet, by placing a piece of wood, say ½in. thick, between the magnet and the wire magnetised, thus limiting and controlling the force to any degree, according to the interval between the magnet and the wire to be magnetised, we then find, on magnetising these two wires with a weak reactive force, and again observing its action upon the needle, that the soft iron still shows powerful retentive or coercitive force, whilst the tempered steel has but feeble traces of magnetism, or none at all. Thus, contrary to the author's previous convictions, it appears that *iron possesses more coercitive force than steel whenever the inducing force is limited, and within the range of iron.*

If iron merely possessed greater coercitive force than steel, it would be impossible for us to employ soft iron in electro-magnets requiring quick changes of magnetism. But although in the previous experiment the remaining magnetism was far greater in the iron than steel, yet the magnetic force of the iron, whilst under the influence of the permanent magnet was some twenty times greater than its remaining magnetism; whilst with the steel there was but a slight difference in the force developed whilst it was under the feeble influence of the natural magnet, and when this was withdrawn.

Assuming the freedom of motion of the molecules to be greater in iron than steel, it occurred to the author that he should be able to free the soft iron from its remaining magnetism by simple vibration of the wire. This was found to be the case. An iron and steel wire are magnetised to saturation, or both may be given the same amount of permanent magnetism. We will suppose that they both deflect the suspended needle through 40deg. Now taking the steel wire and fastening one end in a brass vice, give its free end a slight pull to set it in vibration, it will be found that the steel has lost but 2deg., having still 38deg. of permanent magnetism, which cannot be further reduced by repeated vibrations. The instant, however, that a similar vibration is given to the soft iron wire, its remaining magnetism nearly all disappears; there is left at most 2deg., or in some cases only a trace. Thus the molecules are seen to be so comparatively free in iron that mere vibration will aid them in rotating. These two wires were again observed vibrating whilst under the influence of the permanent magnet. There was then a greater magnetic effect produced in the iron wire than previously; the vibrations aiding the rotations produced by the natural magnet.

The author was desirous to render visible this freedom of iron and rigidity of steel, so that these effects might be actually seen. For this purpose we may take three glass tubes, or ordinary phials, of any length or diameter, say 10 centimetres in length by 2 centimetres in diameter. If we now put iron filings in these tubes, leaving about one-third vacant, so as to allow complete freedom in the filings when shaken, we find that each tube, when magnetised, retains an equal amount of residual magnetism, and that this all disappears upon slightly shaking the tube; we are thus imitating the effects of vibration. But if in one of these tubes we pour melted resin (or in fact any slightly viscous liquid, such as petroleum, suffices) we then render these filings more rigid, and then we can no longer produce by shaking the disappearance of its residual magnetism. In pouring in petroleum we have apparently been introducing a strong coercitive force; but we know that it can only have the mechanical effect of rendering the iron filings less free to turn, and so comparatively rigid. If we desire to see the effect of torsion, we have only to shake the filings so that when the tube is held horizontal the vacant space is above, and rotate slightly (but without shaking) the tube containing the free filings about a horizontal axis. Its remaining magnetism instantly disappears upon rotation, although we evidently have not changed the longitudinal position of its particles. A similar effect takes place upon a soft iron wire, for if we magnetise it and observe its remaining magnetism, we find that upon giving a slight torsion to this wire, its remaining magnetism instantly disappears—a similar effect to that in the rotating tube of iron filings.

The author has remarked in these researches that in all alloys of iron the molecules are far more rigid than in the pure metal; and further that, with steel, tempering adds greatly to this rigidity. He is now engaged upon the question of the effect of different tempers on the same steel, and hopes in a future paper to be able to bring the results before the Institution.

Soft steel, when compared with hard drawn iron, shows that the mechanical hardening of iron has not in any great degree diminished its molecular freedom. Even the softest steel shows a high degree of molecular rigidity, as compared with the hardest iron, but far less than that of tempered steel. This would seem to indicate that steel in its softest state is still an alloy, though only feeble quantities of carbon may be held in that condition.

We thus perceive that a great physical change takes place in iron upon the slightest alloy with carbon; and that tempering produces this change in its highest degree. The writer, therefore, is strongly in favour of the view propounded long since, that steel when tempered is an alloy, containing fixed carbon in a far greater quantity than when soft. We know the physical properties of magnetic oxide of iron, of iron and tungsten, and of iron and sulphur. Now, in all these the writer has found that the iron loses its molecular freedom when even slightly alloyed. The physical results are, therefore, the same as those produced in tempering steel; and the induction balance thus indicates strongly that tempered steel shows the characteristics of a true alloy.

We could not have such a great physical difference between iron and steel, as above noticed, except by corresponding changes in its mechanical properties; and it is with a view of bringing out these relations in a discussion on this point that the author has ventured to bring his views before the Institution of Mechanical Engineers.

THE EASTERN TELEGRAPH COMPANY (LIMITED).

The twenty-first half-yearly ordinary general meeting of the Eastern Telegraph Company (Limited) was held on Thursday, January 25, 1883, at the City Terminus Hotel, Cannon-street, London, E.C., under the presidency of John Pender, Esq., M.P.

Mr. WELLS, acting for the secretary, read the notice convening the meeting, also the minutes of the last ordinary general meeting, and of the extraordinary general meeting held on the 3rd August last, which were signed by the chairman.

The report having been taken as read,

The CHAIRMAN said: I see that we have taken more than usual care to make the present report as full as possible. We have condensed a very great—a very large amount of matter into a very small compass, but I think it has placed our position before you in a manner that those who run may read [hear, hear]. However, before going more into detail, I think it is right that, as usual, I should draw your attention to what I call the ups and downs of our working during the last six months. Our revenue, as you observe, for the half year ended 30th September, 1882, amounted to £341,151, against, in the corresponding period of last year, £282,834, being an increase of £58,317. Analysing these figures, we find a very satisfactory growth of traffic throughout our system, with one or two exceptions. In the first place, the South African Company's dividend was at the rate of 8 per cent., instead of 10 per cent., being less by £3,900 than in the same period of 1881. There is, however, an increase of £900 in the receipts from the Black Sea Telegraph Company. The Indian traffic, on account of the crisis in Egypt, suffered very materially, but, thanks to our arrangement with the Indo-European Company, our receipts did not suffer. I will merely glance at the differences, for it is well you may carry them in your mind on this occasion, because the last half year has been altogether an eventful one. The ordinary expenses of the Company amounted to £69,809, against, in the corresponding period of 1831, £67,498, or an increase of £2,311. The main cause of this increase is our having opened four new stations—Athens, Karystos, Trieste, and Corfu. We have likewise had extra expenditure owing to the increased volume of traffic from Egypt and other places during the war. Repairs to cables amounted to £52,801, against £47,228, or an increase of £5,573. In abstract "C" you have the full details of this extra expenditure, and I may mention that this is an expenditure which will be always more or less fluctuating, as it arises very much from the circumstance whether we have many interruptions in our cable or are fortunate in being without them. The general expenses in London were £6,670. In the September half year of 1831 they were £6,521, or an increase of £149. In salaries there is an increase of £37. The office expenses show an increase of £161, rent and taxes an increase of £31—in fact there is only an increase of £278, but on the other hand there are decreases in other items of £129. These are the London expenses. The working expenses at stations in the September half of 1831 amounted to £47,418. In 1882 they amounted to £50,287. There are increases in these expenses of £3,522, and decreases of £653. The increase is caused, as I have said, by the four new stations which have been opened. The other expenses are of a very minor nature. The use of patents has cost us £2,750, the same as before, and the foreign agencies have cost us £1,339 against £1,198. There is an increase there of £141, being part expenses of a special agent who was sent to Constantinople. The other items are all very much the same. The directors' remuneration is the same; the auditors' remuneration is the same. The amount carried forward this half year is £56,836, against in the same period of 1881 £29,504, or an increase of £27,332, after paying a bonus of 1s. per share on the ordinary capital, making, with the previous payments, a return for the half year at the rate of 6 per cent. per annum [applause]. Our dividend as a rule at this time has been at the rate of 5 per cent., and at the end of the year we have given the bonus; but we felt so satisfied with our present position that we thought it well to give you a proportion of the bonus this half year, and I hope when I next see you we shall be able to confirm the dividend at the rate of 6 per cent. for the year.

When I had the pleasure of addressing you in July last, I referred to the state of our cables. We had at that time two breaks or interruptions in the Red Sea. We had one very important interruption in the Bay of Biscay, which had given us a very great deal of trouble. You all know what rough water that is; and we had to wait for favourable weather to be able to effect this repair. I am glad to say that it was accomplished, and the cable was picked up from 2,700 fathoms of water, showing clearly what I have very frequently stated

Digitized by Google

at these meetings, that after all we have got a property. We can repair cables in the deepest water. It is expensive, I admit, but we can find where the fault is, and are able to repair the cable.

I then stated that we were in a peculiar position in regard to our ships. It was our duty to maintain, if possible, telegraphic communication between Egypt and England. It was important not only for our dividend, but equally important as regarded broad national interests, and I hold that the position we now occupy makes us—in fact, it is imperative on us that we should always consider those interests. Political as well as commercial interests are involved, and, therefore, while we benefit ourselves by maintaining our cables, we are very largely maintaining what I call great public interests. We went at this with a will. We brought our ship from the Red Sea, and left one of our cables there still faulty. We brought the "Chiltern" into the Mediterranean for two reasons. The first reason was, we knew that our land system was likely to be interrupted, and that the "Chiltern" would be more useful in the Mediterranean than in the Red Sea. Fortunately we did this. She was of the greatest possible use as you are aware, and her name has become generally known on account of the great services she rendered off Alexandria in maintaining telegraphic communication with Europe.

We also found our land lines being interrupted in Egypt. We were cut off from Port Said. It is true the Canal was open, but there was no communication unless through Turkey to Port Said. We saw that this was most undesirable. The traffic through the Canal is of immense importance to the shipowning interests of this country, and we thought it right to try and secure a communication along the Canal. We entered into negotiations with the Government. Those negotiations were more or less prolonged, as you know Government negotiations generally are; but we felt it was of the greatest possible importance to the public service, and also to the interests of this Company that we should be ahead of the Government in maintaining or in endeavouring to maintain our communications. We therefore resolved to take the ship that was at that time engaged in repairing the cable in the Bay of Biscay. We sent the ship out to Alexandria with sufficient cable to connect Alexandria with Port Said. We did not do that a day too soon. If we had waited till we had got the decision of the Government, I do not know what the consequences would have been. We, however, sent out the ship, and when the order was given to lay the cable we were in a position to do so at a few hours' notice. We laid the cable, and communication was opened between Port Said and Europe, and between Suez and India. We were enabled after great anxiety to obtain a land line. At first we could not make an arrangement with the Suez Canal Company, for reasons you may have read in the newspapers. This was owing to that venerable engineer who has gained a world-wide reputation, and I think he has been a great public benefactor; but still, when men have a strong bias about an enterprise of their own creating, they are apt to take views which are not so broad as they might have taken earlier, and we had great difficulty in getting our permanent communication along the Canal. Thanks, however, to the help of our Government, and to the broad views of the Khedive, we made an arrangement with the Suez Canal Company. In future we shall have an alternate line—a line along the Suez Canal connecting the Suez end with India, and the Port Said end with Egypt, so that we have two strings to our bow, if anything occurs in Egypt. This has been done at very considerable expense, but we were masters of the position. We availed ourselves of our position to do a great public good, but we also thought we should do good to the Company, and I am glad to say that we have secured a very important interest in favour of this Company. I doubt very much if what we have got will not give us pretty nearly full right to work the system that connects England with India without interference from any other parties. At all events, we shall do our work very badly if a second party comes alongside of us.

The last six months have been, perhaps, the most eventful period of this Company's history: but it is very satisfactory to know that, notwithstanding our ups and downs, notwithstanding the interruptions to our Indian traffic, we have had the largest returns this half year that we have had in any similar period of the Company's history. We have spent more money in the way of expenses than we have done before, but, notwithstanding this great expenditure, we have gained, through the active telegraphic communication carried on by the Government and the Press between the seat of war and Europe, a return which amply repays us, and we have given accommodation which I hope will be appreciated by the general public as it has been by the Government, for I may say that we have received from the Government, besides what I have mentioned as material benefit, a letter thanking the Board and those who have carried out this work for the public spirit displayed in very peculiar and extraordinary circumstances.

Now, a company like this (as I remember a gentleman that I see before me remarked) cannot stand still. We must either go forward, and go forward in these days of progress at a very considerable pace, or go backward.

I have alluded to our South African traffic, and, as we have found that it was a valuable traffic, it could not be placed in any degree in a secondary position. The cable, as you know, goes from Aden to Zanzibar, and on to Durban. Up to Aden we have to carry not only the Indian, Colonial, and Chinese traffic, but also our South African traffic. It was impossible to make the service what we desired it should always be, and, therefore, we had no hesitation in at once making arrangements to lay down an additional cable from Suez to Aden, so as to maintain that traffic in the efficient state we think it ought to be in. We did this also from the knowledge that the Red Sea was virtually in the future to be a sea for our cables, and, therefore, we did not hesitate to carry out what has been referred to in the report—contracting for and laying a cable between those two points, and we have no doubt we shall get a very good return from that outlay. We have also during the six months carried out a concession we had from the Turkish Government of laying a cable from Malta to Tripoli. That has been done, and successfully done, and I believe that will be an additional source of revenue to the Company.

Now, gentlemen, notwithstanding all this expenditure, in which, I believe, we have served the shareholders and general public, I believe we have given satisfaction to our Indian, China, the Cape, and our Australian customers.

I am glad to say that, as I have said, we are able to-day to put a very fair and satisfactory balance-sheet before you. I feel that we have placed our system, as a system of telegraphic communication, in a position that it would be very difficult to beat. There is scarcely any great commercial point in the world that we have not reached by telegraphy. We have not gone on by leaps and bounds with our dividend, but we have enormously strengthened and improved the value of our property by what we have done.

I hope the result will be that we have a system so very nearly completion that we shall look back on it with satisfaction, as having derived benefit from that particular progressive policy I have referred to.

I think I have now pretty well exhausted all my notes. There is a reference in the report to the bonus which we gave to our people employed in Egypt. If you throw your mind back to the last half-yearly meeting, you will remember there was a very strong expression of opinion and sympathy with our young men who were employed during the war. In fact, there was a resolution passed thanking them for their services. Now we felt, looking at the sacrifice they had made—looking at the losses many of them had sustained—(everything except what they had on their backs)—that in the midst of our prosperity, and having done very well for all parties, we thought it would be wrong to leave them out. Therefore we have given them it is not a large sum to each—a bonus that will satisfy them, and which will not in any way interfere with what you will receive. It will give them something more than a mere formal resolution, for it is a substantial acknowledgment from you of what they have gone through. It will also incite them to similar exertions in the future in your interests should occasion arise. Now, with these remarks, I beg to move,

"That the report and accounts of the directors to the 30th September, 1882, submitted to this meeting be, and they are hereby received and adopted."

The VICE-CHAIRMAN (the Marquis of Tweeddale): I beg to second that.

The CHAIRMAN: That has been moved by myself and seconded by the Marquis of Tweeddale, and if any gentleman in the room has any remark to make, I shall be very glad to answer the questions before I put the resolution to the meeting.

Mr. LANDELL: There is just one point I should like to touch upon. I see by the balance-sheet that there are debentures repayable this year to the amount of £232,000. I should be glad to know at what rate the directors will be able to replace those debentures. They were issued at 6 per cent., which was not an extravagant rate at the time, but as they mature I hope that we shall be able to replace them as they fall due at a less rate than they were formerly issued at.

Mr. WILLIAM ABBOTT: I see in one paragraph of the report that you intend to take a large proportion of the money necessary for these new cables from the reserve fund. I do hope that you will take an early opportunity to replace that money. It is clearly a capital charge that ought to be replaced. In the present flourishing condition of the Company our reserve fund is really not required. Not that I intend to take a gloomy view at all, but a time may come when it may be a very desirable fund to draw upon; and it was for the special purpose of an accident that that fund was created. I can see that if you sell any portion of the stocks you hold you can do so at a considerable premium, and I, therefore, commend you for the wisdom which you have displayed in making such an admirable selection as you have done.

You have referred to a special allowance having been made to the Egyptian staff. You made that payment to them on your own responsibility, but I dare say you come before us to endorse that act. I do not think there is any one shareholder in this room or on the list of the proprietors who would take exception to the course which you have adopted. I should like to go further. In my experience of companies I have never interfered with boards of directors as to what they do with regard to their staffs, as I consider it is for directors to take the full responsibility for what they do. But, at the same time, directors like sometimes to be fortified by the views of a meeting. I know the extraordinary work which was thrown on the London staff during that period of excitement and anxiety, from the effects of which the directors themselves were not free, and I think it would be very right on this occasion to go outside the principle of non-interference and express our opinion, conveying not merely thanks but something substantial to the London staff. So far from detracting from what the Egyptian staff have done, I would say that I think they have done wonderfully, and that it is to their zeal, foresight, and ability that you are indebted for this magnificent balance-sheet. At the same time, in addition to the vote of thanks passed to the staff in London, we should carry with it a substantial expression of our opinion in the form of a money bonus. I am not too old to remember the feeling of veneration that I had for the directors of the London and Westminster Bank when they proposed, after paying 10 per cent. to their proprietors, to give a bonus to their staff. I have no doubt of the good that it would be to adopt such a suggestion as that which I now recommend.

The CHAIRMAN: With regard to the debentures, I think I have always stated, more particularly twelve months ago, when we were discussing the question of finance, I was hopeful of dealing with that question. I may say, too, that I am hopeful to-day, as the Bank rate is going in the right direction.

Mr. ABBOTT: It is down to 4 per cent.

The CHAIRMAN: You may depend upon it that that matter will have our very careful study. We should have acted before this but for the high rate of interest prevailing. Had the Bank rate been at a low rate, we should, I believe, have been dealing with the debentures before now, but we are waiting for the proper time to deal with them. When it comes we shall look very carefully to getting our debentures placed at the lowest rate.

In regard to the remarks of Mr. Abbott, I entirely concur with him. I like to see a very fine substantial reserve fund. I am strongly in favour of it, and if we should take any portion from our reserve fund at any time, I hope it will be replaced. I have an idea that we ought to put £100,000 a year to the reserve fund, and we should get it up to a large sum in a short time in that way. If we can keep down capital expenditure, which I think it is very desirable to do, and carry out the necessary additions that are required by taking a little from the reserve fund, I think we meet the wishes generally of the shareholders. These are questions which always receive from us very serious attention, and on these occasions, when we give you a full and explicit account of all our doings, we are always glad to receive suggestions such as Mr. Abbott and the other gentleman have made. We have the very best information ourselves, but the more information we get the better. We are always prepared to receive it.

I am very much pleased at the expression of opinion, so marked as I gather

Digitized by Google

it to-day, from this meeting in favour of our staff. The staff have done their duty well and faithfully, and at the same time I am bound to say that those who have been controlling the staff have had no easy work. It was not only daily work when this crisis was going on—it was hourly work—night and morning, and constant and steady attention was required. The communications that were coming required immediate and prompt attention, and as an evidence of great enterprise I may mention that we actually chartered two ships during that great crisis, so that nothing should be wanting. We chartered them at very considerable expense. But you have had your return in a larger degree than what you paid for them. Telegraphy is not an ordinary business, but one requiring attention every hour of the day, and it does receive that attention from us. If not I should not be able to address you as I do to-day. I am, therefore, very much pleased at finding that the action of our staff has been appreciated, and you may depend upon it that the directors will give due attention to your views in this matter. The resolution I have now to put—

Mr. JOHN NEWTON: It does not seem that the salaries and wages have been much increased though your staff has been so hard at work. The expression of opinion of the meeting is that something extra should be given, that the extraordinary work of the past half year should be recognised, but I think that whenever the staff is extraordinarily pressed they should receive some special attention.

The CHAIRMAN: I quite understand the position and what you say, and I am very glad to see that you take the same view as Mr. Abbott does. You may depend upon it that we have a very good staff, and the staff know that they have very good employment, and they know the value of their employment as much as we do. It is encouraging when some appreciation of the staff is shown, and you may depend upon it that we who represent you will act in accordance with your views. Now, gentlemen, those in favour of the motion hold up their hands. To the contrary? Carried unanimously. The next duty that I have to perform is to move—

"That Lord Sackville Cecil, who now retires, be and is hereby re-elected a director of the Company."

Mr. G. G. NICOL: I beg to second it.

The resolution was put to the meeting, and carried unanimously.

Lord S. CECIL: I am very much obliged to you, and I hope I shall continue to deserve your confidence.

The CHAIRMAN: The next resolution is—

"That General Lord Alfred Paget, who now retires, be and is hereby re-elected a director of this Company."

Sir JAMES ANDERSON: I have much pleasure in seconding that.

The CHAIRMAN put it to the meeting, and declared it carried unanimously.

General Lord ALFRED PAGET: I beg to thank you also. I hope in the course of two or three months to be able to go out and see a good many of our officials in our Eastern districts and in the Mediterranean, where I went last year. It always does good when they see directors taking an active interest in the affairs of the Company.

A SHAREHOLDER: The next resolution on the agenda paper has reference to the election of auditors. With your permission I shall have much pleasure in moving—

"That Mr. Henry Dever and the firm of Messrs. Quilter, Ball, Crosbie, Glegg, and Welton be and they are hereby elected auditors of the Company for the current year with a joint remuneration of £100."

Mr. JOHN NEWTON: I second that.

The CHAIRMAN put it to the meeting, and declared it carried.

Mr. RIXON: I may say one word more. We have not spoken about the remuneration of the directors. Has not the time arrived when that may be increased?

The CHAIRMAN: That concludes the business.

Mr. ABBOTT: I presume that your modesty prevents your touching upon that subject, but I have not the slightest doubt that the time will come when a resolution such as that just foreshadowed will be received and adopted. I well remember in the early period of the Company's history—as I think I have said before—that there was no better abused man than yourself. The proposals that you brought forward for the extension of capital were met by counter resolutions, and the stormy scenes we had in connection with this Company ought to be well remembered. All the advice that you as a Board have given this Company has proved perfectly correct. I well remember the proposals as to the Black Sea line and the South African Company. Look at what those measures have resulted in. We were told that we were heaping up debentures. Well, look at the result. I have always maintained that a telegraph company, like a railway company, cannot stop still so long as the world moves on. I may here say I will undertake at the next meeting—now when we have dealt with the staff—I shall undertake to propose at the next meeting an increased remuneration to the Board. With these remarks I beg to move that you be thanked for what you have done for the shareholders at a time of extraordinary trial and anxiety.

A SHAREHOLDER seconded the motion, and

Mr. ABBOTT submitted it to the meeting.

Mr. MOORE: In speaking of this matter of the directors, I think it affords me a little opening to touch on a question not dealt with in the report—and one which could not well be, as not being one of figures, but as relating to the general working of the Company. I have listened to your speech with a great deal of interest, but there is a matter that some shareholders would like an explanation of. Our managing director, Sir James Anderson, is at the present moment the chairman of a news agency—the Exchange—and that company was started at the time when the Egyptian war was carried on ["Time, time"]. Sir James Anderson is competing with the best customers that you have in that way. I hope you will allow me to say these few words, as it will give you an opportunity of saying yes or no to them. It is a question for the shareholders' interests.

The CHAIRMAN (interposing): Let me ask you one question. Are you connected with the Central News?

Mr. MOORE: I am a journalist.

The CHAIRMAN: I want fair play in this. This is a question that will in all probability come before the courts. This meeting, therefore, is not the proper place to discuss it. I think it would be very improper to do so. I know perfectly well what you are going to arrive at.

Mr. MOORE: I think not.

The CHAIRMAN: I wish to say that I am as anxious as you are that this question, if you have a case at all—for I presume you are representing that—I am as anxious as you are that it should be inquired into, but let it be done at the proper place. This is not the place to do it. I am quite prepared to say that the imputations thrown on this Company from certain quarters we treat with the utmost contempt. We stand too high to feel in any degree such imputations. We have done the service in a way that it would be impossible to do it better. I speak generally, and the more the question is investigated the more will be seen the importance of our position. I speak with all proper respect for you in saying this. I will take care of this, that whatever there may be between the two companies—I do not care if there is one or a dozen companies—they shall all get fair play. That is all I have to say as chairman of the Company. I am perfectly prepared from what I know of the case to stand by the side of Sir James Anderson, and to vindicate him.

Mr. MOORE: May I ask one question? Is it true that our clerks acted as correspondents for the Exchange Company?

The CHAIRMAN: It is not true, I can answer that.

A SHAREHOLDER: I beg to move a cordial vote of thanks to the gentleman to whom we are so greatly indebted—Sir James Anderson. No man has served you better in this business in Egypt than Sir James Anderson, and every one present I am sure will join me in conveying a vote of thanks to him. When the time comes no one will be better able to defend himself in this matter than Sir James Anderson.

Major LESLIE: I second this resolution. I represent the largest interest in the Company. I am constantly watching its operations, for I represent over £100,000. I have no personal relations or interests with Sir James and the other directors, only those of business. I utterly disbelieve that anything wrong has been done by Sir James Anderson, or anything that an honourable gentleman might not do. I refuse to believe it. I have great pleasure in seconding the motion.

The CHAIRMAN put the motion, and declared it carried unanimously, with one exception—Mr. Moore.

Mr. WELLS (to Mr. Moore): What is your name?

Mr. MOORE: My name is Moore.

A SHAREHOLDER: Let us hear you no more.

Mr. MOORE: You will have me every time——

The CHAIRMAN: I am very much obliged to you for what you have said. I can assure you, as shareholders generally with myself, that we are entirely satisfied with the position we hold. It is not strictly pecuniary interests that we look to, but to the important work we have to perform, and the great national interests the Company serves. At the same time, I have always been an advocate for paying gentlemen well, and when the Company arrives at the position that it can pay very well, I shall be ready to agree to a proposal to increase our remuneration. At present we are very well satisfied.

Mr. WELLS (to Mr. Moore): What shares do you hold?

Mr. MOORE: You will find in your book.

Mr. WELLS: What is your initial?

Mr. MOORE: J.

The meeting then separated.

THE CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).

The twenty-third ordinary general meeting of the shareholders was held at the offices of the Company, No. 61, Old Broad-street, on Wednesday, the 31st January, Mr. Joaquin de Mancha, the chairman, presiding.

The SECRETARY (Mr. James Scott) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, will you have the report read first, or will you take it as read? [Voices: "Take it as read."] Well, gentlemen, the accounts have been before you for several days, and as we rather pride ourselves that our accounts are very clear and explicit, they do not require much explanation from me. You will see that our late chairman (Mr. Thomas Hughes) has resigned his position at the Board, and we regret his loss very much. The ability and experience that he had will rather cast me in the shade, but I can only say that I will do my best to conduct the business of the Company in the same way that it has been conducted, and if there should be any shortcomings, I must throw myself on your generosity to overlook anything that is not quite up to the mark [applause]. The accounts, as you will see, gentlemen, show that after providing for the Preference dividend of 10 per cent. we have been able to recommend that a dividend of 7 per cent. on the Ordinary shares shall be paid to you. I think, taking all things together, you must consider that satisfactory [applause]. We shall divide for the year 7½ per cent., and, looking at the accounts, you will see that besides doing that we have been able to place to the reserve fund the sum of £1,325 more. Some gentlemen may perhaps think that the reserve fund is getting too high, but for my own part I should like to see it much higher [applause]. The business of a telegraph company is so very uncertain, we are subject to so many casualties and unforeseen events, that I think the stronger the reserve fund is the more satisfactory it will be for the shareholders, and you may reckon that the dividend on the Ordinary shares will not be dimished so long as we have sufficient funds for any repairs which may have to be done. The business of the Company, I am happy to say, has been very prosperous during the year. We have earned nearly £5,000 more than we did in the previous year [applause], and I think, taking into account the little business that has been doing all over the world, we cannot complain, seeing that we have got a very substantial increase on our profits. I am sorry to say the cash does not come in in quite the same proportion as the increase in the number of telegrams. We have had nearly 5,000 messages more, and we generally reckon that every telegram produces nearly £1. In consequence, however, I suppose, of people being more experienced in telegraphing and in curtailing their messages, we have not increased so much in point of money as in the number of messages. At all events, I think we cannot complain of the want of success of the Company, and, with these few remarks, I will conclude by proposing "That the report of the directors and the accounts be received and adopted." If any of

Digitized by Google

the shareholders have any questions to ask I shall be happy to answer them to the best of my ability [applause].

Mr. ALEXANDER F. LOW seconded the resolution.

The resolution was then put and carried without comment.

The CHAIRMAN next proposed that a dividend of 7 per cent., free from income-tax, on the Ordinary shares be paid. The dividend warrants were all ready, and would be posted to-night, so that there would be no loss of time in their getting the dividend. He also proposed that 10 per cent., subject to income-tax, on the Preference shares should be paid at the same time.

Mr. LOW seconded the resolution, which was also agreed to *nem. con.*

The CHAIRMAN: Well, gentlemen, that is the whole of the business that you are called here to-day for.

Mr. GRIFFITHS: Mr. Chairman and gentlemen, I think we ought not to separate without placing upon record our appreciation of the services which had been rendered to this Company by Mr. Hughes who, we are glad, has received promotion, though we regret that we lose by what he has gained. He has been connected with the Company from the beginning. He is, undoubtedly, a man of considerable intelligence, clear and acute judgment, of comprehensive understanding, and of a most gentlemanly bearing. He has presided over us in times of prosperity and in times of adversity, and I think we may say, without dispute, we have been fortunate in having at our head a gentleman who had a legal training, and who was enabled to bring those qualities to the service of the Company with which he was connected. Our Company, as you are aware, has extensive foreign business transactions, and the knowledge of international law which he possessed must have considerably facilitated the transaction of the business with the Spanish Government and the Island of Cuba. You yourselves have witnessed the way in which he presided, and I think you must acknowledge that he conducted the proceedings with fairness, that the discussions were complete, and the information was given readily and kindly [applause]. Of course, as I said before, that which is his gain is to a great extent our loss. The speaker continued that by that remark he did not cast the least reflection on the present directors. They were gentlemen of experience, but it is always a bad thing for a company when the leading man—that is, the chairman—leaves it. He thought, therefore, they would agree with him that it was a proper thing that they should express their sense of the benefit which the Company had received from his presidency, and that they should also express their hope that those great qualities which had been of such service to them would, hereafter, be of service to others in a wider sphere, and he would not only have the satisfaction of remembering that he had been successful as chairman of a telegraph company, but also as one of the members of the judicial establishment of this great country [applause].

Mr. NEWTON said he had great pleasure in seconding the proposition moved by Mr. Griffiths.

Some little discussion then ensued amongst the shareholders as to the desirability of adding some tangible mark of the shareholders' appreciation. The result was that the shareholders empowered the Board to expend the sum of 100 guineas in the purchase of a piece of plate to be presented to Mr. Hughes.

A vote of thanks to the chairman and directors closed the proceedings.

THE ELECTRO-AMALGAMATOR COMPANY (LIMITED).

The first general (statutory) meeting of the shareholders of this Company was held at the Terminus Hotel, adjoining London Bridge Station, on the 26th ult., under the presidency of Mr. W. J. Tanner.

The CHAIRMAN having described the amount of work which had been done since the formation of the Company in getting the business in order for practically treating quantities of ore, by erecting a gas engine, crushing machine, riffle table, dynamo machine, and by transacting various other necessary matters, said: I will now, gentlemen, say a few words as to the patent itself. When the Company was formed we had a conference with Mr. Aston, Q.C., in order to settle the final specification, and as it was vacation time we were fortunate enough in having an unusually long consultation, and, after going into the matter fully, Mr. Aston was perfectly satisfied as to the validity of the patent, subject to its not having been anticipated—a matter to which we have given our full attention by having the Patent Office thoroughly searched. One of the chief charms about this patent is its simplicity, which consists of the application of well known agencies for a particular purpose, and in a particular manner, which can be adopted at a remarkably small cost. From a scientific point of view the invention must carry out the objects for which it is intended, and from the scraps of knowledge I have been able to patch together I think I shall be able to show you some strong evidence in support of the principle. I must remind you that I am neither an electrician, chemist, nor a mechanic, and, therefore, my remarks and opinions must be taken for what they are worth; but it seems to me there are so many diversities of opinion and so many theories about the properties and effect of electricity, that it is impossible to arrive at any conclusion that is altogether satisfactory. As far as I understand the matter, it is simply this. Let it be given as an admitted fact that mercury, when fresh and clean, readily absorbs gold and silver when they come in contact with it. It must be also allowed that the presence of antimony, arsenic, mundic, titanic sand, and various other substances, sicken or coat over the mercury, and so prevent gold and silver from adhering or amalgamating with it; and as there are vast quantities of ores with gold and silver all over the world that contain some one or more of these minerals, which are destructive to the mercury, it is obvious that any system that can be invented which will keep the mercury clean and bright, and always ready to take in the gold and silver, must be of immense value. That Barker's electro-amalgamator carries out this requirement is conclusively proved, both in theory and practice. Now, in the case of this invention the negative pole is applied to the mercury, and as mercury is a very good conductor of electricity, it, in fact, becomes our negative pole or cathode. The positive poles are strips or wires of copper or some good conductor, which are laid over but not touching the mercury. Just as the electric light is formed by making a break in the circuit and introducing carbon points, so our circuit is broken and joined, so to speak, by the agency of water; the water becomes chemically changed, and, of course, if chemical matters are introduced into this water, various other changes and modifications will take place. The first thing that strikes our notice on the application of the electricity is the immediate disappearance of any scum on the top of the mercury—it becomes as bright as it possibly can be. As the various substances that usually sicken it come under the influence of the electricity, they are immediately rejected, and the surface is kept constantly bright and in the fittest state for absorbing gold. This is conclusively proved by artificially sickening the mercury; directly the electricity is applied the matter that sickened the mercury is ejected, and the tiny globules into which it has been beaten run together, presenting a bright and uniform surface. Now, gentlemen, I think it logically follows, if the electricity will purify the mercury when sick, it will *a fortiori* prevent it from getting sick when pure. The invention in this respect is of enormous value, but I contend that the keeping the mercury clean is not the only point gained, and I think it will be admitted that the electricity induces the contact between the gold and silver and the mercury. In this way certain minerals are driven by diamagnetic action from the positive to the negative pole, and among them gold and silver. Now, as the crushed ore passes over the mercury it is conveyed by means of the water between the negative and positive poles, and each gold particle becomes an electrode, with the obvious effect that it is impelled from the positive to the negative pole. In our case the negative pole is clean mercury, which readily absorbs the gold and silver particles, so we have not only the natural gravitation of the gold but the diamagnetic force, which, I think, possibly precipitates the gold in the mercury, leaving it clean at the top. Why, it may be asked, are not other metals like iron and copper equally by the same influence driven to the mercury? So I say they are, but as mercury has no affinity for these metals they are kept moving over the mercury, getting as far as possible from their enemy, the positive pole, until they are thankfully washed away by the water. In the case of sulphurets the action is different. They become decomposed, and thus liberate the gold, and instead of depositing themselves on the negative pole and sickening it, they judiciously avoid it, and go to the positive pole, attracted by the copper, and get formed into sulphate of copper. It is more than satisfactory to find these theories are practically proved true, for if you refer to pages 10 and 11 on our pamphlet which has just been issued, you will see that out of some sand given to us from one of the Indian mines, assaying 2oz. 13dwts. to the ton, by the Electro-Amalgamator process we have taken out 2oz. 11dwts. Now the analysis of this sand shows nearly 61 per cent. of titanic acid and iron, so there can be no wonder that with the ordinary process the gold could not be extracted. I understand there are thousands of tons of this sand, and the result we have shown with our treatment is worth £50,000 a year to the owners of this property. This is not an isolated instance, but from the information I can gather it forms an example of the rule, and by no means an exception. Indeed, I can assure you, gentlemen, I am bewildered at the possible value to the world at large of this invention. From all quarters I hear of the thousands of tons of gold and silver ores that are unworkable from the presence of the obstacles which this invention removes. There are generally two values to saleable property, first, its intrinsic value, and secondly, what you can get for it. Now, this invention being all that is claimed for it, its intrinsic value is many millions, but this we cannot expect to get, except, perhaps, indirectly. A person came to me some months ago with the view of purchasing one of the patents. I told him we were not ready, and before the invention was made public we wished to prove it and perfect it on a commercial scale. He said, "You take my advice, if it is really good, and will bear looking into, do not be in a hurry to part with it; if it is worth nothing, sell it at once." Now, there is a sublime simplicity about this system of financing that, I fear, is more remarkable for its success than its morality. We, as directors of this Company, have not only your interests to protect, but our names, and, therefore, we must take personal care that any patent we offer for sale will bear looking into, as there is no consideration sufficiently large to induce us to foist anything upon the public unless we are clearly satisfied it is all we claim for it. I do not see that we attack any vested interests; on the contrary, the vast amount of capital invested in gold and silver mines that do not pay will now return profits, and those mines that do pay will pay more. All we require now is gradual publicity, and in this, I am sure, you will help us. I say gradual, as, owing to the small space at the works, there is not room to have a large assemblage at a time, but both scientific and practical men who have seen the invention have always expressed themselves as strongly impressed with its value. We must, however, make it generally appreciated before we can expect to sell any of the patents at anything like their actual worth. I am very much obliged for the kind way in which you have listened to my remarks, and I shall be happy to answer any questions to the best of my ability, but I am not prepared to join issue where any scientific principles are involved.

A discussion followed, and in reply to questions and observations,

The CHAIRMAN stated that they had no negotiations on foot at the present time for the sale of any of the patents, as it had only been within the last few days that they had attempted to make the matter public, but they were ready to commence negotiations almost immediately. They had been in correspondence with several of the Indian mining companies. Several of the directors of those companies had called on them, and had expressed very much interest in the patent, and having the patent in hand. India would be their first field. The capital subscribed in cash had been £5,000, of which £2,500 had been paid up. The patentee had received £1,000. There was, roughly, about £500 or £600 at their bankers. The remaining £800 or £900 had been expended in rent, a dynamo machine, and a gas engine. In all probability the whole of the capital would have to be called up. [A VOICE: I hope so.] The amount of profit would be distributed in proportion to the amount paid up.

Two or three shareholders expressed their opinion that the profit should be distributed per share, not according to the amount paid up.

The CHAIRMAN, continuing, stated that the point would be made perfectly clear to the shareholders before anything was decided. His own opinion, however, was that in dividing profits the distribution should be made according to the amount paid up. As he had said, the capital would probably all be called up. It would be required for obtaining the patents.

Digitized by Google

They had bought half the patents from Mr. Barker on these terms, excepting the American, which was left in abeyance for the time, and excepting the New Zealand patent altogether, but the whole of the rest of the patents all over the world. They had paid for their half £4,000 in shares and £1,200 in cash, and when the American patent was received they would pay another £3,000 in shares and £1,800 in cash. Altogether that made £10,000 which the patentee would receive—£7,000 in fully paid shares, and £3,000 in cash. The capital of the company was £20,000, of which £5,000 had been offered for subscription, which had been more than applied for. He could not say that they were yet in a position to enter into negotiations for the sale of a patent. Their policy to a great extent was to build up their foundation sufficiently strong and so secure that they might be able to sell. They had fourteen years for the patents to run. He felt that if they were to force the sale of any of their patents they would be greatly prejudiced. They had received the patents for France, India, Canada, and Portugal. Those for Spain, Germany, and United States were going through, and that for South Australia they could not yet have got. As to Chili, Peru, and the Brazils, they had special agents who were taking the patents through.

The following resolution, on the motion of Mr. H. B. HEWITT, seconded by Mr. C. RANDOLPH, was then passed with one dissentient:—"That the remuneration of the directors for the ensuing year be 5 per cent. of the amount of profits actually divided during that period."

[We are requested to state that:—"Since the meeting the directors have received the results of some washing of ore from, perhaps, the richest gold mine in the world, the quartz from which shows by assay 44oz. gold to the ton; but, owing to the refractory nature of the ore, sufficient gold in paying quantities has not yet been obtained. Mr. Fred Claudet's assay shows that Mr. Barker's process has extracted 38oz. out of the 44, or about £130 per ton."]

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION (LIMITED).

The poll demanded at the meeting of this Company (held on the 23rd ult.) was taken last Tuesday, between two and five o'clock, at the City Terminus Hotel. It will be remembered that at the meeting on the 23rd ult. the chairman (Sir H. W. Tyler, M.P.) moved the adoption of the report, and that Mr. Gillitt subsequently brought forward an amendment for the appointment of a committee of the shareholders to inquire into and report upon the position and conduct of the affairs of the Corporation. On the show of hands there was a decided majority in favour of the amendment, when a poll was demanded on behalf of the directors. At the close of the poll,

Sir H. W. TYLER, M.P., moved the further adjournment of the meeting to Monday next, at the City Terminus Hotel, at twelve o'clock, "for the purpose of receiving the report of the scrutineers and the declaration of the poll and of continuing and concluding the business."

Mr. LANE-FOX seconded the motion, which was carried.

Mr. JOSEPH BRAITHWAITE then observed that it might be interesting to the shareholders to know that on the face of it the poll showed a large majority in favour of the directors.

It may be added that the remaining business after the disposal of the report is the confirmation of the appointment as a director of Lord C. J. Hamilton, M.P., in the place of Mr. Nettlefold resigned, and the re-election of the retiring directors and auditor. A resolution will also be proposed, enabling a further issue of 700 fully paid £10 shares to Mr. C. F. Brush or his nominees "in compromise of the agreements for the purchase of the Russian and Belgian patents."

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).

Report of the directors to the ordinary general half-yearly meeting of the proprietors, to be held at the City Terminus Hotel, Cannon-street, London, on Friday, the 9th inst. at noon. The total receipts from the 1st July to the 31st December, 1882, including a balance of £5,583 19s. 9d. brought forward from the last account, amount to £262,534 0s. 2d. The traffic receipts show an increase of £36,026, as compared with the corresponding period of last year. The total expenses of the half year, including repair of cables, income-tax, &c., as shown by the revenue account, amount to £58,084 18s. 8d. The directors, under the powers conferred upon them by the Articles of Association, have, before declaring the net profits, set apart the sum of £75,000 to the renewal fund, leaving an available balance of £129,449 1s. 6d. Interim dividends of 15s. per cent. on the Ordinary Stock and 30s. per cent. on the Preferred Ordinary Stock, free of income-tax, were paid on the 1st November last, absorbing £52,500, leaving a balance of £76,949 1s. 6d., out of which the directors recommend the proprietors to declare final dividends, free of income-tax, of £1 per cent. on the Ordinary Stock, and £2 per cent. on the Preferred Ordinary Stock, amounting to £70,000, and making a total distribution for the year ended the 31st December, 1882, of 2¾ per cent. upon the Ordinary Stock, and 5½ per cent. upon the Preferred Ordinary Stock, leaving a balance of £6,949 1s. 6d. to be carried forward to the next account. The Brest-St. Pierre cable, laid in 1869, which was broken in mid-ocean on March 18 last, was successfully repaired on Sept. 20. Four faults were removed, in depths varying from 400 to 2,000 fathoms of water. The ship employed upon the repairs of this cable in deep water was the Telegraph Construction and Maintenance Company's steamship "Scotia," which was engaged upon the work for more than four months, at a cost, including new cable used, of upwards of £90,000; the directors consider that the expenditure of so large a sum of money is amply justified by the results, the electrical condition of the cable being now perfect. The cost of these repairs has been charged to the renewal fund. The Company's repairing steamship "Minia" has been engaged during the half year in repairing a fault in the Brest-St. Pierre cable, which occurred on the 25th July, at a distance of 200 miles from St. Pierre, and also in repairing the St. Pierre-Duxbury cable, which was broken on the 26th September. The Company's system of cables and land lines on both sides the Atlantic is now in good working order and condition. The tariff of 2s. per word, which was resumed on the 22nd May last, upon the execution of the joint purse agreement with the American Telegraph and Cable Co., has proved satisfactory. Although no competing Atlantic cable schemes have actually been established within the last half year, two were before the public for several months. The eight cables now at work are more than enough to meet every possible requirement, and the directors trust that by keeping up the present prompt and efficient service, at the moderate rates now charged, the public will be deterred from subscribing money to new cable enterprises, which cannot, under any circumstances, pay a dividend equivalent to the great risks incurred. The directors regret to announce that Mr. L. M. Rate has resigned his seat at the Board. His long experience in connection with Atlantic cables, as chairman of the Atlantic Telegraph Company and director of this Company, rendered his services of great value to the Board. Mr. William S. Cunard has been chosen to fill the vacancy caused by Mr. Rate's resignation. In accordance with the Articles of Association, two directors of the Company, the Marquis of Tweeddale and Mr. Cyrus W. Field, retire at this meeting, and, being eligible, offer themselves for re-election. Mr. Joshua Dean and Mr. Francis Glass, the auditors, also retire, and offer themselves for re-election.

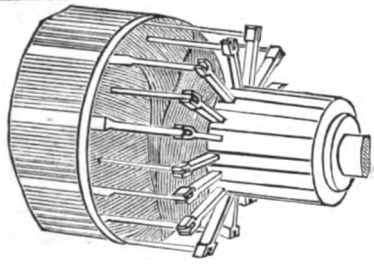
RECENT INVENTIONS.

ABSTRACT OF SPECIFICATIONS.

2694. IMPROVEMENTS IN DYNAMO OR MAGNETO-ELECTRIC MACHINES, *W. R. Lake, London.—8th June*, 1882.—(*A communication from E. Weston, Newark, New Jersey, U.S.*) 6*d*.

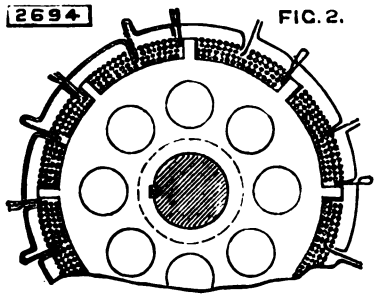
This relates to the winding of the armatures of the inventor's dynamo machines, and the object is to save time and labour, and, as far as the first part of the patent is concerned, to supply cur-

2694 FIG. 1



rents of high electromotive force. The method of winding is shown in Figs. 1 and 2. The claim is for "an armature wound with two systems of coils in diametrically separate divisions, the

2694 FIG. 2.

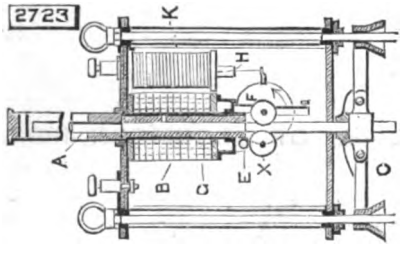


divisions of one system being alternately under and over those of the other system, and the said divisions being looped together and connected to the commutator." The other part of the patent relates to an armature wound so as to produce currents of great quantity.

2723. IMPROVEMENTS IN ELECTRIC LAMPS, *C. G. Gümpel, Leicester-square.—9th June*, 1882. 6*d*.

This relates to an arc lamp, the arc being regulated by two electro-magnets, one in the main the other in a shunt circuit. The invention will be better understood by the accompanying illustration. The upper carbon is fixed to a guided holder C, attached to a rod A passing through solenoid B, and counterbalanced by a weight connected to it by cords passing over pulleys. When the upper and lower carbons (the lower one being stationary) are in contact and the lamp

2723

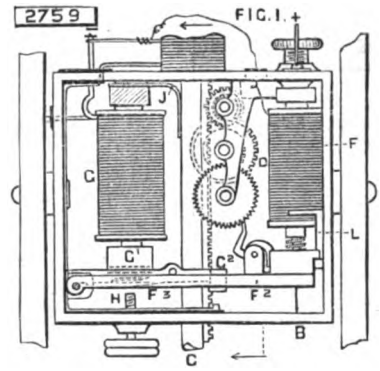


in circuit, coil B, of low resistance, becomes energised; core G is then attracted upward, and moving the bell crank E causes roller X to press against rod A, so that the latter is gripped between X and F, and by the continued ascent of the core the arc is struck. When the arc gets too long and its resistance great, the current passes through shunt coil K of high resistance. Its core H is then drawn upwards, and its pawl clamps the rim of wheel W, turning it in the direction of the arrow and causing the upper carbon to descend, so as to adjust the arc.

2759. IMPROVEMENTS IN ELECTRIC LAMPS, *H. H. Lake, London.—12th June*, 1882.—(*A communication from R. R. Moffatt, Brooklyn, New York.*) 6*d*.

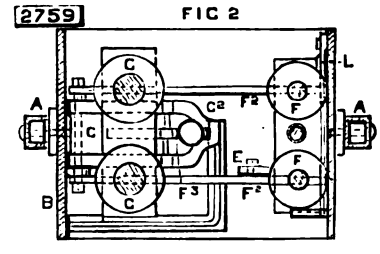
This relates to the regulation of arc lamps and to a means for cutting the lamps out of circuit. Referring to our illustrations, when electro-magnet G—Fig. 1—attracts its armature, G^1, the catch F^3 lifts the carbon-supporting rod C so as to establish the arc. G^1 is mounted on two levers, G^2, which are arranged between the levers F^2, and similarly pivotted to box B—see Fig. 2. These levers, G^2, are united at their free ends, and carbon-rod, C, passes between them. The

2759 FIG. 1.



catch F^3 consists of a bell-crank lever pivotted at the end of one arm to a rod which extends between the levers F^2 so that its angular position can act on C. The other arm is actuated by a spring so that the angular portion will be forced against C, when the arc is established and the electro-magnet G demagnetised, its armature descends with levers F^2, the outer arm of the catch stops against H, and on the further descent of the armature and levers the catch releases C and the upper carbon descends into contact with the lower. A derived circuit extends from box B to metal lever L, thence through a

2759 FIG 2



small contact piece to the electro-magnet, and thence through the insulating material in B to the wire. The armature of F extends between the two shoulders of L and shifts it so as to impinge on the before-mentioned contact piece or be removed therefrom. The armature, however, can move sufficiently far to cause pawl E to operate the ratchet wheel and feed the carbon downwards before it shifts L, so as to break the shunt circuit. When this is broken the armature descends and shifts L so as to re-establish the shunt, and if the arc be still too great the operation will be repeated.

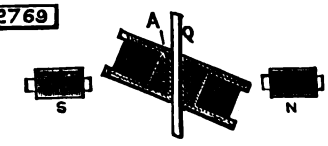
2752. IMPROVEMENTS IN THE CONSTRUCTION OF ELECTRIC LAMPS, &c., *J. Lane, Fulham.—12th June*, 1882. 6*d*.

This relates to incandescent lamps. Instead of mounting his filaments in the usual way the inventor fits them in a special plug, and inserts this into the neck of a glass globe and seals it there. A passage in this plug is utilised to produce a vacuum or to introduce non-combustible gases, and is then closed with sealing material.

2769. IMPROVEMENTS IN DYNAMO-ELECTRIC MACHINES, *J. Imray, Chancery-lane.—13th June*, 1882.—(*A communication from P. Jablochkoff, Paris.*) 6*d*.

This relates to the construction of dynamo-electric machines, the leading feature of which is the obliquity of the axis of rotation to the magnetic field as the axis of the earth is inclined to the plane of the ecliptic. The illustration represents a simple form of the machine. A bobbin, A, having cheeks of soft iron, and wound

2769

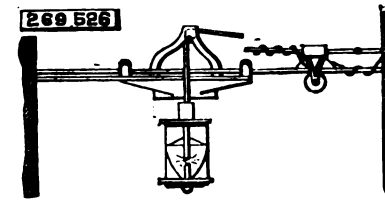


with a coil of insulated wire, is fixed obliquely upon an axis, O, and revolves between the poles of two electro-magnets, N and S. In each revolution the edges of the cheeks are presented alternately to N and S, as shown.

269,526. APPARATUS FOR SUSPENDING, RAISING, AND LOWERING ELECTRIC LAMPS, *Charles C. Jennings, Buffalo, N.Y.—Filed May 4th*, 1882.

Claim.—An apparatus for suspending, raising and lowering electric lamps, consisting substantially of supporting cables secured at their ends to the walls of a building or room, a carriage having arms provided with pulleys adapted to travel upon the supporting cables, and insulated brackets or hangers secured thereto, also provided with pulleys for the reception of the lamp-supporting cables, a cross arm having at each end

269,526

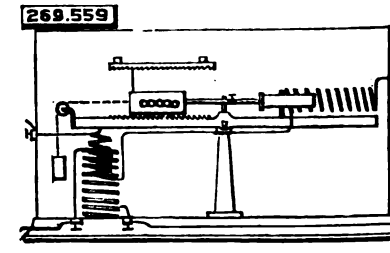


thereof a grooved pulley, pivotted to an insulated bracket or hanger to adapt the cross-beam to travel upon the carriage-supporting cables, supporting cables for the electric lamp, secured rigidly to the crossbeam and passing over the insulated pulleys upon the carriage to the lamp suspended below such carriage, and conducting wires connecting the positive and negative wires of the circuit with the supporting cables and the insulated pulleys of the crossbeam with the lamp-suspending cables, all combined and operating substantially as shown and described.

269,559. ELECTRIC-CURRENT METER, *Alex. Bernstein, Boston, Mass.—Filed October 4th*, 1882.

Claim.—(1) A current-meter composed of a scale beam, of a movable and counterbalanced registering device at one end of the beam, and of a fixed coil and a sliding iron core connected to the registering device at the other end of the beam, of a coil suspended below the end of the beam, carrying the register and placed in an auxiliary circuit with the coil at the other end of

269,559



the beam, and of a fixed coil of larger diameter and surrounding the suspended coil, and being placed into the main circuit, substantially as set forth. (2) The combination of a scale beam carrying a movable and counterbalanced registering device upon one arm, a coil and sliding core upon the other arm, a coil suspended from the arm carrying the register, a fixed coil surrounding the suspended coil, and a suitable stop mechanism, whereby the register is stopped when the equilibrium of the parts takes place, substantially as and for the purpose set forth.

Digitized by Google

SLIP

PARA.—The cable between Para and Maranham is again interrupted.

TURKEY.—The cable between Constantinople and Odessa is interrupted.

TELEGRAPHY IN PARIS.—The pneumatic system of despatching telegrams in Paris is to be largely extended after the 1st of April next.

CANADIAN TELEGRAPHS.—The Government telegraph line between Winnipeg and Regina is now in good working order. —*Colonies and India.*

THE HAMMOND COMPANY.—The Hon. Sidney Carr Glynn, M.P., has joined the board of the Hammond Electric Light and Power Supply Company.

THE CARCEL.—It may be of use to some of our readers to be reminded that the "carcel," or photometric standard in use in Paris, is equivalent to 9·6 English and 8·7 German candles.

EASTERN EXTENSION TELEGRAPH COMPANY.—The traffic receipts of this company for the month of January, 1883, amounted to £32,822, and to £33,129 for the corresponding period of 1882.

AMERICAN LAND LINES.—A telegram from Philadelphia, dated February 5, stated that a heavy storm, which had raged in the west during the previous week, had caused great destruction of telegraph lines.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended 31st January are £2,551, as compared with £2,851 in the corresponding period of 1882.

THE LIGHTING OF HOLBORN-VIADUCT.—The Edison Company have received permission from the Commissioners of Sewers to continue the lighting of Holborn-viaduct by their system for one year from the 24th ult.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company for January, 1883, amounted to £18,240, against £17,110 for the corresponding month of 1882, and £17,352 for the same month of 1881.

TUNSTALL.—This Staffordshire town is quarrelling with its purveyors of gas—the British Gaslight Company. The present charge is 3s. 6d. per 1,000 cubic feet, whilst the townsfolk think it should not be more than 2s. 6d.

FAILURE.—A recent *Gazette* announces that the first meeting of the creditors of Edward Penty, electro-plater, of 79, New Briggate, Leeds, will be held at the office of Mr. W. Wells, 16, Cookridge-street, Leeds, on the 13th inst., at 2 p.m.

INDIA RUBBER, GUTTA PERCHA, &c., COMPANY.—The nineteenth ordinary general meeting of this company will be held at the City Terminus Hotel, Cannon-street, E.C., on Tuesday next, at 12 o'clock noon. The report of the directors will be found in another column.

THE TELEGRAPH CONTROVERSY IN AMERICA.—A telegram from New York, dated February 7, says:—"The contest between the Western Union and the Mutual Union Telegraph Companies has been settled, the Western Union having agreed to lease the Mutual Union's lines."

VIENNA ELEVATED RAILWAY.—A concession has been granted by the Austrian Emperor for the construction of this long-talked-of railway. It is said that it will be constructed by an association formed by the Messrs. Fogerty, of Middlesbrough. Electromotors are to be used on it.

MORSE SLIP.—The English Post Office has just issued an order that in future the Morse and Wheatstone slips need not be preserved but, after being transcribed, are to be treated as waste paper. By this order the last vestige of a "record" in the British postal telegraph system is done away with.

POST OFFICE TELEGRAPHS.—An open competition for admission to the Post Office (Female) School of Telegraphy (age 14-18) will be held in London on the 26th February. Particulars and the necessary form of application can be had of the Secretary, Civil Service Commission, London, S.W.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY. —The directors of this company propose (subject to the audit of the accounts) paying a dividend of 15 per cent. (£1 16s. per share), in addition to the *ad interim* dividend of 5 per cent. already paid, making 20 per cent. for the year 1882.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of January was 2,953, estimated to produce £2,800, against 3,029 messages, producing £3,021, in the corresponding month of last year. The traffic receipts for the month of October, estimated at £2,000, realised £1,986.

TELEPHONIC COMMUNICATION WITH LIGHTHOUSES.—Mr. Chamberlain was asked at Swansea last Friday whether the Government would assist the establishment of a telephone wire between Lundy Island and the mainland. It is understood that Lloyd's have now determined to erect one within six months, provided they can obtain a subsidy of £600 a year from merchants and others on the Channel.

THE LIGHTING OF BATH.—The Town Council of Bath have awoke to the fact that the present lighting of the streets is "discreditable." To improve it they are going to substitute 6ft. for 4ft. burners, and introduce large gas lamps at certain points, and for this they are going to pay £57 more per annum than at present. The town council are by no means unfavourable to electric lighting.

A CHINESE TELEGRAM.—Among the Sovereigns who sent their congratulations to the Crown Prince and Crown Princess of Germany upon the occasion of their Silver Wedding was the Emperor of China. His telegram, which was in Chinese, was despatched from the Imperial Palace, Pekin, to Berlin, on the 25th ult. This is said to be the first telegram sent by the Chinese Sovereign to a European Prince.

THE SANITAS COMPANY.—The report of the directors of this company for 1882 states that the sales amounted to £11,443, as against £8,580 for 1881. They recommend a dividend of 5 per cent. for the year. The report further states that Sanitas disinfectants have been supplied to upwards of 600 corporations, railway, and other companies, &c., and that the company have been appointed contractors to H.M. Admiralty.

ELECTRIC LIGHTING IN BUDAPEST.—Electric lighting is progressing in this gay Hungarian town. We hear that Herren Ganz and Co. are to light up the National Theatre by means of 1,000 Swan lamps; that they are already fitting up 200 similar lamps in a corn mill there; and that the Café Steenassger, on the Corso, is lighted by means of lamps, the invention of Herr Zipernowsky, whose patronymic does not sound Hungarian.

NEW TELEGRAPH LINE IN CHINA.—A telegram to the *Daily News* of last Saturday stated that the Chinese representative at St. Petersburg had notified the Russian Government of the readiness of the Chinese Government to undertake the expense of establishing telegraphic communication

Digitized by Google

between Pekin and Kiachta. A subsequent telegram from *The Times'* St. Petersburg correspondent, however, stated that this was untrue.

THE COST OF ELECTRIC LIGHTING.—Champagne has not yet been sold for the price of beer, says the *Engineer*, but there can be no doubt that money is made by champagne growers, and there is good reason to believe that the demand for it is practically unlimited. We may regard electric lighting, as representing champagne, while gas stands for beer, and feel confident that the public will willingly use the former, even though the price should be higher than gas.

A NEW MEDICAL BATTERY.—A handy little battery, which the proprietors call the medical constant current electric generator, has just been introduced from America, and is now on view at 38, Lombard-street. It is said to be the invention of Mr. Hopkins, the editor of the *Scientific American*, and consists of a zinc and copper plate, separated by bibulous paper, the whole enclosed in a small ebonite box not much bigger than a card case, and can, therefore, be carried in the pocket or placed under the pillow. Convenient electrodes are attached for application to the body.

ELECTRIC RAILWAYS.—Owing to the sudden cessation of Court festivities at Berlin, consequent on the death of the Emperor William's brother, His Majesty's physicians have been somewhat at a loss how to provide suitable recreation for him. A happy thought seems to have suddenly occurred to them, however, viz., that of interesting scientific lectures. No sooner said than done, and accordingly the first of a series of such lectures was given before the Emperor and other members of the royal family by Dr. Werner Siemens a few days ago. His subject was electric railways in general, and the elevated electric railway with which he hopes to provide Berlin, in particular. His audience are said to have listened very attentively.

EXTRACTING GOLD.—Mr. R. Barker has patented a process for extracting gold from its ore, by causing it to be washed by a stream of water over an inclined table, in which are placed at intervals "riffles," or baths of mercury. The mercury is connected with the negative wire of a dynamo machine (Elmore's has been used up to the present), and the positive wire is lead to the water. By this means it is found that the mercury readily seizes on and holds the particles of gold, and never "sickens," as has hitherto been the case. The patent has been taken up by the Electro-Amalgamator Company, of Tower-chambers, Moorgate-street, E.C., who have erected experimental works near London Bridge, where the process was shown in operation recently.

INTERNATIONAL ELECTRICAL EXHIBITION, VIENNA.—We stated in a recent note that an International Electrical Exhibition will be held in Vienna, under the patronage of the Austro-Hungarian Government, in the months of August, September, and October next. At the request of the Austrian Minister of Commerce, and of the Managing Committee of the Exhibition, the Council of the Society of Telegraph Engineers have appointed a committee to receive applications for space from British exhibitors, and for promoting generally the formation of a British section. Application should be made as early as possible, and should be addressed to the Secretary of the Society of Telegraph Engineers and of Electricians, 4, The Sanctuary, Westminster, S.W.

ORNAMENTAL ELECTRIC LIGHTING.—An ornamental design in the shape of a monogram composed of Swan incandescent lamps has just been completed for Mr. Vanderweyde's photographic studio in Regent-street, W. The monogram is in the shape of a V superimposed on a W, the V being marked out by lamps having ground glass globes, and the W by lamps having plain globes. The current is derived from an A Gramme dynamo, driven by an 8 horse-power Otto gas engine, which Mr. Vanderweyde has for some time had in use. Forty lamps altogether are employed. The design was executed, and the lamps supplied, by Messrs. Laing, White, and Wharton, of Holborn-viaduct, E.C. The effect is said to be very good, and we do not doubt that other people will follow Mr. Vanderweyde's example.

A FAILURE OF GAS.—On the evening of Friday, the 2nd inst., a large part of the town of Halifax was suddenly deprived of light owing to a failure in the gas supply. The breakdown is attributed to water having got into one of the mains. Many mills and factories had to stop working, the railway stations were left in darkness, and generally things were uncomfortable in Halifax on Friday evening. Seeing what a vast amount is made by the journals representing the gas interest out of the occasional failures or breakdowns which occur in electric lighting, we think we may as well draw attention to the fact that gas is by no means infallible, even in a large town, where everything should be in apple-pie order. If we were to refer to every little breakdown in gas lighting in small towns and out-of-the-way places, we should have little room for other matters.

ELECTRIC LIGHTING IN HOLLAND. — Our Amsterdam correspondent sends us the following information:—The Nederlandsche Electriciteit-Maatschappij, who are sole agents for the Edison system in the Netherlands, have fitted up 30 lamps in the factory of Mr. C. W. Schonebaum, at Groningen. A chandelier, fitted with 12 A lamps, does duty in the office, and is supplied with a regulator, so that any intensity of light can be used. A larger installation has been made in a refinery known as the Westersuikerrafenadenij, where two Edison K dynamos generate current for 380 sixteen-candle lamps. The work in both cases was successfully carried out under the superintendence of Mr. H. C. Van Mens, engineer to the Nederlandsche Company. We may add that it is hoped that the Edison system will be employed to light the new theatre which is to be opened in Amsterdam this year.

PRESENTATION TO A TELEGRAPH SUPERINTENDENT.—From the colums of the *Daily Gleaner*, of Kingston, Jamaica, we learn that the energy and ability displayed by Mr. H. C. Wilson, superintendent of inland telegraphs in Jamaica, in establishing telegraphic communication throughout that island, have been recognised by the Jamaica staff. In December last Mr. Wilson was presented with a valuable gold watch on behalf of the whole staff in recognition of his services. On one side of the case are Mr. Wilson's initials, and on the other a gauntleted hand grasping a sheaf of lightning flashes, and the letters "K.N.," which is the Kingston "call." Inside the case is the inscription, "Presented to H. C. Wilson, Superintendent Government Telegraphs, Jamaica, by the entire Staff, 1882." We also learn from the *Gleaner* that Mr. Wilson rendered valuable help during the late disastrous fire at Kingston.

ELECTRIC LIGHTING FOR THE HOUSE OF COMMONS.—The Edison system of incandescent lighting is to be introduced into the House of Commons, so far as the corridors and passages are concerned. The Edison lamp will not, however, be used for lighting the House itself, as the gas has been found to answer all the requirements of the members and officers of the House. In many of the corridors and passages, especially those leading to the conference room, the tea room, and the library, the gas lights have been found rather ineffective

Digitized by Google

so much so that where flights of stone steps had to be descended there was a certain danger of stumbling to persons with poor eyesight. In addition, the long series of stone steps by which ascent is made to the Reporters' Gallery has been, under the gas system, miserably lighted. All these defects will, it is hoped, be wholly remedied by the introduction of the Edison incandescent lamp.

Electric Lighting at Cardiff.—Cardiff Castle, the residence of the Marquess of Bute, has been lighted by means of Swan incandescent lamps. On the occasion of a dinner given by the marquess last week in honour of the inauguration of the work of constructing a new dock at Cardiff, the banqueting hall was entirely lighted by their means, and the effect is spoken of as magnificent. The library and grand staircase are also lighted by Swan lamps, and we venture to think that the increased life thereby guaranteed to the noble marquess's books will render the lamps a permanent feature in his library. The work was carried out for the Swan United Electric Light Company by Mr. W. H. Massey, whose name will be familiar to our readers as having done some excellent work in Cardiff and elsewhere before. The new dock works will be carried on by night as well as day, the contractors, Messrs. Nelson and Co., of Carlisle, having determined to use arc lamps to enable this to be done. We may add that the installation at Cardiff Castle comprises 300 Swan lamps.

Telegraphic Extension in Shetland.—Mr. Laing, M.P. for Orkney and Shetland, has written to Mr. Garriock, of Lerwick, with reference to the proposed telegraph extension to fishing stations on the west coast of Shetland. Together with Mr. Laing, Lord Rosebery, Sir Donald Currie, M.P.; Mr. J. C. Dundas, M.P.; and Mr. John Pender, M.P., will co-operate in urging the Treasury to appropriate from the Herring Brand Fund the guarantee required for the Post Office. Mr. Laing states that the Scotch Fishery Board has been informed by the Treasury that it will adopt any estimate by the Board for thus applying the surplus of the Herring Brand Fund. Mr. Laing further states that the Scotch Fishery Board have now recommended this course, and that the matter may thus be considered settled. Mr. Pender writes approving of the movement, and thinks the Government ought to connect by telegraph every outlying place in the country, not only for fishery purposes, but as a matter of security. He is further of opinion that poorer places should be helped out of the superabundance of richer ones, and that the Government has no right to make the telegraph system simply one of revenue. They ought to look more to public interests and the requirements of trade. When Parliament meets he thinks a deputation from districts interested should wait upon the Postmaster-General to urge this policy.

The Gulcher Electric Light Company.—In our recent review of the electric lighting work of the past year we were unable to include that done by the Gülcher Company, owing to the information not being to hand. We may mention now, however, that this company supplied lamps and machines for erection in the following works, &c., during 1882:—The collieries of the Earl of Durham, the Patent Shaft and Axletree Company's works, Wednesbury; the Oude and Rohilkund Railway Company, for lighting their new bridge across the Ganges at Benares; Messrs. Morewood and Company's Soho Iron Works, Birmingham; Messrs. Joseph Sykes and Company's Cloth Mills, Huddersfield; Messrs. Evans and Owen's premises, Bath; Messrs. Ransomes and Rapier's works, Ipswich; Messrs. Miles Brothers and Company's establishment in New Zealand; to Mr. J. Oppenheimer, of Manchester, for shipment to Australia; Messrs. Schoeller and Sons' establishment at Zurich; and the Telephone-Industrie-Gesellschaft, Zarich. We are further informed that in almost all of these installations both arc and incandescent lamps are being run from the same dynamo machine, an advantage which is peculiar to the Gülcher system. Besides carrying out the above installations the light was exhibited with success at the Horticultural and Botanical Fêtes, at the North East Coast Exhibition, Tynemouth, and at the London Hospital.

Telegraph Clerks' Grievances.—A largely-attended meeting of the Liverpool postal telegraph clerks was held in Liverpool on Saturday evening last, at which delegates from Manchester, Preston, and other towns were present. The following was the first resolution passed:—"That this meeting is deeply dissatisfied with the scheme of revision applied in 1881 to Her Majesty's Telegraph Department, and cannot regard as final any scheme which fails to satisfy claims put forward in the petition of the postal telegraph clerks of the United Kingdom to the Postmaster-General in 1881." It was stated that Mr. Fawcett's scheme retained a system of classification which would prevent all but a few of the junior clerks from ever obtaining a salary higher than 38s. per week, although many of them were now old servants of the department, and that the maximum salary given to first-class clerks amounted to only £130 per annum. The petition referred to proposed to abolish classification and to introduce a scale of salary rising from 16s. per week by 2s. per week each year until £200 per annum was reached. It was explained that this would place the Telegraph Department in no better position than that of other departments of the service, where the work done was of less importance and less onerous, and did not require more intelligence or skill; and it was urged that the moderation of the proposal was shown by the fact that so long a service as that of 31 years would be necessary to reach the maximum salary. The second resolution was as follows:—"That this meeting calls upon the Central Committee of the Postal Telegraph Clerks' Association to use every legitimate means to obtain the concession of the claims put forward by the postal telegraph clerks of the United Kingdom in their petition of 1881." The mover of the resolution said that these claims had been deliberately framed, and would not be abandoned. For some time little had been heard of the movement, but the reason of that was that the leaders wisely determined to refrain from hampering the heads of their department at a time of great political anxiety; but while deferring to the prudence of such a course in the past he viewed with satisfaction the signs of increased activity, for the time had now arrived for a renewal of their demands, and the clerks throughout the country were prepared to act with greater vigour. In every town of importance meetings would shortly be held, and their claims, which all along had had the support of those best qualified to pronounce upon their justice—viz., the Press and the commercial public—would still meet with that support, and by its aid their cause could not fail eventually to succeed. The resolutions were passed unanimously.

Transmission of Power by Electricity.—The correspondents of three daily papers have each sent to their respective journals glowing accounts of some experiments made by M. Marcel Deprez on Tuesday last, to illustrate the transmission of power by means of the electric current. The *Daily News*' representative said:—"Interesting experiments were made to-day (Tuesday) in the workshops of the Northern of France Railway on the system of M. Marcel

Digitized by Google

Deprez, the greatest authority on electricity in Paris, for transporting force over great distances. A dynamo-electric machine transported a force equal to about 3 horse-power a distance of 20 kilometres by means of a single ordinary iron wire, and afterwards 10 horse-power over a distance of 35 kilometres. Hitherto it has not been thought possible to transport a force beyond two kilometres with a minimum loss of 50 per cent., although thick copper wires were used as conductors. The French Syndicate of Electricity, presided over by an American, Dr. Cornelius Herz, and of which MM. Hebrard, Bapts, Reinach, and Dalloz are members, are about to construct a generating Deprez machine of 1,000 horse-power, which is to distribute for practical application 500 horse-power over a distance of 100 miles." The *Daily Telegraph* gives a similar account of the experiments, with this difference. Its representative says:—"Upwards of 3 horse-power was first transmitted a distance of 20 kilometres, and then 35 kilometres, by means of an ordinary wire four millimetres in diameter." It will be observed that the *Daily News* said 10 horse-power was sent over a distance of 35 kilometres. The *Standard* gives the same figures as the *Daily News*. It varies its description, however, by saying that at previous trials "as much as 5 horse-power had been sent through, but yesterday (Tuesday) only 3 horse-power was transmitted." It mentions also that "some incredulity appeared to prevail at first, but in the end it was clearly established that 3 horse-power was transmitted." We would call attention to the fact that none of the accounts mention the actual power that was put into the transmitting machine, with the exception that the loss incurred in transmission is given as about 50 per cent. From private information we may say that we have the best of reasons to believe that of the horse-power put into the transmitting machine, not one-third was given out at the receiving machine. Several Englishmen were present at the experiments, and we do not think they were at all satisfied with the success attained. We admire M. Deprez for his experimental pertinacity, but we do not think that he can be said to have reached anything like the point necessary for the practical carrying out of his system with economy. It would be as well if these experiments were not quite so much noised abroad by that portion of the Press which knows next to nothing about the question, as it is easy to entirely mislead the public without intentionally misstating facts.

Electric Lighting and Plant Growth.—In the Chemical Society's *Journal* for January is an abstract of a paper by M. P. P. Déhérain in the *Annales Agronomiques*, Vol. 7, pp. 551—75. The author's experiments were made at the Palais d'Industrie during the electric exhibition of August, 1881. A green house was constructed and divided into two compartments, one of which was glazed with blackened perfectly opaque glass, whilst the other was exposed to the ordinary diffused daylight of the exhibition building. The darkened chamber was illuminated continuously, night and day, by a 2,000 candle arc light from a Gramme machine, driven by an Otto gas engine. The transparent chamber was illuminated at night only by the electric light. Five series of observations were made, viz.:—1. Plants exposed night and day to the electric light alone. 2. Plants exposed during the day to the diffuse daylight of the Palais, and during the night to the electric light. 3. Plants living during the day in the open air, and receiving the electric illumination at night. 4. Plants passing the day in the diffuse daylight of the Palais, and the night in darkness. 5. Plants living normally in a garden. The plants submitted to experiment were barley, flax, beans, and a number of garden and greenhouse plants. At the end of seven days the naked electric light was seen to have an injurious effect both on those plants which were constantly subjected to it, and in a less degree on those which were exposed to it during the night only. The leaves blackened, withered, and dropped off; the injury was confined to the epidermal layers, and was due to the direct impact of the luminous radiations (and not to the formation of nitrogen oxides); for where one leaf was partly shaded by another, a sharp line was photographically impressed. Experiments on *elodea canadensis*, submerged in flasks of water, showed that whilst the diffuse daylight of the building was unable to cause decomposition of carbonic anhydride and evolution of oxygen, the direct rays of the electric light were able to do so, about as much oxygen being obtained during an exposure of four or five days and nights to the electric light as could be obtained in an hour or so in bright sunlight. At the end of 15 days the arc lights were enclosed in globes of transparent glass, Siemens's just published experiments having shown that the injurious action of the direct radiations was thereby modified. A number of fresh and uninjured plants were placed in the greenhouse, and, in addition, sowings of barley, oats, peas, maize, beans, which had just appeared above the ground. All the seedlings exposed exclusively to the electric light perished sooner or later, and the leaves of some of them were blackened as with the naked light. The mature plants, on the other hand, continued to vegetate, but in no case, save a plant of barley, were flowers and seeds produced, the vegetation being purely foliaceous. The barley grains were normal, and germinated on being sown. The electric light employed was clearly insufficient by itself to determine the assimilation of any considerable quantity of material. Direct experiments also proved that it is not more powerful in exciting transpiration of water, a leaf exposed to it giving off in an hour only about one-fiftieth of the quantity of water evaporated under similar circumstances in sunlight. As the evaporation of water by the leaves is one of the chief agencies in causing the migration of material necessary for the maturation of seed, the failure of the plants to produce flowers and seeds receives its explanation. It is known that yellow and red rays are most powerful in causing transpiration, whilst the electric light is particularly rich in blue and violet rays. The author considers the electric light employed as too feeble to allow of any conclusion as to the necessity of a nocturnal rest to plants. It was, however, evident that the electric illumination during the night was advantageous to those plants which passed the day in the rather feeble diffused daylight of the Palais. In a third series of experiments the intensity of the electric light was practically augmented by placing the plants nearer the lamp. The experiment was again fatal to young seedlings receiving the electric light exclusively, but many of the hardier and more mature plants survived, although the leaves of some were blackened by their two great proximity to the light; and again the nocturnal electric illumination was decidedly favourable to the plants which passed the day in the light of the Palais. The author sums up his conclusions thus:—1. The electric arc light emits radiations which are injurious to vegetation. 2. Most of these radiations are arrested by colourless glass. 3. The electric light emits radiations powerful enough to maintain mature plants in vegetation for two months and a half. 4. The beneficial radiations are not sufficiently powerful to cause the growth of germinating seeds or to allow of the maturation of fruit in older plants.

THEORY OF MICROPHONE AND RESISTANCE OF CARBON CONTACTS.

BY OLIVER HEAVISIDE.

That a joint between two wires required to be firmly made in order to make good continuity for the current was probably learnt by the very earliest experimenters in galvanic electricity. It certainly became matter of common knowledge when telegraphs were practically introduced, and it may have been often noticed that the current passing a contact was decreased when the pressure relaxed before becoming actually interrupted. Now that we know how easily this fact lends itself to the electrical transmission of speech, it seems (after the event) surprising that it was not done generations ago. The nature of acoustical vibrations was known, and with the knowledge of the variation of current with pressure little more was required. We can now make a Morse key transmit speech; very badly, it is true. But the best microphone transmitters are bad enough, so what can one expect from a Morse key?

However, it seems to be established that Reis utilised the phenomenon in his transmitter, long erroneously supposed to work only by makes and breaks. Indeed, presuming that he was at first unacquainted with it, and to be adjusting his transmitter very finely, it would have been difficult for him to have *not* noticed that the current passed continuously with very light contact; and the wonderful change produced thereby, a harsh, disagreeable tone being replaced by a soft and smooth one, would be unmistakable. And, in fact, he did transmit speech in this way with unbroken current. If Reis had but employed carbon contacts instead of metallic, there can be little doubt that the practical introduction of telephony would have been much accelerated.

But, not to enter upon matters historical or controversial, or the labours of subsequent experimenters and inventors, why does the current passing a light contact vary with the pressure? In a sense the theory of the microphone is not affected by the answer, for, only granting the fact, this theory follows immediately:—That we make a light contact in a circuit, vary the pressure between its members by setting it in vibration, vary the current in a somewhat similar manner, vary the attraction on the telephone armature, and set it vibrating. With so many transformations from the speaker to the telephone disc, it would not be fair to expect an exact reproduction of his voice. And we do not get it. It is recognisable, and even intelligible, if one has good ears. It is said that some of the Middle Age artists used to write "This is a horse," &c., by the side of their representations, to prevent any misconception. Something of the same kind is really wanted with some microphone transmitters in extensive use. A stranger requires to be told what the funny noise is meant for, and then he may understand it. Some never do.

In a certain transmitter, which is, relatively speaking, a good one, one contact piece is fixed to the centre of a thin board, the sound board in fact, and the other is mounted upon a spring and presses gently against the first. This is only the Morse key arranged for continuous light contact, arranged to be worked by the air vibrations instead of by hand. The sound board is spoken to, it moves to and fro and varies the pressure, and there is, or should be, no jolting, or scraping, or interruption of the current.

Professor Blyth's arc microphone seems to be a thing *sui generis*. There is no visible contact; a strong current is employed to maintain an arc, and it can be made to transmit speech. Granting that, according to Professor Blyth, the action is really direct action of the air vibrations on the arc (though how the electrodes are to be stopped vibrating by making the fixtures heavy is not very evident), it yet seems an extraordinary step to take to conclude that the same thing happens in contact microphones, that the tremor breaks contact, sets up arcs, which are then acted upon directly by the air vibrations. The fact that a strong current is required in the arc arrangement, and a circuit of low resistance, alone seems sufficient to invalidate the conclusion. But when we consider that in a contact microphone the slightest discontinuity, the least amount of sparking, at once spoils the microphonic action, the whole ground of the explanation seems undermined.

Granting, now, that there is no arc in the ordinary sense, as there could not be with such relatively considerable pressures as can be employed between the contact pieces without so much enfeebling the action that no sound is given out by the telephone, there is yet much to be learnt concerning the nature of the apparent assistance which is presented by a contact. I made some time ago numerous experiments on this subject, which led me to the conclusion that it was principally the air that was concerned, and I am confirmed in this belief by Mr. Berliner's interesting communication (*Electrician*, p. 135 *ante*), in which he states a good case against the arc theory, and that a Blake transmitter in vacuo had only 2-10ths of an ohm resistance, which was that of the air left.

There is, or seems to be, a cushion of badly-conducting air between two pieces of carbon in contact, which air is partially squeezed out by increasing the pressure, and the resistance is simultaneously reduced, more points or a larger surface of carbon being brought into real contact, if there be such a thing. At any rate, this is in harmony with the difficulty of ensuring a really good connection between wires, considerable pressure being required. In soldering, also, the solder displaces the air, and, besides enlarging the area of contact, of course stops the oxidation that the displaced air would cause.

But there is uncertainty here. We do not know whether the conduction takes place between those parts of the carbon pieces which we may assume to be in real contact—conduction of the metallic nature; or whether there is conduction through the air elsewhere; or whether there is any real contact at all (except under considerable pressure) so that the conduction is invariably through a layer of air, apparently continuously and without disruption, though if the discharges were only sufficiently rapid, we should know nothing of them.

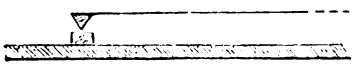
If we have two carbon pieces with flat surfaces, place them in contact equally parallel, and have them mounted so as to be capable of to-and-fro motion; and if we assume that with increased pressure more points are brought into contact, which is reasonable enough, and, further, that the conduction is of the metallic nature, we can deduce these results. The contact resistance should vary inversely as the area with the same pressure, and be independent of the current strength. Two similar contacts, separately adjusted to exactly the same resistance, should present double the resistance when put in sequence, and half the resistance when abreast; and similarly for other combinations. We should be able to arrange contacts like battery cells, in tandem, and abreast, so that when all were similarly acted upon with the same vibrations we should obtain the greatest variation of current in the circuit. The best arrangement for a definite variation of pressure would be that in which the resistance of the external circuit, supposed constant, and containing a constant E.M.F., equalled the geometrical mean of the highest and lowest resistance of the combination of contacts under the given change of pressure, which we may consider as approximately equal to the resistance when in quiescence.

But all this is wrong. The resistance is not independent of the current for the same pressure, but varies considerably when the pressure is light, so that all conclusions based upon Ohm's law, $E = RC$, with R independent of C and E, are erroneous. The contact conduction can therefore be only partly of the metallic nature, mostly so when the pressure is not very light, for there is then the least departure from $R = \text{constant}$; and the air therefore probably plays an important part in conducting the current, besides serving to prevent metallic contact, and a part of the apparent resistance is of the nature of a back E.M.F.

To make exact observations, contacts, though light, should not be loose. They must be definite, capable of easy regulation, and of exact reproduction as regards a given state. For this, there seems nothing better than to fix one piece rigidly to the sound board, and the other piece on the end of a light flat spring, whose further end is securely fixed to some place where there is compartively little amplitude of vibration. If the spring be horizontal, the most feeble pressure

Digitized by Google

may be obtained by first adjusting to nearly give contact, and then placing a small weight on the spring; and, by altering its position, the pressure may be varied by very small amounts. The connections should be so arranged that



there is no straining of the spring by wires, or of the board either, as great differences in the current passing may arise from shifting wires.

The elementary contact is that between a point and a *plane*, not between two points. The point, to localise the discharge; the plane, because it does not require any adjustment to meet the point, which should only have motion perpendicularly to the plane. So one piece of dense carbon may be ground to a cube, or, at any rate, with two flat parallel surfaces; the other to a point, with a flat side opposed. All dust should be removed, as it introduces irregularities.

Join up with a battery, a telephone, and a galvanometer (say a tangent, to measure current-strength). The galvanometer is indispensable, for the telephone gives us little information as to current strength; and the telephone should be used constantly, as it tells us a great deal about the state of the contact that the galvanometer cannot. No bridge, and no induction coil. The bridge is of no use for such variable resistances as are presented by very light contacts, and especially so when the resistance varies with the current strength. To measure roughly the resistance r of a contact, observe the current before it is introduced into the circuit and after, say, C and c; then $r = \frac{E}{C} - \frac{E}{c} = \frac{E}{G}(\cot\theta_2 - \cot\theta_1)$, where G is the galvanometer constant, E the E.M.F. of the battery, θ_1 and θ_2 the deflections. Thus, r is proportional to the difference of the cotangents. To obtain suitable falls of deflection, vary the resistance of the circuit or vary E.

If we have, say, a dozen contacts, as above, and observe their resistance and microphonic action under different pressures, no two of them will behave exactly alike. There is, however, in the majority of cases, a general resemblance, and the following I found to be typical. If the point be heavily weighted, there is no appreciable resistance; with very light pressure there is a considerable fall in the current. If the contact be then let alone, the current will remain nearly steady for long periods, with only slow variations of not great amount. Using one cell Leclanché in a circuit of 72 ohms resistance without the contact, with deflection 54deg., when the deflection fell to 50deg. by reducing the pressure, indicating a contact resistance of 11·2 ohms, the sound of a watch placed upon the sound-board as a constant source of sound was just audible in the telephone. The sound increased, though not very rapidly, until 35deg. was reached, indicating a contact resistance of 70 ohms. From 35deg. down to 20deg., when the resistance was 202 ohms, the sound increased much faster, and was now about three times as loud as that of the watch itself when placed close to the ear instead of the telephone. Below 20deg. the microphonic action became imperfect, due to slight breaks mixed up with the proper continuous action; and at 15deg. (resistance 300 ohms) the contact broke suddenly, and could not be permanently maintained at that pressure. If the deflection were above 20deg. it could be maintained nearly constant for a long time, with perfect microphonic action without sparking. (Watch with face upwards, for when placed the other way, glass upon board, there was a violent kick at every second tick, which broke contact.)

The point at which the watch became audible was naturally very variable, as it depended so much on quietude. Again, the point at which the break occurred was variable with different contacts, as any slight noise was sufficient to cause the break. But below a certain point, the current once broken would not remake itself. It required the assistance of a touch, or another noise. This was independent of any permanent change of pressure.

Some contacts, however, though seemingly just the same as the rest, would not behave regularly. The sound was as usual in the earlier stages, though not so good as it should have been; but when the later stages were reached, say at 30deg., there was a stoppage of the regular sequence. Poor action. Left to itself, the contact changed so that the current through it, instead of remaining steady, decreased rapidly, the deflection sometimes going down to zero (or less than ½deg. at any rate); and whereas the normal contacts were at their best, microphonically, nearly up to their breaking point, these abnormal contacts got worse and worse, the sound becoming feebler and feebler, though even with no visible current passing the watch was still faintly audible. This "bad" behaviour also varied capriciously, the current undergoing changes somewhat like earth-currents (except as regards reversal of direction), *i.e.*, gradual, but great. I was never able to settle decisively the cause of this; sometimes carbon dust produced a similar effect; sometimes repointing the point or replaning the plane removed the evil, but frequently it did not. So, although bad contact in one sense is essential to microphonic action, yet there must be good contact in another sense. All such bad contacts were rejected in making comparisons later, only the normal ones being used. Sometimes a contact which had been good for many days got wrong, in some unknown manner, and behaved in the bad fashion, and stuck to it too.

Of course a contact when adjusted so finely as described would not do for speaking purposes, as it would break at every syllable; but it answers for distant and faint sounds, whether speaking or not, a German band down the street, for example, or distant church bells. There must be no sparking whatever if the continuous microphonic action is to be preserved. Sparking is generally easily distinguishable by the peculiar sound it causes, and when the telephone indicates its existence it may be detected by ocular inspection, unless it be very minute. The microphonic action is loudest and best (for feeble sounds) when the current is least (excepting in the case of the "bad" contacts). The deflection is the same whether the sound-board be vibrating or not, except that there is a slight fall for loud sounds, even when they do not break the contact, thus showing that the average current is somewhat reduced. At the same time it is noticeable that the watch-sound gets louder when there is another sound going on, without any particular fall in the current. What the extent of variation of current is, the galvanometer will not say. It may be roughly guessed from the intensity of sound produced by breaking the circuit, and this only tells us that the variations are very small when speaking to a transmitter with coarse adjustment, and very great, perhaps as much as 30 to 50 per cent., when the adjustment is very fine, and the sound-board motion is nearly sufficient to break the contact. The disc of the telephone (a flexible disc) could also be felt to be strongly vibrating when a finely adjusted transmitter was spoken to, care being taken not to break contact.

Now regarding other forms of contact. If we round the point slightly like a worn lead-pencil point, we get substantially the same results, both as regards resistance and the corresponding intensity of sound; but it is not so perfect in the finer stages, and it is the same with any kind of contact substituted for the point, if the current passes always at one place. On the whole, though, they are more irregular than points, and the more so the flatter they are.

Flat contacts are peculiar. If the two surfaces be not exactly parallel, they will only touch at a corner, or along a portion of an edge of one of them, and the behaviour is not much different from that of a point and plane; but if care be taken to grind them quite flat, and to mount them so that, on slightly separating them, sparking can be seen to go on quite irregularly at various places, so that we may be sure that the surfaces are practically parallel, then, when brought into contact by slightly weighting the upper one, we know that there is contact at many places, and we find that it behaves perfectly abominably. The regularity of action is quite gone as regards the state of fine adjustment, and it is vastly inferior to a point microphonically. The resistance, instead of being less, is, with light pressure, usually much higher and the current varies, as with a "bad" point. Therefore flat contacts were rejected.

With respect to the resistance of a contact, it varies accor-

Digitized by Google

ding to the current passing. But there are two principal ways of considering the resistance. We may calculate it as resistance by Ohm's formula, and we then find that it decreases greatly as the current rises, with the same pressure; the current being made to vary by inserting or removing resistance from the circuit, or by varying the number of cells in the battery. Or we may reckon it as a back E.M.F. without resistance, say e, so that if E is the battery E.M.F., $(E - e)$ is the actual E.M.F. in the circuit, on the assumption that the real resistance is that of the rest of the circuit. We now find that e rises with the current, though not nearly so fast as the resistance falls on the former assumption. There is probably both a back E.M.F. and resistance at a light contact, but it is not easy to separate them, owing to the variations going on. As far as mere calculations go, it is simpler to employ e, especially with combinations of contacts.

The resistance r on the assumption of no back E.M.F., and the back E.M.F. e on the assumption of no resistance, are thus connected. Let E and R be the E.M.F. of battery and resistance of circuit without contact, and let the current fall from C to c on inserting the contact. Then,

$$c = \frac{E - e}{R} = \frac{E}{R + r} = \frac{e}{r}.$$

In the example before mentioned of a typical point and plane contact we have

$c =$	20·6 ...	17·8 ...	10·5 ...	5·5 ...	4 milliams.
$e =$	0 ...	·2 ...	·75 ...	1·09 ...	1·2 volt.
$r =$	0 ...	11·2 ...	70 ...	202 ...	300 ohms.

This is with E and R constant, and pressure varying.

Now, keeping the contact at constant pressure, and varying the current, if the pressure be not too light, the deflection keeps steady (*i.e.*, with a particular E and R), but when very light, care is required that the contact does not vary much during a series of observations; so that it should be repeated backwards and forwards two or three times to see if consistent results are obtained, all anomalous series rejected, and only those chosen which give nearly the same result on returning to the same E and R. A good series was the following:—

Contact out	20½° ...	35° ...	45° ...	52° ...	56°
„ in	13° ...	25° ...	36° ...	44° ...	50°

These give

$c =$	3·4 ...	7 ...	10·9 ...	14·4 ...	17·8 milliams.
$e =$	·57 ...	·93 ...	1·09 ...	1·25 ...	1·16 volt.
$r =$	166 ..	133 ...	100 ...	87 ...	65 ohms.

c is, of course, the current corresponding to the lower deflection. Very roughly, the apparent resistance varies inversely as the square root of the current. No particular importance can be attached to the figures as regards exactness, for it was a very light contact (and therefore somewhat variable), in order to get a good fall of deflection, which is necessary, because 1deg. makes a considerable difference when the fall is small.

The work done by the current at the contact is ec, or rc^2, or $e_1c + r_1c^2$, if e_1 and r_1 are the real back E.M.F. and resistance at the contact. In the above case we find

$$ec = \cdot0019 \ldots \cdot0065 \ldots \cdot0118 \ldots \cdot0180 \ldots \cdot0206$$

The loudness of the sound given out by the telephone is not proportional to the work done at the contact; for if so it would be a maximum when $e = \frac{1}{2}E$, which is not true. In the case previously mentioned (varying pressure), $e = \cdot8$ E gave the loudest sound, just before breaking, and there is never any falling off except with "bad" contacts. With "good" contacts the sound is always greatest with the least current, provided it be continuous (the battery being of course kept the same), and its intensity is roughly proportional to e, except when e is above $\frac{1}{2}E$, for in the later stages the sound increases much faster than e.

Thus, if we adjust two similar contacts carefully to the same resistance (both planes on middle of board and points on separate springs), and then put them in series, the sound is nearly doubled if e is, say, below ·2 E for each contact, and we find that the back E.M.F. of the two is a little less than the sum of the separate E.M.F.'s, and the resistance of the two not much greater than the sum of their separate resistances. But if e for each contact is greater, say ·5 E, the sum of the E.M.F.'s shows a large falling off, and the sum of the resistances a large increase, and the sound is much less than double that of either.

If we have six similar contacts, each by itself giving the same resistance and sound, putting them in series increases the sound up to, say, three contacts, after which there is little perceptible increase. The current falls a certain extent on adding a fresh contact, but comparatively much more for the later additions than for the earlier. This may be understood by remembering that every contact added reduces the current, and that the resistance of all of the contacts increases simultaneously, and the more so as the current gets smaller. The more sensitive the contacts are, the less advantage there is in putting them in series.

When two contacts are unequally strong, and e is small, they add their effects, both as regards e and the sound. Thus $e_1 = \cdot17$ E, $e_2 = \cdot22$ E; $e_1 + e_2 = \cdot36$ E. Even if e is great for one and small for the other, there is usually a slight increase, or, at any rate, no decrease. If both are made as sensitive as possible, and as equal as possible, putting them in sequence usually increases the sound very little, but this varies according to the resistance of the circuit, on which depends the amount of fall of current on inserting the second contact (the first being already in).

Thus $e_1 = e_2 = \cdot6$ E; $e_1 + e_2 = \cdot81$ E.
$e_1 = \cdot61$ E; $e_2 = \cdot16$ E; $e_1 + e_2 = \cdot67$ E.
$e_1 = \cdot33$ E; $e_2 = \cdot38$ E; $e_1 + e_2 = \cdot59$ E.

On the whole, I found that the calculated value of e was a sort of guide, though not by any means a perfect one, to the intensity of the microphonic action. Sensitive contacts in series require separate examination in turns (by short-circuiting all except one) occasionally, to see that they keep steady. To go by the apparent resistance is very misleading.

But there is also the battery E.M.F. to be considered. The loudness appeared to be about proportional to the number of cells used, from 1 up to 5, with circuit resistance 150 ohms; so that the product Ee would be roughly proportional to the intensity of the sound, or otherwise proportional to the product of the current without the contacts into the fall of current on inserting them. This is true in a large number of cases, but must not be carried to extremes. Thus if one contact brought deflection from 42deg. down to 10deg. with one cell, putting it in sequence with a similar one brought deflection down to 5deg. or less, but with no increase of loudness, in fact a slight decrease; whereas in making the same experiment with 5 cells there was a slight increase. It was also verified many times that if two contacts adjusted equal in the first place, and then put in sequence, bring deflection down to 10deg. (with 1 cell), there is less sound than with either of them alone when adjusted so as to cause the same fall of current. Also, with many contacts in sequence, the sound ultimately decreases, the later additions having apparently much higher resistances than the earlier; the sound increases by addition of two or three, is then about constant with one or two more (all separately giving good sound), and finally decreases on further additions being made. Now here e, calculated for the whole as for a single contact, continually increases, although it becomes practically constant, because the reduction of current for, say, the 6th contact, although it may be considerable compared with the current already reduced by the first five, is quite small compared with the original current.

Contacts in parallel are behave, in the main, as might be expected from the relation between e and the current passing observed in the case of a single contact. The total current is always increased by putting two contacts abreast; *i.e.*, it is greater than through either of them when the other was disconnected, and this is true whether the contacts are separately equal or not. As for the sound, it is never increased, and is generally reduced. If the contacts be unequal, the joint sound is intermediate between their separate sounds. When one is very weak, it shuts up

Digitized by Google

the other, however good it may be, which is sufficiently plain, because nearly all the current goes through the weak one. Should there be a difference in character in the sound of the contacts taken separately, such difference will be also recognisable to a certain extent when they are put abreast. Otherwise there is simply a weakening of intensity, unless both are in a very sensitive condition, in which case there is little perceptible difference acoustically between A and B singly and A and B in parallel arc. Now in this last case the current through each is halved when they are put abreast, which involves a reduction in e (or larger increase in r), and at the same time the total current is increased.

Owing to the unknown real resistance, it is desirable to make contacts exactly equal first, before putting them abreast, so that we know that the current goes half through each, whatever their resistance may be. If they could be regarded as battery cells of constant resistance and E.M.F., observations of the fall of current in sequence and abreast and cut out would allow us to reckon the real resistance. But there is no harmony in the results. Four deflections, taken in all possible pairs, gave for the resistance of a single contact from 32, through 42, 46, 55, 61, up to 76 arbitrary units.

On the other hand, calculating e from the results and comparing with the corresponding current, and making allowance for the halving of current when abreast, a fall of e with reduced current was obtained, similar to that observed with a single contact on varying the external resistance.

In concluding this abstract, I will merely add that a great deal of patience is necessary when working with very light contacts, and that when combinations are made, something more than patience is required, and many precautions must be taken, to be found by experience, else very contradictory results may be arrived at.

ON THE ELECTRICAL RESISTANCE OF CARBON CONTACTS.*

BY SHELFORD BIDWELL, M.A., LL.B.

The experiments described in the paper were undertaken with the object of investigating the changes of resistance occurring in carbon cantacts under various conditions.

A short movable carbon rod was placed across, and at right angles to, a similar rod, which was fixed in a horizontal position, and arrangements were made for varying and accurately measuring the pressure of the one upon the other; for varying and measuring the current passing through them; and for measuring the resistance at the points of contact. The following are the most important results arrived at:—

1. *Carbon Contacts.*—Changes of pressure produce proportionately greater changes of resistance with small pressures than with great pressures. Thus, when the pressure was increased from ·25 to ·5 grammes, the resistance fell from 16·1 to 11·8 ohms, the difference being 5·1 ohms; whereas, when the pressure was increased from 25 to 50 grammes, the resistance fell from 2·1 to 1·8 ohm, the difference being only ·3 ohm.

Changes of pressure produce proportionately greater changes of resistance with weak currents than with strong currents. Thus when the pressure was increased from ·25 to ·5 gramme, the resistance fell from 9·27 to 8·45 ohms with a current of ·1 ampere, and from 25·50 to 17·75 ohms with a current of ·001 ampere.

Changes of current produce proportionately greater changes of resistance with small currents than with large currents, and with light pressures than with heavy pressures.

When the resistance of a carbon contact has been reduced by an increase of pressure, it will, on the removal of the added pressure, rise to approximately its original value.

The passage of a current, the strength of which does not exceed a certain limit, depending upon the pressure, causes a permanent diminution in the resistance (so long, of course, as the contacts are undisturbed), and, the stronger the current, the greater will be such diminution.

When the strength of the current exceeds a certain limit the resistance is greatly and permanently increased (generally becoming infinite). The greater the pressure the higher will be such limit.

Unless special means are adopted for maintaining a constant current the fall in the resistance which attends increased pressure is greater than that which is due to increased pressure alone, being partly due also to increased current.

It is not proved that the diminished resistance which follows an increase of current is an effect of temperature.

2. *Metallic Contacts.*—For the sake of comparison a few experiments were made with metals. The metal principally used was bismuth, which was selected on account of its high specific resistance, but experiments were also made with copper and platinum.

In the case of bismuth, and probably of other metals, with a given pressure the weaker the current the higher will be the resistance. This effect is most marked when the current is small. Thus, with a pressure of ·1 grm. the resistance with a current of ·1 ampere was 2 ohms, with ·01 ampere it was 16·92 ohms, and with a current of ·001 ampere it was 143·3 ohms. With a pressure of ·5 grms the resistance with the same currents as before was 1·45, 1·47 and 3·8 ohms.

The passage of a current, even when very small, causes a permanent adhesion between metallic contacts. This effect had been previously observed by Mr. Stroh.

Increase in the current is accompanied by a fall of resistance, and if the current be again reduced to its original strength, the resulting change in the resistance will be small, and it will in no case return to its original value.

Diminution in the strength of the current is followed by a small fall in the resistance if the metal is clean, and by a small rise in the resistance if the metal is not clean.

Increased pressure produces a greater fall in the resistance with small pressures than with great pressures, and with weak currents than with strong currents.

The resistance, after having been reduced by increased pressure, does not return to its original value when the added pressure is removed.

Reasons for the superiority of carbon over metal in the microphone.—The above observations may, perhaps, furnish an answer to the question, why does carbon give far better results than any metal when used in the microphone? The mere fact that a current causes delicately-adjusted metal contacts to adhere to each other seems sufficient to account for the superior efficiency of carbon. In addition to this phenomenon of adhesion, and probably connected with it, are the facts that metallic contacts, unlike those of carbon, do not even approximately recover their original resistance when once it has been reduced by increased pressure or increased current, unless, indeed, complete reparation occurs; and even the initial effect of pressure upon resistance is in general much more marked with carbon than with metals.

Lastly, there is the fact that in the case of carbon pressure and current act in consonance with each other; pressure diminishes the resistance, and in so doing increases the strength of the current, and the current thus strengthened effects a further diminution in the resistance. In the case of metals, on the other hand (or at least in the case of clean bismuth), pressure and current tend to produce opposite effects. The resistance is diminished by pressure, and the current consequently strengthened; but by reason of the increased strength of current the resistance is *higher* than it would have been if the current had remained unchanged. The effect of this antagonism is not very great, but it seems sufficient to give a material advantage to carbon.*

The paper contained fifteen tables, four curves, and three diagrams, illustrative of the apparatus used.

* Abstract of a Paper read at the Royal Society, Feb. 1, 1883.

[* In April, 1882, the author communicated this observation to Mr. Preece, who referred to it in a paper read at the Southampton meeting of of the British Association on "Recent Progress in Telephony."]

PRELIMINARY NOTE ON A THEORY OF MAGNETISM BASED UPON NEW EXPERIMENTAL RESEARCHES.

BY PROFESSOR D. E. HUGHES, F.R.S.*

In the year 1879† I communicated to the Royal Society a paper "On an Induction Currents Balance and Experimental Researches made Therewith." I continued my researches into the molecular construction of metallic bodies, and communicated the results then obtained in three separate papers‡ bearing upon molecular magnetism.

To investigate the molecular construction of magnets required again special forms of apparatus, and I have since been engaged upon these, and the researches which they have enabled me to follow.

From numerous researches I have gradually formed a theory of magnetism entirely based upon experimental results, and these have led me to the following conclusions:—

1. That each molecule of a piece of iron, steel, or other magnetic metal is a separate and independent magnet, having its two poles and distribution of magnetic polarity exactly the same as its total evident magnetism when noticed upon a steel bar-magnet.

2. That each molecule, or its polarity, can be rotated in either direction upon its axis by torsion, stress, or by physical forces such as magnetism and electricity.

3. That the inherent polarity or magnetism of each molecule is a constant quantity like gravity; that it can be neither augmented nor destroyed.

4. That when we have external neutrality, or no apparent magnetism, the molecules, or their polarities, arrange themselves so as to satisfy their mutual attraction by the shortest path, and thus form a complete closed circuit of attraction.

5. That when magnetism becomes evident, the molecules or their polarities have all rotated symmetrically in a given direction, producing a north pole if rotated in this direction as regards the piece of steel, or a south pole if rotated in the opposite direction. Also, that in evident magnetism, we have still a symmetrical arrangement, but one whose circles of attraction are not completed except through an external armature jointing both poles.

The experimental evidences of the above theory are extremely numerous, and appear so conclusive, that I have ventured upon formulating the results in the above theory.

I hope in a few weeks to bring before the Royal Society the experimental evidence which has led me to the conclusions I have named; conclusions which have not been arrived at hastily, but from a long series of research upon the molecular construction of magnetism now extending over several years.

THE B.A. UNIT OF RESISTANCE.

BY LORD RAYLEIGH, F.R.S., AND MRS. H. SIDGWICK.§

The experiments described in the present paper were carried out during the spring and summer months of last year at the Cavendish Laboratory, and are divided into three distinct series. In the first and second series the induction coils were situated nearly in the plane of the revolving disc, as in Lorentz's original use of the method, the difference between the two series relating only to the speed of rotation, which was varied in the proportion of 10 : 16. The third series presents a point of novelty in that the induction coils were separated from the disc to such a distance as to render the accuracy of the result practically independent of the mean radius of the coils.

The small resistance, traversed by the battery current, to which the terminals of the galvanometer branch are connected, was obtained indirectly by a method of shunting. Thus in the first series, the principal part of the battery current passed on one side through two unit coils, placed in multiple arc, and equivalent to $\frac{1}{2}$, and only a comparatively small remainder through a second branch, composed of two coils in series, of values 10 and $\frac{1}{10}$. The terminals of the galvanometer branch were connected with the extremities of the $\frac{1}{10}$, and the difference of potentials between them, due to the primary current, was thus reduced to that which would be required to drive the current through a resistance of $\frac{1}{200}$.

From the first series—

$$1 \text{ B.A. unit} = \cdot98674 \times 10^9 \text{ C.-G.-S.}$$

From the second series—

$$1 \text{ B.A. unit} = \cdot98669 \times 10^9 \text{ C.-G.-S.}$$

From the third series—

$$1 \text{ B.A. unit} = \cdot98683 \times 10^9 \text{ C.-G.-S.}$$

As a mean we take—

$$1 \text{ B.A. unit} = \cdot98677 \times 10^9 \text{ C.-G.-S.}$$

With use of the ratio between the mercury unit and the B.A. unit, found by us (*Proc. Roy. Soc.* May, 1882) this gives—

$$1 \text{ mercury unit} = \cdot94150 \times 10^9 \text{ C.-G.-S.}$$

or, which is the same thing, the ohm is the resistance of a column of mercury at 0° Cent., whose section is one square millimetre, and whose length is—

1062·14 millimetres.

The very close accordance between the result of the present investigation and that obtained by the method of the revolving coil (·98651), and by Glazebrook (·98665), using another method again, leads us to hope that no error of importance can have escaped detection.

The appendix is devoted to a record of experiments having for object the determination of the absolute pitch of a certain tuning fork, which has served as the standard of time throughout all our work upon this subject. It is believed that the method employed is worthy of attention, and may be useful to other physicists.

CORRESPONDENCE.

STATIC ELECTRICITY AND QUANTITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Opinions differ, and will continue to differ, so also will the aspects of natural truths, and the modes of expressing them. Mr. Von Tunzelmann (p. 278) criticises my views from his own point, and I am obliged to him or any one who will, by so doing, enable me to examine all points, because I am conscious how much there is to learn. But I do not care to discuss a single incidental portion of a complete idea, and especially I decline to discuss it on the mystical, artificial principles which I protest against. Whether Mr. Von Tunzelmann cares to examine my complete work or not is a matter for himself; the fact that readers have taken up an edition of 2,000, with scarcely any advertising, justifies me in believing that in my mode of dealing with electrical matters I have met a want. As to the particular subject, opinions differ very much. I received a letter from America, from a gentleman unknown to me, beginning "Permit me to thank you for the instruction your article 'The Inductive and Conductive Circuits,' contained in *The Electrician* for December 23, ultimo, has afforded me. It is just the style suited to the wants of those experimenters who deem life too short to unravel the mysteries of many so-called standard works of the present day."

I expected Mr. Von Tunzelmann to explain to me that current is not a velocity; in fact, I used the particular expression intentionally. In common sense, current is the velocity, or rate of unit transmission. We may express that in a variety of ways, and among others in the form used in the system of "dimensions," which he prefers.

I must correct Mr. Von Tunzelmann as to "Mr. Sprague's

---

Digitized by Google

complacent opinion that Clerk Maxwell was gradually adopting his views." I said nothing of the kind. I said he was gradually adopting views "the same as those I endeavour to sustain." Those views are in the air—held by a large school of electricians, and gradually influencing the whole body. All I can claim in the matter is that I have set them forth in a book, of which one of my reviewers said, "He has boldly accepted the doctrine germinated by Faraday, and *slowly creeping into scientific belief*, that electricity and magnetism are due to the polarity of molecules, and that we are to search for it, not so much in the conductors that bring it within the cognisance of our senses as in the insulating media that are inseparable from its manifestations."

As to the change in Clerk Maxwell's views, it is very evident in his posthumous work, and the general change which is occurring is manifested in every recent book, where we always find two inconsistent explanations given of the phenomena. One thing is clear, Clerk Maxwell says nothing of electric repulsion, but gives what amounts to the same explanation as my own. Further, I quote his own statement:—"I made use of methods I do not think best in themselves, but without which the student cannot follow the investigations of the founders of the mathematical theory of electricity. I have since become more convinced of the superiority of methods akin to those of Faraday, and have, therefore, adopted them from the first." That is just my own position. I say that the purely artificial electricity invented by mathematicians involves an artificial treatment, and that the object of my study is electricity such as it operates in nature, not on the black board of a lecturer's class room.

As to others, we find writers defining unit quantity as that which repels a similar quantity at unit distance with unit force, which is not true, unless we add, under fixed conditions of surroundings and in a specified dielectric, the air. They give elaborate explanations about distribution upon a single surface, all of which are untrue, and which they have to qualify by the statement, "provided they are at a great distance from surrounding surfaces." They talk constantly about putting a charge of electricity upon an isolated sphere, and about the capacities of spheres varying as their radii. In fact, through all their explanations they treat electricity as if it were a single matter, capable of being put upon a single surface. Then they turn round and explain that all these phenomena are entirely dependent on the actions in the dielectric, and that electricity is a dual action setting up stresses in this dielectric. Now, this latter is the truth they are really gradually taking up, while they cling to the older explanations and formulæ inconsistent with it.—Yours, &c.,

J. T. SPRAGUE.

PROPERTIES OF TEMPERED STEEL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to Professor Hughes's interesting paper on the properties of tempered steel, I would venture to ask him if he has tried what results are obtained when steel, which has been perhaps previously dead hard, is heated so as to be just luminous when held in a dark corner, and then quenched. Treated thus, it will be found to be quite soft. Now, to make it dead hard, it must have been at a much higher heat than this just luminous state—bright, cherry red, in fact—and this lower heat would be insufficient to alter the "alloy" formed at the higher temperature, as I read Professor Hughes's paper. I do not think this mode of softening is generally known. Almost daily it will be found useful. The largest piece I have tried, and quite successfully, was 2¼in. diameter by 1in. thick.—Yours, &c.

February 5th, 1883. W. T. F.

THE ACTION OF MICROPHONES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should like to ask Mr. Smillie if he still thinks that the continuity of the contacts does not vary when spoken to, as he said in his first letter? If so, he can (providing his idea be correct) make his Blake speak by closing the circuit through S, C, and B, instead of carrying it through P and R. His instrument will not be altered by this means, so he will be able to adjust it to any degree of pressure he may choose. He says he understood me before, but I cannot think that he did. Perhaps he will be good enough to tell us what *he* means when he speaks of a closed contact. Would he consider it to be properly closed until the fullest amount of current was obtained? The statement in the first letter shows that he considers the contacts to have nothing to do with the matter. I think if Mr. Smillie will pay strict attention to my plan he will be able to prove the thing right or wrong. If he finds himself wrong he will only be in the same position that better men than himself have been in; if he is right, it will be for his opponents to give way. If in writing Mr. Smillie would think a little more of the subject, and a little less of useless expressions, the reader would be the gainer by the change.—Yours, &c., J. RATHBONE.

5, Prospect-place, Treorchy, South Wales.

SELF-REGULATING DYNAMO MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

(TRANSLATION.)

SIR: In your article on "Self-regulating Dynamo Machines" (*The Electrician*, Jan. 20) you very rightly remark that if A B invents something, but keeps that something secret, some one else, C D, may also invent the same thing; but if A B has taken out a patent, then C D's patent is invalid, and the latter has lost his money, and what is perhaps worse, the time occupied in studies, which can be credited to A B alone. It is for this reason that I beg you to be good enough to insert my letter in the next number of *The Electrician*.

If we employ two wires for the electro-magnets of a dynamo, the one as a shunt and the other for the main current, we can then connect up in three different ways, as I have shown in Fig. 1, or, as in Fig. 2, in an intermediate way.

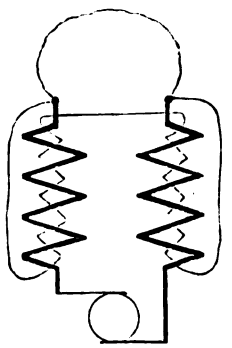

FIG. 1.

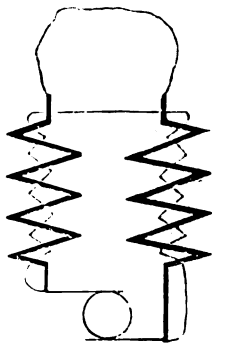

FIG. 2.

Now, I have shown in my patent that in order to obtain the required regularity in the case of a variable number of machines in multiple arc, it is necessary to employ the arrangement shown in Fig. 1; and, in order to have a constant current, we must employ the arrangement shown in Fig. 2, whilst the intermediate arrangement may be used in special cases, such as for running a machine above its normal working power, or for sending a current to a great distance from the machine. You will find this in an extract from my German patent, which I send you herewith privately, and not for publication. You are aware that no one is permitted to make public an invention which he wishes to patent in Germany before it has been published by the Patent Office. I cannot, therefore, say more at present, but I reserve myself the right of publishing later on the methods employed in the construction of my machines, as well as several other means for regulating the current, such as are described in my patent, together with the results of experiments made.

I would only remark that if differences of 6 per cent. have been obtained with the *soi-disant* "self-regulating" machines, as described in an article which has appeared in your paper, it is because the arrangement shown in Fig. 2 has been

Digitized by Google

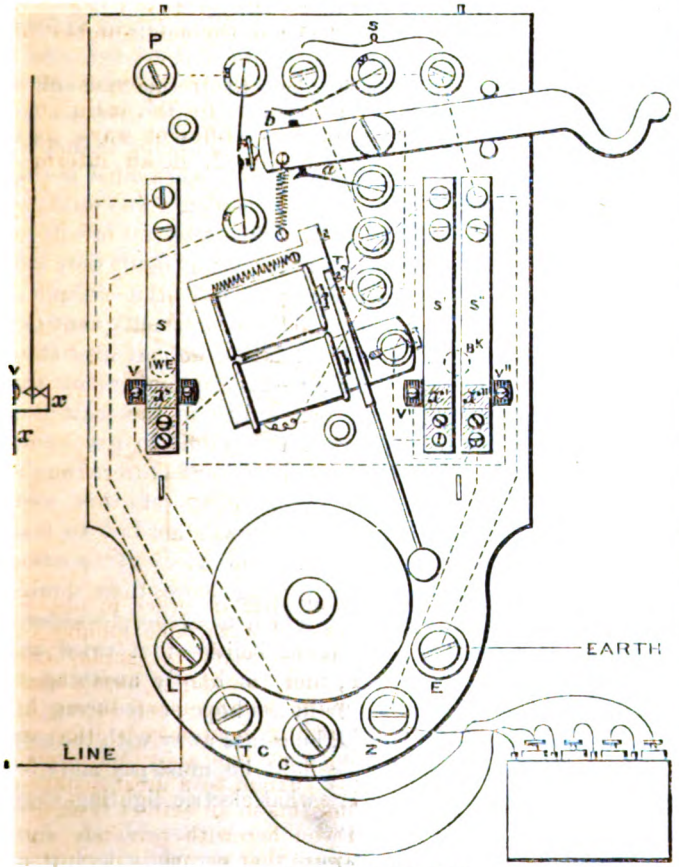
employed, whereas the arrangement shown in Fig. 1 should have been used. These two arrangements, which appear at first sight to be similar, are really very different, and I believe I am the first who has shown in a definite way which should be employed in any case.

If I am a little late with this letter it is not because my invention is of recent date, since I had already applied for a patent in Germany, and other countries also, before the first article on this subject had appeared in *The Electrician*. I did not think that there was any necessity for provisional publication of the matter, but you have convinced me that it is useful "to take some members of the technical press into confidence, and put out of question once and for all claims to priority, by a suitably worded paragraph which records but does not enter into details." *Vide The Electrician*. January 6.—Yours, &c., C. L. R. E. MENGES.

NEW TELEPHONE SWITCH BELL.

DESIGNED BY MAGNUS VOLK.

This bell offers the advantage that a call or answer signal can be given whether the sender's telephone is on the hook or not. It is also fitted with two ringing buttons, black and white. When the subscribers are through, a polarised annunciator in the exchange is connected in a derived circuit from the subscribers' lines, so that they can leave their instruments, and call each other up as often as they please by using the white button; when they have finished the black button is pressed, thus causing the annunciator to drop, giving the "cut-off" signal.



New Telephone Switch Bell

Terminal P is connected to one of the primary terminals in transmitter, and the other primary terminal in transmitter to E.

The terminals S are connected to secondary terminals in transmitter; the other connections are as shown.

In calling up or answering a subscriber the button W E is pressed. This brings the spring S into contact with plate v, connected to terminal C. From spring S the current goes direct to line.

In calling up the exchange or giving the "cut-off" signal, the button B^k is pressed. This presses both the springs S' S'' back; S' into contact with plate v', which is connected to x'' and Z, and S'' into contact with v'', which is connected with v, and so to C.

The path of the current is now as follows:—From C to plate v, plate v'' and spring s'' to E, returning to terminal L, spring S, top bracket x, spring S', and plate v' to Z.

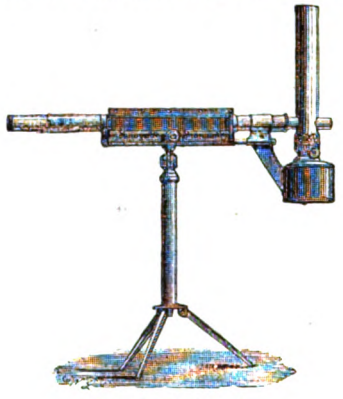
The passage of the incoming ringing current is as follows:—Terminal L, spring S, bracket x, spring S', bracket x', contact post in bell (when the telephone is on the hook the contact a is broken, and b closed), bell coils to hook lever centre, contact b, and then to E, as shown.

When the telephone is in use the current follows the same path as far as the contact post, when it goes through contact a to lever, thence through telephone to terminal S and transmitter secondary, returning by second terminal to E, as shown.

The above apparatus was designed for Mr. Haworth, the electrician of the Lancashire and Cheshire Telephone Company, he sketching his requirements for Mr. Volk.

MR. SABINE'S PHOTOMETER.

Mr. Sabine has lately constructed a new photometer, which is shown in perspective in the figure. The stand supports a straight tube, at one end of which is an eye-piece and at the other a paraffin lamp. The middle portion of the tube is cut away, and has slipped over it a collar, to which a frame is attached, carrying a wedge of neutral tinted glass, adjustable by a rack and pinion. Inside the collar is fixed transversely a disc of ground opal glass, which the paraffin flame illuminates to a known degree. This disc constitutes the field of comparison, the illumination of which is adjustable by means of a series of diaphragms of known aperture placed at the end near to the paraffin flame. At the side between the wedge and the collar which carries it is a narrow pane of ground opal glass, just behind which a small mirror is fixed at an angle of 45deg. to the axis of the tube. This mirror is supported from the centre of the transverse opal disc in such a manner that the support is hidden from the observer by the mirror itself—an arrangement which ensures the apparent juxtaposition of the illuminated surfaces which have to be compared. The light to be measured is placed on the right-hand side of the photometer,



Sabine's Photometer.

and the collar, with the wedge turned so that the light falls normally upon the face of the wedge, passes through the wedge, through the pane of opal glass, and is incident upon the mirror, which reflects a portion of it to the eye of the observer. The wedge is shifted to interpose a greater or less thickness of the absorbing medium, till a balance is obtained, that is until the apparent illumination of the mirror is equal to that of the field of comparison, in the middle of which it is seen. If the range of the wedge is insufficient to admit of this, the degree of illumination of the field is altered by means of the diaphragms, and the wedge then adjusted.

The employment of glass wedges from photometric comparisons is not new, having been already used by both Xavier de Maistre and Quetelet; but no practical photometer, based upon this method, has hitherto been constructed. The employment of diaphragms for increasing the range of the wedge is found to work well, and to enable the observer to adjust the illumination of the field with exactitude; the bright part of the paraffin flame being, of course, kept opposite to and so as to well cover the diaphragm aperture.

A table is constructed giving for each position of the wedge and for each diaphragm the value in standard candles of any light placed at one metre distance from the instrument; and if the light be placed at any other distance the number in the table has simply to be multiplied by the square of the actual distance in metres.

For ascertaining approximately the amount of light which passes through any given coloured glass—such, for example, as orange glass—the eye-piece is furnished with a rotary disc containing small panes of white and different coloured glasses, either of which can be interposed at pleasure.

This photometer is made by Messrs. Elliott Brothers in two forms, one for use as a portable photometer, as shown in the figure, and the other on a more solid stand for laboratory purposes.

MORE GAS.

Whatever angry feelings may at first have been aroused among the owners of gas property by the intrusion of the electric light must now, we should imagine, give place to sentiments nearly akin to gratitude. The scare which temporarily depreciated the price of gas shares to about half their market value has been followed by an equivalent rise and a steady tone which is not likely to give way to panic again in a hurry. But this is not all; the competition of the electric light has created a demand for better illumination, and this means the consumption of more gas. The public, we have heard it stated, have become quite demoralised in the matter of street lighting, and having tasted the luxury of a well lighted thoroughfare, will not again submit to anything less luxurious in place of it. We are not in the secrets of the gas manufacturers, but nobody can walk along either of the two great footways which lead from the City to the West End without feeling perfectly convinced that the consumption of gas must have greatly increased since electricity essayed to extinguish it. The gas corporations are not likely to be making this great display experimentally, or at a loss, as is spitefully alleged of one or two electric lighting companies; and we may, therefore, conclude that the receipts of the former have of late been greatly augmented. For this they have to thank the electric light, and we hope they are grateful.

The exhibition of gas lighting appliances at the Crystal Palace is another boon which the gas companies owe to the electric light. Nominally it is a competitive exhibition between the two systems of lighting, the old and the new; but in reality the gas people have the field almost all to themselves, some well known electric lighting engineers even going so far as to exhibit gas lighting appliances only, and not their electric lighting inventions. The few exhibits of electrical illumination on view are of little account and are not calculated to depress the spirits of shareholders in the old companies. Whether this is a wise piece of self-denial on the part of the electric lighting interests time alone will show; certain it is the gas interests are just now in the ascendant at the Crystal Palace, and nobody can blame them for making the most of the occasion. There are several useful lessons to be learnt at this exhibition, however, which those who are interested in the future of electric lighting may profit by, and we will mention a few of them.

First of all, gas is here at its best. We see what it can do. Not that anybody doubted we could have more light by consuming more gas; but the gas engineers appear to have thought it necessary to remove the doubt if it existed. At a profligate expenditure of gas, they have lit up this vast edifice splendidly. But this is all. There is no evidence of economy in the general arrangement, the aim being to display great lights; and the impression left on one's mind is that the exhibitors only wanted to convince us that, if we would pay for a big light, we could have it. This tells in favour of electricity, for if the public will pay for a big light they can certainly have electricity as cheaply as gas—the cheapness being on the side of gas when small lights or small quantities of light are in question. In this relation we may also state that the devices for economising consumption are of the poorest, testifying to general incredulity in the matter of economy, and to the willingness of the public to pay handsomely for what it likes. Gas manufacturers ought to be the best authorities on a point of this sort, and electric lighting manufacturers will not fail to take note of it. Beyond the curious device of putting two gas flames together, and getting more than double the light out of them—a device which most people seemed to regard as an attempt to make believe that twice one are three—beyond this, we say, there is hardly anything to encourage a careful housekeeper in the hope of reducing his gas bill. On the whole, indeed, he comes away with the conviction that if he wants a better light he must pay more for it, which is, at present, precisely what electric lighting engineers are saying.

Secondly, in the matter of candle-power, there is just as much looseness of statement here in respect to gas as there has been anywhere with regard to electricity. Candle-power we suspect in many instances is estimated by the known consumption of gas, which is much the same as measuring an arc light by the horse-power employed to maintain it. Some of the monster lights which have been much talked about certainly do not show here to advantage. They are eminently calculated—one at least was so—to illuminate a ceiling, or to set it on fire; but as for lighting anything below they do not even make the attempt. They are, in fact, gas furnaces, with

Digitized by Google

all the objections of redness, an obstructive burner, and the central mass of the flame giving off no light worth speaking of. The candle-power conspicuously marked on lamps such as these will only confirm public suspicion as to the illusory character of candle-powers in general. In this respect gas is evidently as great a sinner as its rival.

Of the street lamps on view there are several of considerable merit as regards illumination, and from the design of which electric lighting engineers might learn a wrinkle or two. Especially it is noticeable that artistic taste has been bestowed on these lamps; they are agreeable to look upon as well as useful, a point which has been not only overlooked but rudely defied by some electric lighting engineers. The public may consent to have their streets temporarily disfigured for an experiment, but for permanent installations beauty as well as utility must go together if the public are to be won over. To this fact the gas engineers appear to be fully alive, and our clients would do well to follow their example.

On æsthetic grounds, as well as on some other to be referred to immediately, we cannot refrain from contrasting the two classical courts, illuminated the one by gas the other by electricity. Both are specialties. The latter makes a merit, so it would seem, of employing a naked light which nobody can endure to look upon intentionally, and which it would really be a charity to prevent being seen accidentally; the other has its lights naked also, partly to show their purity, partly, no doubt, to enhance the general effect. The fittings of these are very chaste, and in keeping with the architecture; the fittings of the light in the other court cannot be seen for the dazzle, and probably they are not worth examining. The general effect is unmistakably in favour of gas, though the volume of light, and perhaps its cost, may be all on the side of electricity. For this result the proprietors of the electric light have only their want of taste and judgment to blame.

The gas light just referred to was the perfection of lighting—save in one particular; it costs some trouble, and the public we know will not take trouble. The purifying medium has to be replenished frequently, and some patience exerted before it acts. These, we think, are fatal objections, and we mention them as applicable to electric lights that require attention from private users. "How would the servants be able to dust those globes?" was the very practical question of a lady whom we overheard interrogating the exhibitor of some meretricious lamps buried in fragile inutilities of glass and china. She shook her head when told that the globes could be removed quite easily. Probably the lady housekeeper has her own view as to what is easy, and she certainly ought to be consulted.

Lastly, the condition of the atmosphere at the Crystal Palace is proof that a great illumination of gas cannot be obtained without serious danger of one sort or other. Ventilation is obtained only by opening every available window, and the discomfort occasioned by the consequent draughts is so great that the attendants who have to remain in one spot and uncovered are objects of general pity. This exhibition, if encouraging to the gas interests, should be very instructive to the promoters of electric lighting.

ANSWER TO CORRESPONDENT.

P. A.—The Morse code is in use in France.

TECHNICAL SCHOOLS.

I.

The School of Telegraphy and Electrical Engineering.

During the past two years many parents, anxious to find an opening for the future work of their sons, have looked with favour upon the prospects of electrical engineers. We have received a large number of letters—and, indeed, are almost daily receiving letters—asking for advice and suggestions as to where a youth can obtain the fundamental information which ought to constitute the groundwork of an electrical engineer's education. So far as we know the following colleges and schools profess to give this kind of technical information:—

COLLEGES.

Cavendish Laboratory, Cambridge	Professor Lord Rayleigh, F.R.S.
Glasgow University	Professor Sir W. Thomson, F.R.S.
King's College, London	Professor W. G. Adams, F.R.S.
University College, London	Professor Carey Forster, F.R.S.
Queen's College, Liverpool	Professor O. J. Lodge, D.Sc.
University College, Nottingham	Professor W. Garnett, M.A.
University College, Bristol	Professor S. Thompson, D.Sc.

SCHOOLS.

School of Telegraphy and Electrical Engineering	12, Princes-street, Regent-street.
Hammond Company's School.	2, Red Lion-square.
Crystal Palace School	Sydenham.
City Guilds' Institute (Professor W. E. Ayrton, F.R.S.)	City Schools, Cowper-street, E.C.
College of Science (Principal, A. Jamieson)	Bath-street, Glasgow.

No doubt there are other places where the student can obtain good tuition, but we can only speak of those we know. Of the schools, the one we have mentioned at the head of this article is the oldest, and, therefore, historically, should be mentioned first. We presume that parents and students are only anxious to obtain a general idea of these institutions, and to be satisfied that they are supplied with the necessary apparatus, and that the work is carried on under sufficiently good lecturers and tutors. With regard to the school under notice we may safely state that the apparatus is ample, and of the most recent construction, and that the lecturing staff is larger than is ordinarily the case with a given number of students. Fig. 1 will give some idea of the interior of the principal work room, which room is sometimes used as a lecture room. The large supply of testing apparatus admits of a good deal of individual work, under the supervision of demonstrators. The work of the school is carried out in two lines, one intended to educate aspirants to various positions in the telegraph world, and more especially, perhaps, in the large cable companies. A large portion of the cable companies' staffs have received their early training in this school. Special apparatus is to be formed for this special work. Thus, with the exception perhaps of Glasgow University, this institution is the only one where an artificial cable is to be found. We believe that almost as soon as Mr. Cromwell Varley, F.R.S., had designed his system of condensers and resistances to represent a cable, the school obtained an artificial cable in order that the students might as nearly as possible work under similar conditions to those which hold in working a real cable. It will be remembered that this school exhibited at the late Crystal Palace Exhibition one of Sir W. Thomson's syphon recorders, an instrument which the necessities of long cable telegraphy has called into existence. It will be gathered from these remarks that the telegraphic department is most complete. The same may be said with regard to the telephonic apparatus. Again, in that branch of electrical science which is now so prominent, the student is not left to verbal description or diagrams in order to get his ideas of a lamp or machine, but has specimens of the more important lamps, &c., before him. These he dissects in order to become acquainted with every part, and with the particular function of each part. He tests the parts—he tests the whole. Fig. 2 shows portions of various rooms, such as the machine room, containing Siemens, Brush, and Gramme machines, the

Digitized by Google

chemical laboratory, the room for experimenting with secondary batteries, &c. The latter rooms are used by the more advanced students, and a good deal of original work indicated by the lecturers, or suggested by the students themselves, is carried out, and we hear this branch of the training will be developed to a still greater extent. The senior lecturer, upon whom, indeed, the scientific organisation has devolved since the opening of the school, is Mr. Desmond FitzGerald.

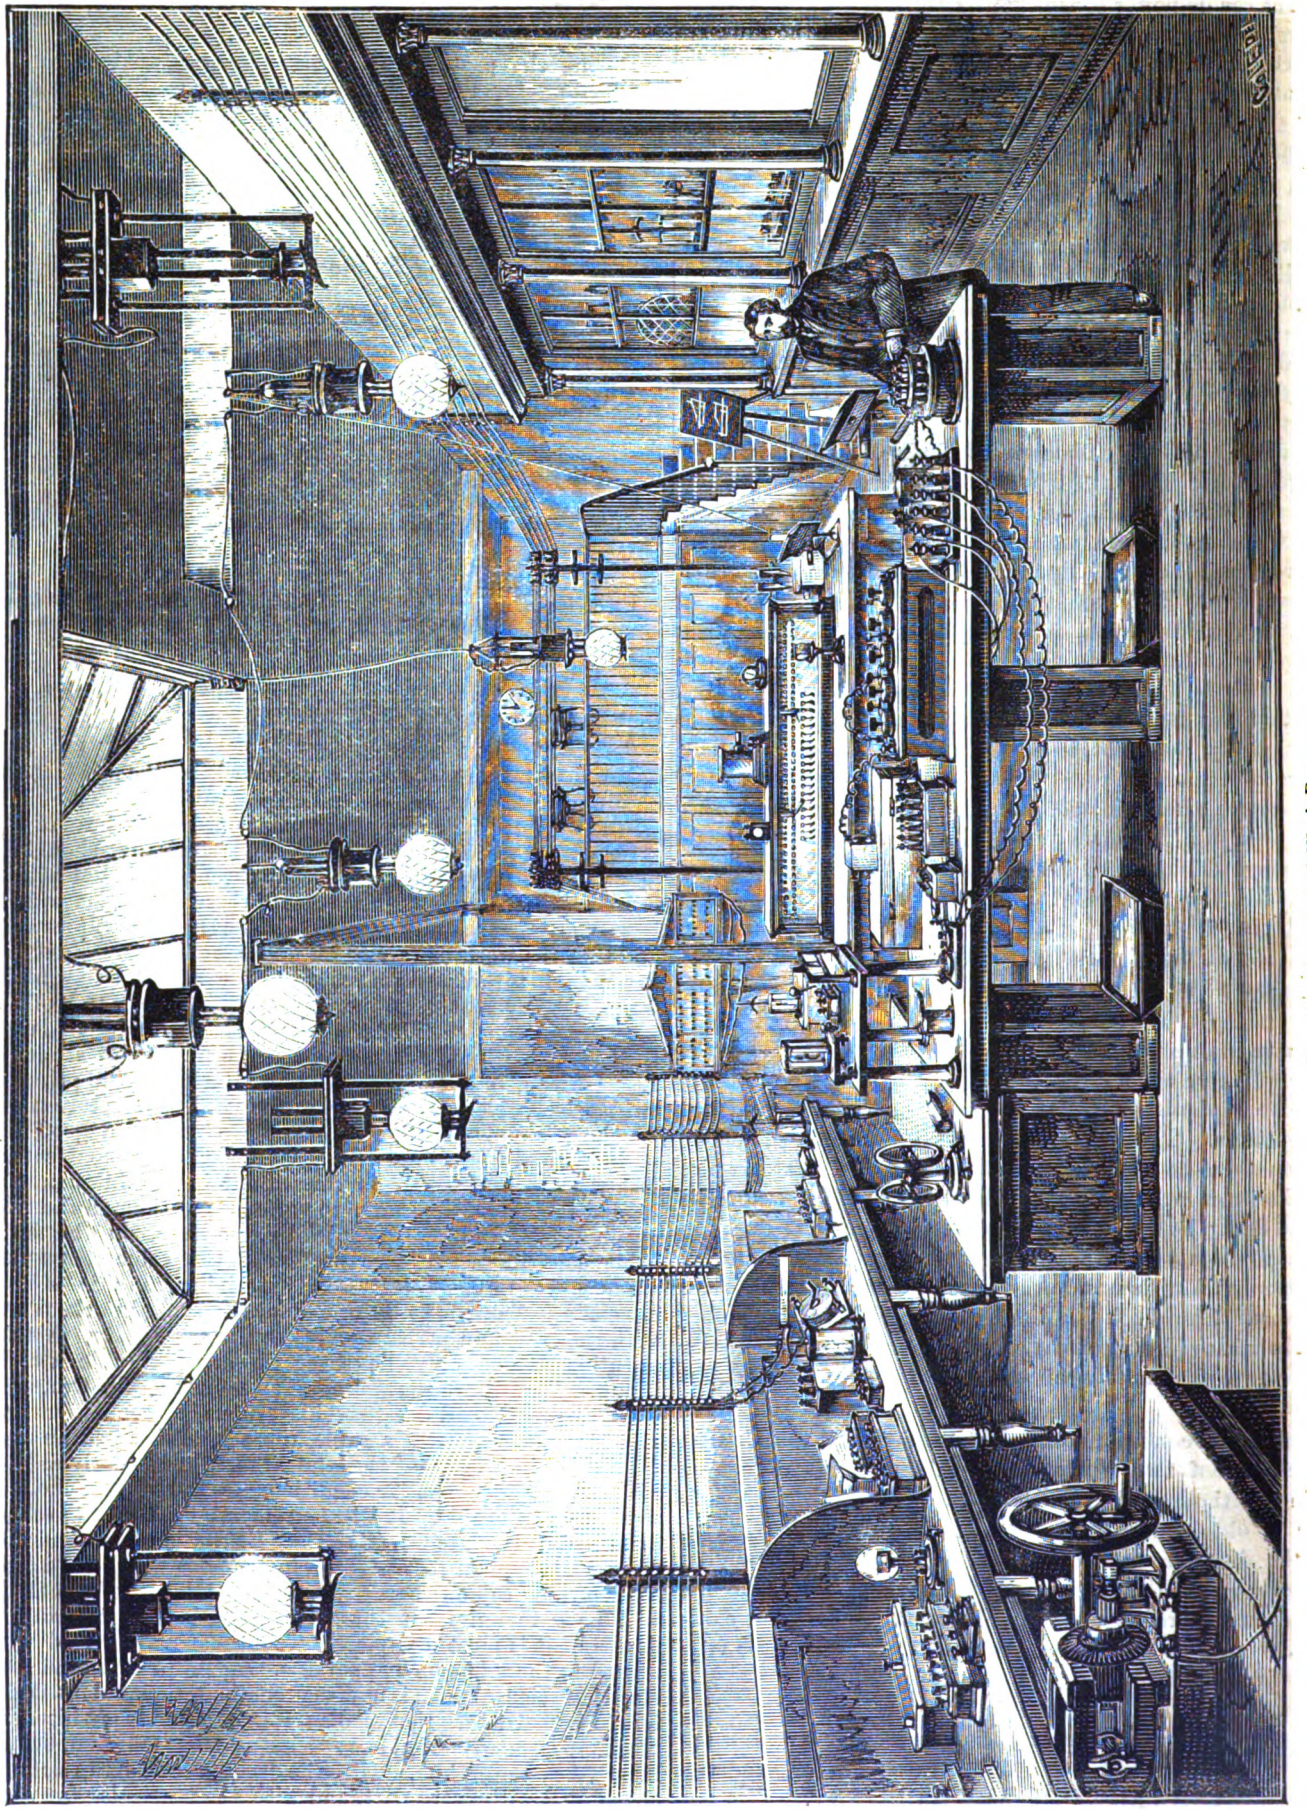

FIG. 1.—The principal Work Room.

Digitized by Google

The school was founded by the late Mr. Lundy, and was at first devoted to the training of operators for land lines, but from the first insisted upon the necessity of a theoretical, as well as a practical, training for such as wished to become more than mere automatons. The extension of cable work created a field for a higher class of men, and the development of the electric light holds still greater inducements for men to obtain a more thorough knowledge of electrical theory and

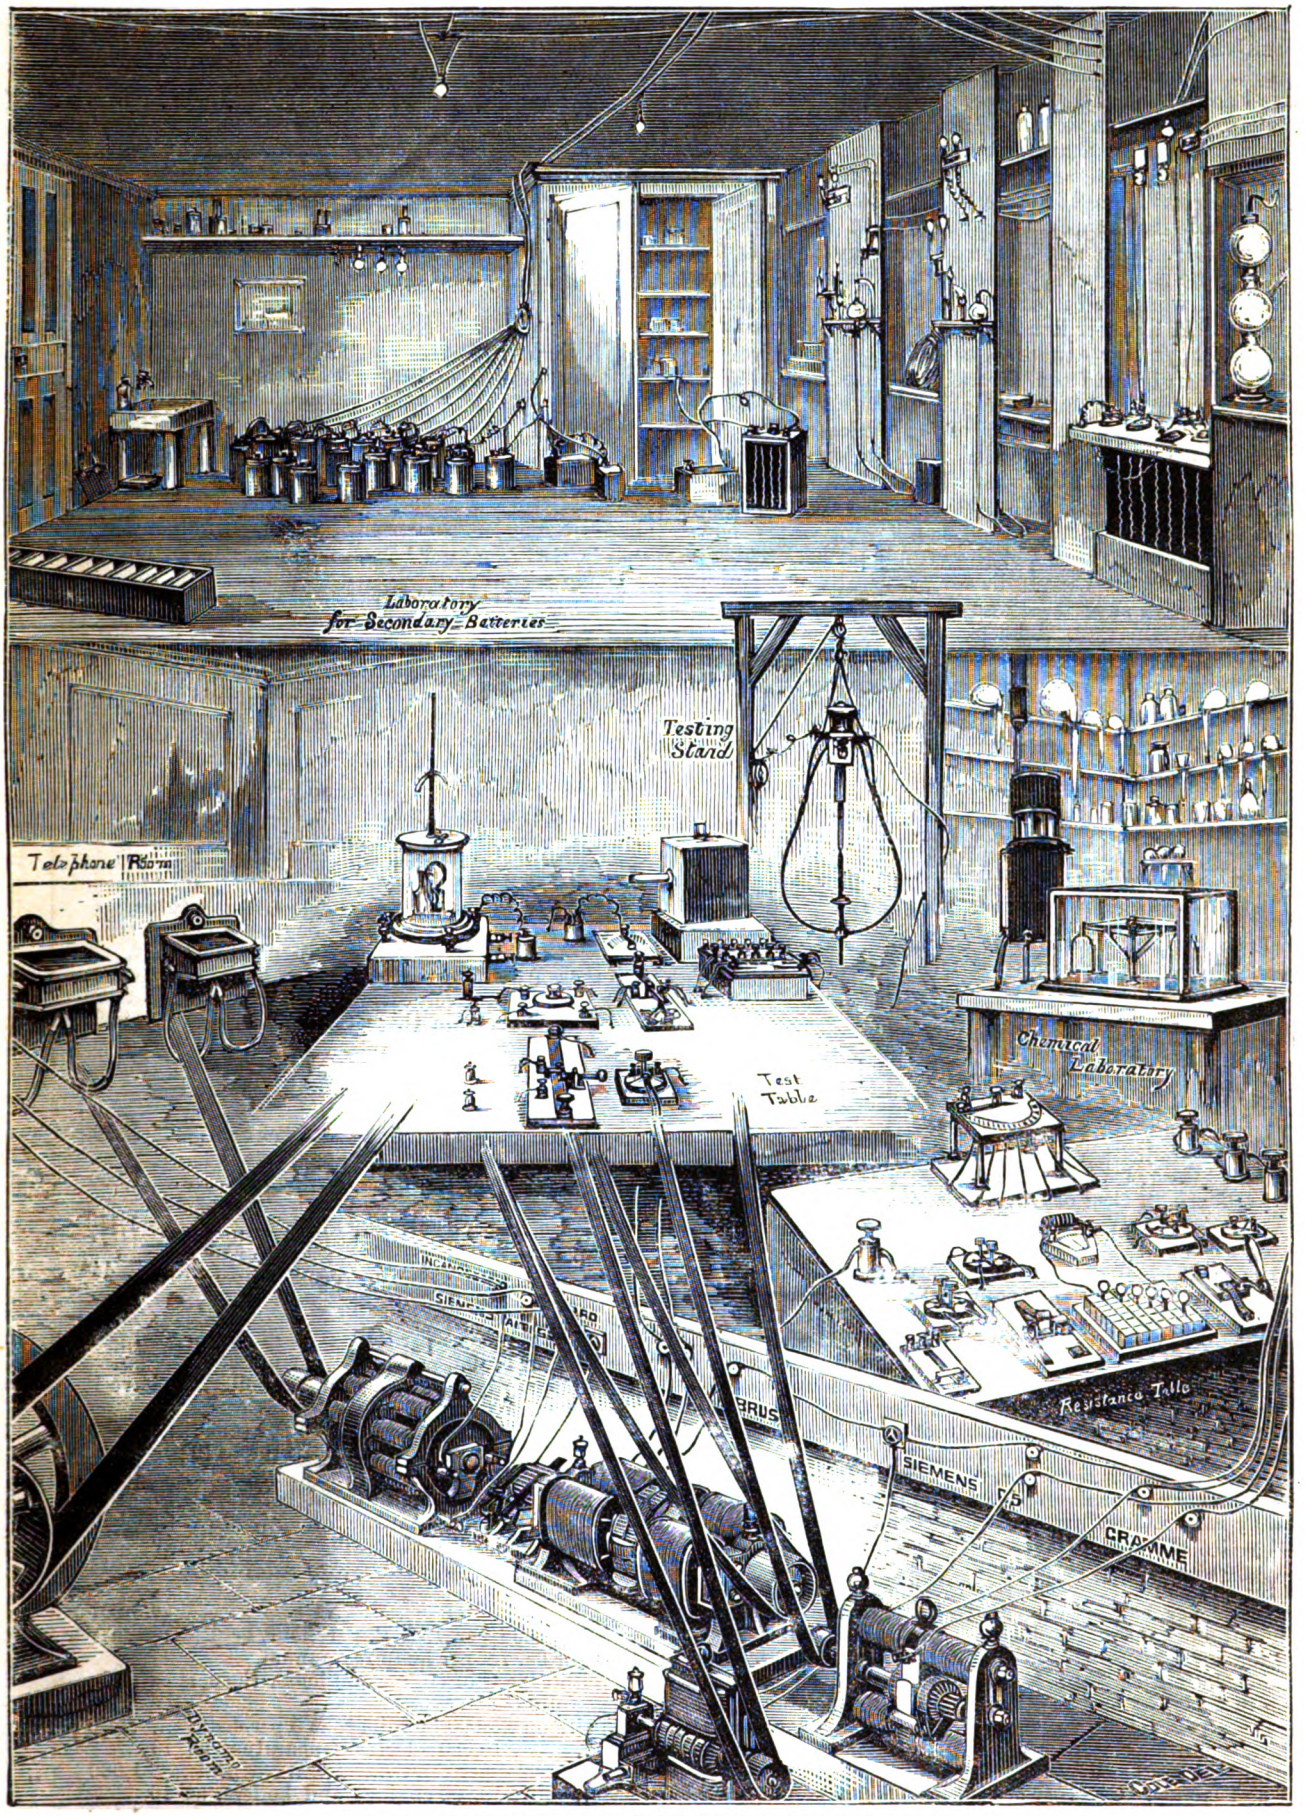

FIG. 2.—Machine Room, Chemical Laboratory, Battery Room, &c.

Digitized by Google

practice. The course extends over a period of nine or twelve months, and, besides the practical work, includes lectures on electricity, heat, the steam engine, chemistry, &c., so far as these subjects are calculated to assist the student in his practical work. We have known the school for many years, and we have known personally many of the men trained therein, and perhaps an opinion expressed under these conditions is a little more satisfactory than one by a reporter who rushes over the place and out again, and whose impressions are, we opine, almost valueless. There is no doubt that a strenuous attempt has been made to supply everything that a student can possibly require. The rest depends much upon the student himself. If he means work there is everything in his favour. If he will not work, and is careless and indifferent, he suffers accordingly. A lecturer is not a schoolmaster, nor are these pupils schoolboys, nor can scholastic discipline be resorted to. A number of men from the school have done, and are doing, good work, both in telegraphy and in electric lighting. Our columns can show that some of the students have sufficient confidence in their knowledge to enter the field of literature. In order to obtain an idea of the students' progress, periodical examinations are held, and at the end of their course a certificate used to be—and we suppose is now—given, based upon the result of the examinations. The aim, however, is to prepare the pupils for practical work, and not to cram them with superficial knowledge, that they may pass this or that examination. The general organisation of the school is carried on under the able superintendence of Mr. T. J. Jones, supplemented by that of the secretary, Mr. W. N. Tiddy.

BOROUGH OF SHEFFIELD.

Electric Lighting Act, 1882.—Preliminary Report of Conrad W. Cooke, M.S.T.E. & E.

(concluded from page 281.)

I will now consider the probable cost of working such an installation, inclusive of charges for management as well as for interest on capital. I will divide these charges under four heads, viz.:—

I.—Cost of Production.
II.—Cost of Maintenance.
III.—Cost of Management.
IV.—Interest on Capital.

1. Production.

The cost of production is made up of three principal items:—

1. Cost of Coal.
2. Cost of Oil, Stores, &c.
3. Wages.

Cost of Coal.

Taking the price of engine coal delivered in Sheffield at 7s. per ton, and estimating that the compound non-condensing engines with Lancashire boilers (A) will consume 2·71b. of coal per horse-power per hour, we have an expenditure of £1,582 per annum.

If, however, condensing engines with similar boilers be employed, the cost for production will be less on account of the greater economy of working, they consuming but 2·3lb. of similar coal per horse-power per hour, the cost will therefore be £1,347 per annum.

The saving of coal is, however, to a certain extent, neutralised by the extra cost of maintenance added to a larger interest on capital by reason of the greater prime cost of the engines.

Lastly, by the employment of "Locomotive" boilers—by which a great saving of space is effected, and steam may be got up in the shortest possible time—a still less quantity of coal per horse-power per hour is consumed, being at the rate of about 2lb., but it must be borne in mind that these boilers are not suited for burning ordinary engine coal, but require a more expensive fuel, such as Tanfield Moor or coal of similar quality, costing in Sheffield probably as much as 9s. per ton, and here again the extra capital involved raises the cost of working and the interest to a price which, unless a saving of space be of great importance, hardly justifies the adoption of this class of boiler and engine. The cost of coal in this case would be £1,507 per annum.

Oil Stores, &c.

I now come to that item in the cost of production which refers to oil stores, and this may be fairly estimated at about £4 16s. per week, or £250 per annum.

Wages.

With respect to wages the following staff will be sufficient to work such an installation as is referred to in this report:—

One electrical foreman, at £12 10s. per month	£150	per annum.
Three engine drivers, each at £8 15s.	315	,,
Six firemen, each at £6 10s.	470	,,
One boy, at £1 15s.	21	,,
Total for wages	£956	

Summarising the foregoing figures, we get the following results for the employment of the type of engine and boiler referred to in column A in the tabulated summary of capital:—

Coal	£1,582	per annum.
Oil and stores, &c.	250	,,
Wages	956	,,
	£2,788	

that is to say, ·178 pence per I.H.-P. per hour, *i.e.*, ·022 pence per hour; or 5s. 6½d. per lamp per annum.

Employing type B of engine and boiler, we have the following cost of production:—

Coal	£1,347	per annum.
Oil and Stores, &c.	250	,,
Wages	956	,,
	£2,583	

that is, ·163 pence per hour, = ·02 pence per lamp per hour, or 5s. lamp per annum.

With type C of engine and boiler, the cost of production will be as follows:—

Coal	£1,507	per annum.
Oil, Stores, &c.	250	,,
Wages	956	,,
	£2,713	

that is, ·174 pence per I.H.-P. per hour, = ·022 pence per lamp per hour, or 5s. 6d. per lamp per annum.

II. Maintenance.

The expenses of maintenance of an electric lighting installation are made up of the following items:—

1. Repairs of buildings,
2. ,, electric apparatus,
3. ,, engines and boilers,
4. ,, distributing plant,

and these I would estimate at about 5 per cent. per annum on the first cost respectively of the buildings and distributing plant, and 10 per cent. on that of the electric apparatus and motive power.

Upon this principle of estimation the following will be the cost of maintenance of the installation of type A if engine and boiler be adopted:—

Repairs on £5,000 buildings, at 5 per cent.	£250	per annum.
,, £10,000 electric apparatus, at 10 per cent.	1,060	,,
,, £11,180 engines and boilers, at 10 per cent.	1,118	,,
,, £8,880 distributing plant, at 5 per cent.	444	,,
	£2,872	

which is ·184 pence per I.H.-P. per hour, or ·023 pence per lamp per hour, or 5s. 9d. per lamp per annum.

Employing type B of engine and boiler, we have the following cost of maintenance:—

Repairs on £5,000 buildings, at 5 per cent.	£250	per annum.
,, £10,600 electric apparatus, at 10 per cent.	1,060	,,
,, £15,530 engines and boilers, at 10 per cent.	1,553	,,
,, £8,880 distributing plant, at 5 per cent.	444	,,
	£3,307	

= ·212 pence per I.H.-P. per hour, or ·026 pence per lamp per hour, or 6s. 7d. per lamp per annum.

With type C of engine and boiler the cost of maintenance will be as follows:—

Repairs on £5,000 buildings, at 5 per cent.	£250	per annum.
,, £10,600 electric apparatus, at 10 per cent.	1,060	,,
,, £16,700 engines and boilers, at 10 per cent.	1,670	,,
,, £8,880 distributing plant, at 5 per cent.	444	,,
	£3,424	

Digitized by Google

i.e., ·219 pence per I.H.-P. per hour, which is at the rate of ·028 pence per lamp per hour, or 7s. per lamp per annum.

III.—MANAGEMENT:—

For the cost of management the sum of £500 may safely be assumed to cover all outlays under this head upon an installation of 10,000 incandescence lamps.

£500 per annum = ·32 pence per I.H.-P. per hour, *i.e.*, ·004 pence per lamp per hour, or 1s. per lamp per annum.

INTEREST ON CAPITAL.

Employing type A of engine and boiler, we have:—

Interest on £44,726, at 5 per cent., = £2,236 per annum, or ·143 pence per I.H.-P. per hour, *i.e.*, ·018 pence per lamp per hour, or 4s. 6d. per lamp per annum.

With type B of engine and boiler the capital being larger the interest is proportionately increased.

Interest on £49,511 at 5 per cent. = £2,475 per annum, which is = ·158 pence per I.H.-P. per hour, or = ·02 pence per lamp per hour, or 5s. per lamp per annum.

If type C be employed, the annual cost of interest on capital per lamp is about the same thus:—

Interest on £50,798 at 5 per cent. = £2,540 per annum, or ·162 pence per I.H.-P. per hour, *i.e.*, ·02 pence per lamp per hour, or 5s. per lamp per annum.

Summarising the above figures in a tabular form, we have the following table of the cost of working the installation, with the three types A. B. and C. respectively of engine and boiler:—

Working Cost.	Cost per lamp, using compound non-condensing engines and Lancashire boilers, consuming 2·7lb. of coal (at 7s.) per I.H.-P. per hour.		Cost per lamp, using compound condensing engines and Lancashire boilers, consuming 2·3lb. of coal (at 7s.) per I.H.-P. per hour.		Cost per lamp, using compound condensing engines and "locomotive" boilers, consuming 2lb. of coal (at 9s.) per I.H.-P. per hour.	
	Per hour.	Per ann. of 3,000h.	Per hour.	Per ann. of 3,000h.	Per hour.	Per ann. of 3,000h.
	pence.	s. d.	pence.	s. d.	pence.	s. d.
Production	·022	5 6½	·02	5 0	·022	5 6
Maintenance	·023	5 9	·026	6 6	·028	7 0
Management	·004	1 0	·004	1 0	·004	1 0
Interest on Capital at 5 per cent	·018	4 6	·02	5 0	·02	5 0
Total cost.....	·067	16 9½	·07	17 6	·074	18 6

The above figures indicate that the saving of coal effected by the adoption of condensing engines is not so great as the increase of working cost, due to repairs and interest on capital for an installation of this size, in a town like Sheffield, where coal can be had at an exceptionably cheap rate and, when it is considered, moreover, that, added to the above working cost, there must be a considerable item for the supply of condensing water, I do not feel justified in recommending the adoption in the present case of condensing engines, although in my opinion for very large installations, such as will be required when electric lighting for public and private purposes becomes general, there will be a most decided advantage in the employment of the most economical working power, even in places where coal is cheap.

It must be noted that the capital expenditure and working cost mentioned in this report are calculated on the assumption that the whole number of ten thousand lights are in action during the whole year's working of three thousand hours; or, in other words, that the producing plant has an annual demand upon it of thirty million lamp-hours; but this result can hardly by any possibility be attained in practice, and I should consider that the average would not exceed half that amount, for the number of lights in operation at any one moment depends upon a number of individual and local circumstances. Thus in a district (such as that proposed to be lighted in Sheffield) consisting mainly of shops and houses of business there will be great differences in the period during which the lights of different establishments are in operation. For example:—Some shops shutting up at 6 o'clock would turn out their lights at 6:15, many close at 8, and a large number at 10, while some remain open still longer. Banks, on the other hand, would shut off at 5 or half-past, and thus during the winter, while some might keep their lights running as long as nine hours others would be cut off after only one hour's working. Again, on Sunday, that is for a period equal to one-seventh of the year, or nearly 430 working hours, very few, if any, lights would be used in shops or houses of business, and the number would be reduced to what was required for domestic purposes. On the other hand, on dark, foggy days, and in places poorly lighted by daylight, the lights might be required during the whole of or for a large portion of the day, and in some establishments they might be kept going all night. All these considerations show that the demand upon the producing plant at any one hour would be different in different places, and also that it would be very variable from hour to hour.

Against, however, such exceptional demands must be set the fact that during the summer months the lights of some of the largest establishments would not be in use at all, while in all the duration of burning would be reduced as the days increased, and thus the annual working cost would be proportionately reduced.

Again, there must be expected to be some variation in the number of lights in operation in any one establishment. For example, in shops in which work is carried on after the establishment has been closed to the public, the lamps illuminating the windows and shop front would be shut off earlier than in the rest of the building; but it will be readily understood that the larger the installation driven from one connected system of conductors, whether deriving their electricity from one or more than one producing station, the more uniform will be the demand and the closer will it approximate to an average constant. Taking all these considerations together, I am inclined to think that, except on rare occasions affecting the whole community alike, such, for example, as a general illumination on an occasion of public rejoicing, there would never occur an instance of all the lamps being in action at the same time for many hours together.

I have in the earlier part of this report recommended the employment of electric lighting by incandescence for the *private* lighting of the district, for the reasons already stated. It must, however, be a matter for the subsequent consideration of the Corporation whether it will be advisable on their part or not to recommend to consumers the employment of any one system of incandescence lighting or special form of lamp. Of these there are four principal kinds, named respectively after their several inventors—the Swan, the Edison, the Lane-Fox, and the Maxim—each possessing distinguishing characteristics of its own.

It is, however, contrary to the provisions of the Electric Lighting Act of 1882, as it exists at the present date, for the Corporation, as undertakers, to specify or insist upon the consumers employing any particular form of lamp. On the other hand, it is highly desirable in the interests of the consumers, as well as for the success of the undertaking, that no apparatus be employed by consumers that shall either through failure or otherwise bring discredit on the undertaking.

To meet this, I would propose that the Corporation without in any way insisting on the employment of any special lamp, should encourage the adoption of a lamp best suited to the installation, either by offering certain advantages in the supply, or putting up of such lamps, or by the entering into of an arrangement with certain firms, local or otherwise, for the supply and fitting of those lamps which, in the opinion of the Corporation, are most suitable; such firms agreeing to supply and fit lamps at a price advantageous to the consumer in consideration for the recommendation and general guarantee of the corporation. It would in all cases be necessary to make it a condition of supply that no lamp or appliance of any sort be employed by a consumer that has not been previously approved of by the corporation or their scientific advisers. A provision of this sort, made solely in the interests of the general body of consumer, could not be, in the smallest degree, contrary to the spirit of the Electric Lighting Act, or of the rules of the Board of Trade, and would, I believe, meet with general approval. It is, moreover, a condition applicable and necessary alike to all systems of lighting in which a community of consumers is supplied from a common centre, and, therefore, is as necessary for gas lighting as for electric illumination.

As bearing upon the capital required for installation, as well as the cost of working the same, I may point out that the estimate hereinbefore set forth is based upon manufacturers' prices. It is probable, however, that with the keen competition which must accompany the extended adoption of electric lighting, such prices may be reduced, or considerable discounts allowed, thus reducing the capital required.

CONRAD W. COOKE.

CANTOR LECTURES.*

Dynamo-Electric Machinery.

BY PROFESSOR SILVANUS P. THOMPSON, B.A., D.SC., M.S.T.E.

Lecture III.—The Dynamo as a Motor.

(CONTINUED FROM PAGE 275.)

In my first lecture, I laid down the definition that dynamo-electric machinery meant "machinery for converting the energy of mechanical motion into the energy of electric currents, or *vice versâ*." In the two lectures which I have already had the honour of delivering, I have treated the dynamo solely in its functions as a generator of electric currents. In this third lecture I come to the converse function of the dynamo, namely, that of converting the energy of electric currents into the energy of mechanical motion.

An electric-motor, or, as it was formerly called, an electro-magnetic engine, is one which does mechanical work at the expense of electric energy; and this is true, no matter whether the magnets which form the fixed part of the machine be permanent magnets of steel or electro-magnets. Any one, in fact, of the four kinds of dynamos, can be used conversely as a motor, though, as we shall see, some more appropriately than others. But whether their field-magnets be of permanently magnetised steel or of temporarily magnetised iron, all these motors are electro-magnetic in principle; that is to say, there is some part either fixed or moving which is an electro-magnet, and which as such attracts and is attracted magnetically.

Every one knows that a magnet will attract the opposite pole of another magnet, and will pull it round. We know also that every magnet placed in a magnetic field tends to turn round and set itself along the lines of force. Let me, as a first illustration of this class of actions, exhibit to you the nature of the forces at work in the magnetic field. In the figure which I now throw upon the screen (an electrification of the action of a magnetic field on a magnetic needle), we have, in the figure which I now throw upon the screen (an illustration of the action of a magnetic field on a magnetic needle), we have, in the first place, a simple magnetic field produced between the poles of two strong magnets, one on the right, the other on the left. Between the two, confined forcibly at right-angles to the lines of force, I hold a small magnetic needle. Iron filings sprinkled in the field reveal the actions at work in a most instructive way. Faraday, who first taught us the significance of these mysterious lines of force, has told us that we may reason about them as if they tended to contract or grow shorter. Now, a simple inspection of the illustration on the screen will show that the shortening of the lines of force must have the effect of rotating the magnetic needle upon its centre, through an angle of 90deg., for the lines stream away on the right hand above, and on the left hand below, in a most suggestive fashion. It is not, therefore, difficult to understand that very soon after the invention of the electro-magnet, which gave us for the first time a magnet whose power was under control, a number of ingenious persons perceived that it would be possible to construct an electro-magnet engine in which an electro-magnet, placed in a magnetic field, should be pulled round; and, further, that the rotation should be kept up continuously, by reversing the current at an appropriate moment. As a matter of fact, a mere coil of wire, carrying a current, is acted upon when placed in the magnetic field, and is pulled round as a magnet is (an illustration of this was given). The magnetic field is, as before, produced between the ends of two large magnets. The two round spots are two holes drilled in the sheet of glass, where the wire which carried the current came up through the glass and descended again. You will notice how the lines of iron filings, which would, if there were no current, run simply across from left to right, are bent out of their course. If these lines could shorten themselves, they must, of necessity, twist the loop of wire round, and cause it to set at right angles to its present position.

On this very principle was constructed the earliest electric-motor of Ritchie, so well known in many forms as a stock piece of electric apparatus, but little better in reality than a toy.

A great step in advance was made by Jacobi, who, in 1838, constructed the multi-polar machine. This motor, which Jacobi designed for his electric boat, had two strong wooden frames, in each of which a dozen electro-magnets were fixed, their poles being set alternately. Between them, upon a wooden disc, were placed another set of electro-magnets, which, by the alternate attraction and repulsion of the fixed poles, were kept in rotation, the current which traversed the rotating magnets being regularly reversed at the moment of passing the poles of the fixed magnets, by means of a commutator consisting, according to Jacobi's directions, of four brass-toothed wheels, having pieces of ivory or wood let in between the teeth for insulation. Jacobi's motor is, in fact, a very advanced type of dynamo, and differs very little in point of design from one of Wilde's most successful forms.*

A still earlier rotating apparatus, and, like Ritchie's motor, a mere toy, was Barlow's wheel, described in 1823. This instrument, interesting as being the forerunner of Faraday's disc dynamo, is the representative of an important class of machines, namely, those which have a sliding contact merely, and need no commutator.

A fourth class of motors may be named, wherein the moving part, instead of rotating upon an axis, is caused to oscillate backwards and forwards. Professor Henry, to whom we owe so much in the early history of electro-magnetism, constructed, in 1831, a motor with an oscillating beam, alternately drawn backwards and forwards by the intermittent action of an electro-magnet. Dal Negro's motor of 1833 was of this class; in it a steel rod was caused to oscillate between the poles of an electro-magnet, and caused a crank, to which it was geared, to rotate in consequence. A distinct improvement in this type of machine was introduced by Page, who employed hollow coils or bobbins as electro-magnets, which, by their alternate action, sucked down iron cores into the coils, and caused them to oscilate to and fro. Motors of this kind form an admirable illustration of one of the laws of electro-magnetics, first formulated by Gauss, but developed later by Maxwell, to the effect that a circuit acts on a magnetic pole in such a way as to make the number of magnetic lines of force that pass through the circuit a maximum. Once more I have recourse to iron filings to illustrate this abstract proposition of electric geometry.

In the illustration before you the north pole of a bar magnet is placed opposite a circuit or loop of wire traversed by a current, and which comes up through the glass at the lower hole, and descends at the upper hole. The tendency to draw as many as possible of the magnet's lines of force into the embrace of the circuit is unmistakable. If now we reverse the current, what do we find? that the magnet's lines of force, instead of being drawn in, are pushed out. In fact, in one case, the pole is attracted, in the other repelled.

Page's suggestion was further developed by Bourbouze, who constructed a curious motor, which looks uncommonly like an old type of steam engine. We have here a beam, crank, fly-wheel, connecting-rod, and even an excentric valve-gear and a slide valve. But, for cylinders, we have four hollow electro-magnets; for pistons, we have iron cores, that are alternately sucked in and repelled out; and, for slide valve, we have a commutator, which, by dragging a pair of platinum-tipped springs over a flat surface made of three pieces of brass separated by two insulating stripe of ivory, reverses at every stroke the direction of the currents in the coils of the electro-magnets. It is really a very ingenious machine, but, in point of efficiency, far behind many other electric motors. Unfortunately, it does not do to design dynamo-electric machinery on the same lines as steam-engines.

Yet a fifth class of electric motors owes its existence to Froment, who, fixing a series of parallel iron bars upon the periphery of a drum, caused them to be attracted, one after the other, by an electro-magnet or electro-magnets, and thus procured a continuous rotation.

Lastly, of the various types of motor we may enumerate a class in which the rotating portion is enclosed in an excentric frame of iron, so that as it rotates, it gradually approaches nearer. Little motors, working on this principle of "oblique approach," were invented by Wheatstone, and have long been used for spinning Geissler tubes, and other light experimental work. More recently, Trouvé and Wiesendanger have sought to embody this principle in motors of more ambitious proportions, but without securing any great advantage.

It would be impossible, within the limits of a lecture, to deal with a tithe of all the various stages of discovery and invention, and if it were my intention to deal with the subject from the historical point of view, I might speak of many interesting and curious machines that have from time to time been tried. I might tell you how Page, after inventing his machine in 1834, succeeded, in 1852, in constructing a motor of such a size that he was able to drive a circular saw and lathe by it. I might describe the electric-motor of Davidson, which, in 1842, enabled him to propel a carriage, at the speed of four miles an hour, between Edinburgh and Glasgow. I might describe the engine, built in 1849, by Soren Hjörth, at Liverpool, which was of ten horse-power.

All these early attempts, however, came to nothing, for two reasons. At that time there was no economical method of generating electric currents known. At that time, moreover, the

* Reprinted from the *Journal of the Society of Arts*.

* Wilde's is, however, designed as a generator. Jacobi's, on the contrary, was designed as a motor; though, of course, it would generate currents if driven round by mechanical power.

Digitized by Google

great physical law of the conservation of energy was not recognised, and its all-important bearings upon the theory of electric machinery were not available.

While voltaic batteries were the only available sources of electric currents, economical working of electric motors was hopeless. For a voltaic battery, wherein electric currents are generated by dissolving zinc in sulphuric acid, is a very expensive source of power. To say nothing of the cost of the acid, the zinc—the very fuel of the battery—costs more than twenty times as much as coal, and is a far worse fuel; for whilst an ounce of zinc will evolve heat to an amount equivalent to 113,000 foot-pounds of work, an ounce of coal will furnish the equivalent of 695,000 foot-pounds.

The fact, however, which seemed most discouraging, and which, if rightly interpreted in accordance with the law of conservation of energy, would have been found to be (on the contrary) a most encouraging fact, was the following:—If a galvanometer was placed in the circuit with the electric motor and the battery, it was found that when the motor was running it was impossible to force so strong a current through the wires as that which flowed when the motor was standing still. Now, there are only two causes that can stop such a current flowing in a circuit; there must be either an obstructive resistance or else a counter electromotive force. At first, the common idea was that, when the motor was spinning round, it offered a greater resistance to the passage of the electric current than when it stood still. The genius of Jacobi enabled him, however, to discern that the observed diminution of current was really due to the fact that the motor, by the act of spinning round, began to work as a dynamo on its own account, and tended to set up a current in the circuit in the opposite direction to that which was driving it. The faster it rotated the greater was the counter-electromotive force (or "electromotive force of reaction") which was developed. In fact, the theory of the conservation of energy requires that such a reaction should exist.

We know that, in the converse case, when we are employing mechanical power to generate currents by rotating a dynamo, directly we begin to generate currents—that is to say, directly we begin to do electric *work*—it immediately becomes much harder work to turn the dynamo than is the case when no electric work is being done. In other words, there is an opposing reaction to the mechanical force which we apply in order to do electric work. An opposing reaction to a mechanical force may be termed a "counter-force." When, on the other hand, we apply (by means of a voltaic battery, for example) an electromotive force to do mechanical work we find that here, again, there is an opposing reaction, and an opposing reaction to an electromotive force is a "counter-electromotive force."

The experiment of showing the existence of this counter electromotive force is a very easy one. All one requires is a little motor, a few cells of battery, and a galvanometer. The galvanometer I shall use to-night is one which I brought out some years ago, and which has proved itself very convenient for lecture work, because it can be put into any ordinary lantern and projected on the screen. I have here, as a battery, four small accumulators of the Faure-Sellon-Volckmar type, and I have connected them with a little motor, also of my own design, the current being arranged so as to run through the galvanometer. I hold the spindle of the motor fast, so that it cannot rotate, and you see that the pointer of the galvanometer indicates 44deg. I now release the motor; it begins to rotate, and as its speed increases, you observe the needle descend the scale to 23deg., and eventually to about 15deg. If I load the motor and cause it to slacken speed, the needle at once returns.

The existence of this counter-electromotive force is of the utmost importance, in considering the action of the dynamo as a motor, because upon the existence and magnitude of this counter-electromotive force, depends the degree to which any given motor enables us to utilise electric energy that is supplied to it in the form of an electric current. In discussing the dynamo as a generator, I pointed out many considerations, the observance of which would tend to improve the efficiency of such generators. It is needless to say that many of these considerations, such as the avoidance of useless resistances, unnecessary iron masses in cores, and the like, will also apply to motors. The freer a motor is from such objections the more efficient will it be, but the efficiency of a motor in utilising the energy of a current depends not only on its efficiency in itself but on another consideration, namely, the relation between the electromotive force which it itself generates when rotating and the electromotive force—or, as some people call it, the electric pressure—at which the current is supplied to it. A motor which itself in running generates only a *low* electromotive force cannot, however well designed, be an *efficient* or economical motor when supplied with currents at a *high* electromotive force. A good low-pressure steam engine does not become more "efficient" by being supplied with high-pressure steam; nor can a high-pressure steam engine, however well constructed, attain a high efficiency when worked with steam at low pressures. Analogous considerations apply to dynamos used as motors. They must be supplied with currents at electromotive forces adapted to them. Even a perfect motor—one without friction or resistance of any kind—cannot give an "efficient" or economical result, if the law of efficiency is not observed in the conditions under which the electric current is supplied to it.

Now it can be shown, mathematically, that the efficiency with which a perfect motor utilises the electric energy of the current depends upon the ratio between this counter-electromotive force and the electromotive force of the current that is supplied by the battery. No motor ever succeeds in turning into useful work the whole of the currents that feed it, for it is impossible to construct machines without resistance, and whenever resistance is offered to a current part of the energy of the current is wasted in heating the resisting wire. Let the symbol W stand for the whole electric energy of a current, and let w stand for that part of the energy which the motor takes up as useful work from the circuit.* All the rest of the energy of the current, or $W-w$, will be wasted in useless heating of the resistances.

But, if we want to work our motor under the conditions of greatest economy, it is clear that we must have as little heat-waste as possible; or, in symbols, w must be as nearly as possible equal to W. It can be shown, mathematically, that the ratio between the useful energy thus appropriated, and the total energy spent, is equal to the ratio between the counter-electromotive force of the motor, and the whole electromotive force of the battery that feeds the motor. The proof will be given later. Let us call this whole electromotive force with which the battery feeds the motor E, and let us call the counter-electromotive force e. Then the rule is—

$$w : W = e : E,$$

or, if we express the efficiency as a fraction,

$$\frac{w}{W} = \frac{e}{E}.$$

But we may go one stage further. If the resistances of the circuit are constant, the current c, observed when the motor is running, will be less than C, the current while the motor was standing still. But, from Ohm's law, we know that

$$c = \frac{E - e}{R}.$$

Hence $\frac{C - c}{C} = \frac{e}{E} = \frac{w}{W}$. From which it appears that we can calculate the efficiency at which the motor is working, by observing the ratio between the fall in the strength of the current and the original strength. Now, this mathematical law of efficiency has been known for twenty years,† but has been strangely misapprehended. Another law, discovered by Jacobi, not a law of efficiency at all, but a law of maximum work in a given time, has usually been given instead.

(TO BE CONTINUED.)

THE TELEPHONE CASE.

JUDGMENT.

The Master of the Rolls, in giving judgment on Tuesday in the case of the United Telephone Company *v.* Harrison, Cox-Walker and Co., said: This is an appeal from the decision of Mr. Justice Fry, who found in favour of the plaintiffs with reference to the infringement of a portion of a patent. The portion referred to is the receiver in Bell's patent. Before proceeding further with my judgment, I wish to say that in my opinion the case has been elaborately and remarkably argued on both sides. If I have any complaint at all—which, perhaps, I should not make in a case of this kind, where I have derived so much assistance from the Bar on the subject—it is that, perhaps, the arguments might have been compressed. Subject to that observation, I have only

* This symbol w must be clearly understood to refer to the value of the work taken up by the motor, as measured electrically. The whole of this work will not appear as useful mechanical effect, however, for part will be lost by mechanical friction, and part also in the wasteful production of eddy-currents in the moving parts of the motor. What proportion of w appears as useful mechanical work depends on the efficiency of the motor *per se*, which we are not here considering. In all that follows immediate ly we shall suppose such causes of loss not to exist; or the motor will be considered as a perfect motor.

† See Verdet's "Théorie Mécanique de la Chaleur," where, however, Verdet makes the very mistake so often made, of supposing that the greatest possible efficiency of a motor, working with a given electromotive force, is 50 per cent., or its efficiency when working at the maximum rate.

Digitized by Google

to thank the Bar for the great advantage I have derived from their arguments and from the information afforded. The patent is admittedly one of great merit. It is one of the most important and remarkable inventions of the century, and if it fails in any part it will fail from being made too wide in some of the descriptions, and not being sufficiently distinct. I have said on many occasions, and I say again, when you take out a patent of great and acknowledged merit, it is the duty of the judge, so far as he can consistently with the rules and construction of the specification, to read that patent so as to support and not to defeat it. And that is what I understand of all that has been said about the "benevolence" construction of the statute. The objections raised to the patent are these: —The first objection raised on the part of the appellant was that there was no infringement at all. Now, that depends upon the mode in which you construe the specification. I do not understand that that point was made before the Court below in that wide form, but I consider it to be material. There are two portions which are alleged to have been infringed. One is the permanent magnet, which is called Hickley's, the other the electro-magnet, which is known as the Cox-Walker. As regards the Hickley, I think it is so clear it is not worth discussing; but the suggestion made is this—it was not for an infringement, because the defendants bought it now and again, and were not the persons who sold it regularly, or manufactured it. There was put in evidence before us the defendants' own prospectus, or circular, and it was obvious that they represented to the public they were the manufacturers of the Hickley as well as the Cox-Walker, and they sold it as their own production. I think, therefore, as far as that goes they had no ground whatever for complaint, and the infringement, so far as that is concerned, is plain. As regards the last case—that is, of infringement—that is dependent, no doubt, upon the reading of the specification. I am not going to say, and it is not my opinion, that this is anything but a difficult specification—difficult to construe even now in the light of the further knowledge we possess, and certainly it must have been extremely difficult at the time it was published, and when we knew little about that subject. And, as far as I am concerned, notwithstanding the observations of Mr. Webster, I always felt comfortable as judge of first sittings in knowing there was an appeal from my decisions. I gave them with more confidence when I knew there would be no appeal. This is a case of very great importance, and may be carried further, and if it is carried further I shall be glad of it. Now, what does this specification mean? Does it fairly describe the patent? The description is contained in a very few lines. Before going to that, I may say a word or two about another anticipation. There was an anticipation under Reis's patent. I have looked at it, and I have nothing to add to that judgment. With regard to the invention it is described at p. 18. That has been objected to as going beyond the law. I do not think it does. As I read the variation, it does not appear to me to do more than to say that a plate of thin steel might be used, and I do not see, for myself, that it adds or takes away anything that is material. It seems to me that even if it did, as the law now stands, it does not destroy the effect or strike out the variation. I really think, when you look at it fairly, it does not add anything, and it may be discarded for every substantial purpose from the construction of the patent. Now the first question to consider is what does that mean? It evidently means that the receiver and the transmitter are the same, because it obtains similar motion in a similar steel plate. Then, again, as to the vibrations of the plate in front of the magnet. It shows not only that the plate is in front of the magnet, but that it is attached in front. Then the drawing points this out. It shows that it is attached by two buttons or screws. Now, does it show another mode of attachment? I cannot imagine anybody, having the right, who would not attach it by at least two screws. I have no doubt that any decent workman would have at least put two more. I do not know that it would make much difference. I think he would put two screws at each side at least. I think all that is told us by the specification. It is told us there is this thin plate or disc in front of the magnet, close to the magnet, separate from the magnet, fixed or attached, and in such a way as to keep the whole circumference fixed. That is the thing which is described, and I think sufficiently. The question is, do the defendants infringe? There is no doubt what they used is nipped or capped down by a top screw, similar and for the same purpose. It is only trifling with words to say that is not substantially the same thing as what the plaintiff has described. Therefore, on this question of infringement, my opinion is quite as adverse to the defendants as regards the Cox-Walker as it is with regard to the Hickley. Now we come to a very different and difficult point. Assuming it is an infringement, is the plaintiff's patent bad for want of novelty? Has it been previously published? The singularity of the case is this—if it is a publication, is it a publication of the patentee's own? If a prior invention is not substantiated, it is his. The history of the case is simple. The patentee himself declared I am an inventor, not of the present invention, as it turns out, but a similar invention, and not so perfect—it was in an imperfect or inchoate state. But still he published it to glorify it, and gave the instrument to Sir William Thomson, who was going to the meeting of the British Association at Glasgow for the purpose of publishing it to the world. Now, Sir William Thomson is a great electrician, but I think he was not quite candid with the British Association, because before the meeting he tried to work the machine, and says he could not work it. Something had gone wrong. What it was I will say no more about. He made a speech to the British Association in which he did not tell them he could not work it. He told them, no doubt, what was perfectly true, but at the same time he said he had seen something similar to that he held in his hand at Philadelphia, producing something of articulate sounds, but he did not tell them he had tried to work it himself. He trumpeted forth as a great invention one of those marvellous inventions of a new something which would glorify Mr. Graham Bell to eternity, but he never told them what was the position of matters. When we come to see what had happened this occurred. Somebody or other had told a mechanic who made the instrument for Sir William Thomson to put a screw on the top of the case which contained the magnet, and to screw down the disc. That this had been done purposely is obvious, for the plate juts out from the case, and there is a hole made in it, and a screw put in it. Somehow or other by the shaking of Sir William Thomson's portmanteau, the case containing the magnet got crumpled or creased, and the result was instead of lying flat on the top of the disc, it was slightly raised so as to tilt, and not to touch the case containing the magnet, except at the point where it was fastened with the screw. When it was shown by Sir Wm. Thomson to the British Association, with the suppression of the fact that it would not work, and with a speech which would have led us to expect it would produce marvellous results, everybody could see, who looked at it with attention, that it was tilted. Nobody knew how to work it. The state of knowledge in this country at that time was not so advanced as it is now, and nobody could make anything of it. It was there for several days in the museum or place attached, and nobody could make anything of it—nobody knew how it would work or how it was worked. That leads me to this point—whether the publication shown or not shown was the publication of the "Glasgow," which is something with a top or disc, or something which was permanently and purposely altered. It is impossible to answer that question without you know the minds of the people, and if they had known what is known now, nobody would have understood that the current was strong enough to draw it down. I am satisfied at that time nobody knew those things—they were not acquainted with the mode in which it was worked. Sir William Thomson states he thought at the time that the crease or crumple was done on purpose, and was part of the concern. He does not put it in those words—he speaks of it as not being accidental, and as being produced by a regular cause. The material point to my mind is this: Are you satisfied that there was no ordinary intelligent workman who would have made that thing work? We have this criterion. We have a description in a newspaper, we have a drawing which shows it, and though we have no drawing which shows what it was at first I am satisfied it was different when it was shown at Glasgow. The next question is this: What was the effect of the thing? I agree if you publish an instrument you may publish so as to effect a subsequent patent if your description is as good as that required in the specification, and if you have a new instrument and state its use it is quite sufficient. I will give an illustration to show what I mean. Suppose flutes were unknown, and suppose a man invented this beautiful wind instrument, which, when blown upon, gives out delightful and harmonious sound. It is described as a wind instrument, but if there was nothing to tell what it was, for nobody could use it unless he knew how to move the lips—he must be taught to blow the lips. He would have to be taught whether he is to blow alongside or at the top. The specification is not the less good on that account. It would not be sufficient to say at the date of that specification nobody knew how to blow the flute. Though nobody knew how to make a receiving instrument, yet if we are told this is a telephonic receiver that will give articulate sound, and that to say it is such is a publication of the receiver, it would none the less be a publication because nobody knew how to receive it. There was some form of transmitters at that date that would give articulate sound. I think one ought to hold what took place at Glasgow was a publication of what I will call the Glasgow uncorrected. Is the invention afterwards patented the same receiver, or is it a different receiver, so different as to be capable of being sustained? We must consider what is claimed as the subsidiary part of a great invention to support that claim. In considering the merit of an invention you must consider it as a whole, and you do not require the same amount of merit to support the subsidiary claim to a subsidiary part of an instrument which you do to support the entire invention. If we find that this thing which is the subject matter of this subsidiary case is not the same thing, and that it possesses some advantages —and when I say that I mean real advantages—then it is sufficient. What do we find? In the first place, that there is a difference from the thing shown at Glasgow, whether corrected or uncorrected in several particulars which have been pointed out. In the first place the disc is fastened by a different mode of attachment—in the one case by a screw and in the other by a piece of wood. It appears to me the different mode of fastening or adjustment is material, and the evidence shows that when it was fastened with a screw it got crumpled or creased or out of order, whereas when fastened the other way there was no such probability, and that is an advantage which speaks for itself. I am satisfied from the experiments when you have a very high resistance in the magnet that the mode adopted by the patentee gives better results than the Glasgow machine. I do not say that with a very high power with the Hunning it might not be so, but I do find a distinction with a low power and a greater. I thought one was better than the other. I thought the difference was rather in favour of Bell's instrument over the Glasgow instrument. There is another point. Bell's instrument can certainly be used as transmitter or receiver. As far as I can see, I am unable to dissent from the conclusion of the judge below that it can be so used. If it can be so used, it was the duty of the appellants to show us. There are other points of difference, but they are very slight. The position of the magnet is different. Summing up the whole it appears to me that there is a difference of form, a difference of construction between the receiver patented by Bell and a difference in its use, and, to a certain extent, as between that shown at Glasgow and that which is now described as an invention; and, considering that which you require when you have an invention of great merit and very little to support the subsidiary claim, I think we should not be doing our duty in upsetting this case on such grounds as these. I now come to the last point, which, like all the points in the case, is a serious and difficult one, and that is as to the operation of the disclaimer upon the original claim. Although, perhaps, not very happily drawn, it appears to be fairly confined to the original use claimed, and does not operate to vitiate the patent. The case is one of very great difficulty, and I am not able to say, reviewing the whole of the case, that I am able to arrive at a different conclusion to that which was arrived at by the judge below.

On Wednesday Lords Justices Lindley and Bowen concurred. We hope to give the text of their judgments in our next issue. We may state here, that the evidence given before Mr. Justice Fry in the original case, tried in May last, together with his judgment and illustrations of the various instruments referred to during the case, appeared in Vol. IX. of *The Electrician*, pp. 31, 36, 54, 80, and 115.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of January, 1883, were £1,689, against £2,055 for the corresponding period of last year.

THE BRITISH INSULITE COMPANY (LIMITED).

The second ordinary general meeting of the shareholders of this Company was held at the Guildhall Tavern on the 5th inst., under the presidency of the Right Hon. E. P. Bouverie.

The SECRETARY having read the notice convening the meeting,

The CHAIRMAN in the course of his observations in moving the adoption of the report and accounts said: In accordance with the provision in the Articles of Association, this meeting has been called for the purpose of submitting the state of the accounts and for other ordinary business of of the Company. I shall deem it my duty to occupy your time for a few minutes in explaining what the position of the Company is. In the first place I should say you are aware it has been in existence for only about eight months. The latter part of May was the time when the Company was formed, and since then we have had to set to work at the Board to get the operations of the Company set in motion. The accounts really set forth the position of the Company, but there is an ambiguity in one item in those accounts on the credit side which I shall be glad to explain to you. Perhaps it would be better that I go over the items in the accounts, which will help to make the remarks clearer which I shall have subsequently to make. First of all there is, on the debtor side of the balance-sheet, an item debited to sundry creditors. The moiety of that is for directors' fees, which I should mention have been unpaid. We thought as the Company was inchoate (not at work, at any rate) it was well not to draw the fees. Thus more than half of the item of sundry creditors on the debit side of the balance-sheet represents our fees. On the credit side you see the cash payments and the legal expenses set forth. Then come five items beginning with leasehold property and ending by cash at bankers, all of which are assets of the Company. The leasehold property has been entered in the accounts at cost. We have established our works. I should mention that we were enabled, after some difficulty, to find what I think is a perfectly appropriate site, and that we bought it at a very low figure, with some machinery which was thrown in. The Board has had the leasehold property valued, and, apart from the machinery which was included in the £1,925 that we gave, a very competent surveyor who is not exaggerated in his ideas of the value of property, but who has great knowledge and experience of leasehold property, puts the building and site—the lease alone—as worth at least £2,000, and the machinery which we got thrown in we have had valued to us as being worth about £700. Therefore we had a good bargain there. The plant and machinery have been purchased since. The item does not include the whole of the plant we have been acquiring. The office furniture speaks for itself. The item stock on hand has been misunderstood. It has been supposed to mean manufactured stuff which we could not sell. That impression, however, is wrong. It is materials for manufacture that we have on hand, some of which is very valuable, which we thought well to lay in a good stock of before we commenced, and which I understand, if sold in the market now, would be worth more than we gave for it. That, therefore, is fully equal to cash. The item of cash at bankers speaks for itself. Altogether I make out, without giving the valuation of the leasehold property at a higher rate than we put down, we have assets of over £7,000. Then there is a charge for preliminary expenses, which is always a feature in connection with the establishment of companies, and the liquidation of which with us in our future arrangements will have to be spread over a short series of years. The main part of that—more than half—has been incurred in advertising. Of the last item—administration expenses—half has been actually paid, and I could, if necessary, give you the details of that. I think what I have said, therefore, will enable you to see that we are in most respects ready to begin operations, but unfortunately up to the present period we have not been able actually to commence work. We have got buildings and materials, and we hope to get the machinery. The main part of the profit which is expected to be derived, I may say the whole, from the manufacture of this material, will be got from making it in a large way, and in a cheap and economical manner. The great merit of this patent invention to which we have the right is that it produces a material which is in large request, which is a necessity I may say nowadays of electrical existence, and which can be produced by this process cheaper and better than anything else known in nature. The result will be, if we are right in our anticipation, that there must be a very large demand for a variety of electrical purposes for the stuff we shall be able to produce, and of course the cheaper the way in which we can produce it, the larger the profits of the manufacture. There have been several minor improvements made in the method of manufacture since this material was first invented, and the method of treatment actually hit upon. It has been ascertained that instead of putting the stuff in blocks, and then cutting to the pattern required, it admits on given conditions of being moulded into any shape which admits of moulding. To do this on a large scale and cheaply involves the erection of certain machinery. Our first difficulty was to get a place to carry on our works. There were some peculiar conditions attached to that requisition, one being that it should be in the way and out of the way, where it would be readily accessible, as the materials we have to deal with are for the most part materials of large bulk, and, therefore, that it should be near a railway station or the river, and another that it should not be near any large population, as, in making it, there are some odours which are supposed to be offensive. We know by the experience of the small experimental works established at first in Westminster that there was a complaint of a nuisance on the part of the authorities, and legal steps were threatened. We, therefore, had to provide for this, and after making one or two efforts in another direction by great good fortune, and I think partly through the diligence of our secretary, we succeeded in finding a place which is eminently fitted to all our requirements. It is down at Charlton, within fifty yards of the railway station. It has access to the river and also to the railway, and it is out of the way. There is no population about it. It combines every possible thing we could require for our purposes, and it had the advantage of being very cheap. We have a lease of it for about thirty years—I believe it is thirty-four years—at a moderate rent. Then having got the site (and this took us some time, we did not get the conveyance till September) we had to get the machinery, and it was necessary that the machinery should be adapted to the place. The machinery had to be devised (and that took some time), and it then had to be designed by competent people. Then it had to be given out to be executed. We found that the machinery makers were so full of work that they were very unwilling to have it promised for a certain time, and the result has been practically that we have only been able to get our machinery delivered piecemeal, and the last thing which hung fire was that which we thought we might have got in the first instance, viz., the engine, which was ordered of a maker who was a very large maker, and who promised it in about six or seven weeks; but he has taken over three months to execute the order, and only to-day have we heard of the delivery of the engine. I believe that the difficulty of getting such orders executed is a matter of everyday experience, and if we were to endeavour to get a penal clause inserted in the agreement, the manufacturers would not take the order. As regards this engine, it was the last thing we required, everything else being ready. As to the final completion of the order, our legal advisers had to write a letter to the maker. At last, however, we hear to-day that the engine has been delivered, and I understand now that in the course of two or three weeks we hope to have everything put together, and to set the machinery going, and produce what we have to produce. What we have got to do now is to get orders for our stuff. Of course, in a new invention like this, the expectation that this stuff will be required, and that there will be a large demand for it, is more or less a speculation—that is to say, it is in the womb of the future to decide whether our expectations that there will be a great demand for it will be realised or not. I can only say as to that, that I judge to a certain extent on general principles, and partly endeavour to form my own opinion as to the state of the case. When you have a monopoly of something that people do not care much about, or which is a matter of fashion, it is quite possible that the demand may cease or the fashion change; then you may be left with no real demand for that which you produce. But when you produce what I may call a necessity of existence of any kind, and have a practical monopoly of it, and are able to produce it better and cheaper than any one else, then those requiring it must come to you, and there is a fair chance of making a very large profit. That is exactly the general principle in relation to which we stand. We believe we have by our patent the right of making something which electricians for a variety of purposes must have. For batteries, for the minor appliances of telephony, of electricity, and for insulators of all kinds, insulating material is absolutely necessary. One of the commonest things with which we are all familiar is a thing which we see on the telegraph posts all over the country. This is made of porcelain. We believe that by our stuff it can be made better and cheaper than by porcelain, and that it will replace the present porcelain article. We know that we supplied an order to the Post Office some time ago, and they have been sufficiently satisfied with it to ask us quite recently to make a tender to execute another order. Besides that there are almost an infinite number of things to which insulation is a requisite in electricity. We know thoroughly well how the development of the application of electricity to ordinary affairs is going on now, and we think we have got something which is a necessary ingredient in that application. If that is true, and I believe it is, we have got hold of a very good thing, and if the crop is properly nurtured, and the production is carried out in an economical and successful way, we ought to have got hold of a very successful business. It is however, to be tested by experience. As yet we have done little except lay the foundation, but now that we have got our requirements we hope to produce our stuff. I am a great believer in the thing myself. I have got a considerable stake in it. Though I belonged to the original parent Insulite Company, I have put not only what came to me from that, but a great deal more into this, and in reasonable time I feel satisfied that it ought to be a very fine property. An unavoidable delay has occurred in getting to work, but that fact is not a deteriorating or damaging one, and I hope the proprietors will so regard it. I believe I am expressing the opinion of the Board—certainly my own—when I say that there is no reason, so far as I am aware, to think that we have been injured by the delay. On the contrary, everything that we have done since, every step that we have made since (for steps are being continually made in the way of discovery about electricity), every step has convinced me of the value of this invention. We have Dr. Fleming, the inventor, a gentleman of the first scientific attainments, of high Cambridge distinction, of great knowledge and ability, here in this room, and he has perfect confidence in the invention. Whatever he may have got out of the sale of this patent, he is such a believer in the thing itself that he has put it into the Company, and Dr. Fleming will show you presently two or three methods by which this material can be turned to practical account, and in a way that no other material can practically be used, and I hope he will help to demonstrate the value of your property. Sir George Rickards reminds me that Sir William Thomson, a great authority in this matter, has written in the strongest terms of praise of this material. What Sir William has written has been sent round to the shareholders, and there is no reason to doubt the correctness of his views, which are thoroughly in confirmation of the views which we entertain ourselves. I now move "that the report and accounts be received and adopted," and I will ask Dr. Fleming to say a few words about this matter.

Dr. FLEMING, in the course of a very interesting address, said:—In response to your invitation, and with the consent of this meeting, I will offer a few remarks and give you a little information which I think I am probably better fitted to do than any one in this room on the probable commercial future of this material of which I am the inventor. I am perfectly aware of the proverbial sanguineness of inventors, but I also rise with a sense of responsibility to keep within the strictest limits of moderation in my remarks. I am the largest shareholder in this Company, and, as the chairman has said, not only that which we may have taken out of the original concern we have put back into the Company, but even more. I will now detain you for one or two moments in explaining to you how we expect to do a large business by the manufacture of certain articles with this material. I have here a series of samples of materials and articles we are

Digitized by Google

making. We have not altogether been idle in the interval between our formation and the present moment. We have occupied ourselves with preparing a series of articles which we expect to supply in very large quantities. You have before you, first, Sir William Thomson's report on this material, to the effect that it is of exceptional value. You know also that it is formed of cheap and abundant raw material, and that the process of manufacture consists in pressing these materials into moulds, and manufacturing therefom any of these articles. Here is a Post Office insulator from a pattern supplied to the English Government, and they have had a very large number of these insulators. In addition to that, a considerable number have been supplied to the Duke of Sutherland for his telephone lines around Dunrobin Castle, and the experts who put them up speak highly of these telephone lines. We have an article here to be supplied at a price which can compete with stone, over which it has three advantages. It is not nearly so fragile, it is also very much lighter specifically, and every telegraph engineer knows the importance of getting an insulator, as light as possible. The third advantage it possesses is that it has a very much higher electrical insulating power than stone or porcelain. I am perfectly convinced, as soon as we can produce this insulite in sufficient quantities, that we shall have a very large business in that single article alone. Here is an ordinary battery cell made in thousands every day for telephonic and telegraphic purposes and for medical batteries. What are the objections to it? It is made of glass, and is very fragile. The Telephone Company break 25 per cent. of those they send out. Then they cannot seal a glass cell so as to make it perfectly liquid-tight. With our material we can make the cell very much lighter, very much stronger, and it has the great advantage that you can solder this insulite together. This battery, too, unlike one of glass, can be charged and sent out ready for use. You do not require to leave its charging to those to whom it is sent. This one is charged now. It is very strong. But if it is necessary to give these batteries a little additional strength, you can put them in a light tin case, which can be sent by parcels post ready charged. If you ask what it is that limits the use of electrical alarms, you find the reason is because people cannot be troubled with the difficulty of charging batteries. If you are living near a large town, that can be done with comparative ease, but not otherwise. We can make our batteries, too, in sets of one or two. These batteries (indicating several on the table) have been charged for a long time, and they can be thrown about, and they are perfectly uninjured by any ordinary usage. A battery cell like this can be made up with a bell, and so you can yourselves put up your electrical bell or burglar alarm at the window. Having given practical illustrations of this, he proceeded: I think in this business we have the monopoly. This cannot be done with glass. We have made up a large number of insulators of various descriptions. There are some telephone insulators. Here is an insulator which is being used to insulate the electrical railway which is to be laid down at Portrush by Siemens Brothers. I think that they will find when they come to use it that this is just what they want. They could not use ebonite on account of the price, or stoneware, or glass, as both would be too fragile. In this article alone I think we ought to look to getting a good business. But, passing on from batteries and insulators, there is another point of great importance which this Company has the power to do. Speaking as one who has something to do with electrical engineering, I can say there is a large demand for electric lighting which cannot be met up to the present. There is not one person in a thousand who would care for the trouble and expense of having a steam engine, boiler, and dynamos on their premises to produce electric light, and if they had it it requires constant vigilance on the part of some one to manage it, or the light would be going out. Now, even if they look to accumulators to do this, accumulators require to be charged by a dynamo machine, and to be carried backward and forward for that purpose. There is a battery lying on this table, and they can be made large as easily as they can be made small. It is only a question of the mould. We can make them of true shape, with certain grooves in the side, and then with putting in certain plates and chemicals, it is possible to make an installation of the electric light. This Company can supply that demand at once for the incandescent light. Having given a practical illustration of this, Dr. Fleming continued: We can, therefore, give people the privilege of having the incandescent light in their dining or drawing rooms by having a few insulated boxes, with the proper plates. Here must be a very large field of operations, and the moment we are in a position to supply this in large quantities, we shall be able to do an immense business in this article alone. The first twenty years of this century were occupied with the development of the steam engine for human purposes. The last twenty years of this century will certainly be marked by the industrial development of electricity. For that purpose a cheap and easily managed insulating material will be absolutely essential, and as soon as we have organised our factory and are prepared to turn this out in large quantities (and that is a matter I am giving personal attention to) I do not see how we can fail shortly to be doing a sound, progressive, and remunerative business.

In reply to a question, Dr. Fleming added that the cost of the electric light apparatus he had shown would depend on the number turned out. The larger the output the cheaper they could make them.

The Chairman, in reply to questions, thought that the property they had acquired at Charlton was in as isolated a place near a railway station as could be found. The fumes given off in the manufacture of the material were not unwholesome, and personally he did not think the smell disagreeable. He was told by the engineers that they ought to begin to make the stuff in about a fortnight or three weeks. He did not like to make a positive statement about the matter. He rather hoped that a call would be avoided for the present. He feared that his remark as to their business being speculative had been misunderstood. He considered anything speculative as to which there was a total want of experience, and the demand in connection with a new article must be a matter of the future. As to why the machinery had not been ordered before, they had first to get a place to put it in, and the apparatus, to a certain extent, had to be adapted to the place. The engine might have been adapted to any place, but as far as he had any opinion about the matter the engine was the thing about the acquisition of which it was probable there would have been the least difficulty. They had, however, as he had already intimated, had unexpected difficulty in obtaining one. At the request of the Post Office they had sent in a tender for certain work. He could not say that they had at present any large orders for battery cells. They could not apply for orders until they were ready to execute them. The insulators already supplied to the Post Office were paid for.

A Shareholder inquired why in that case there was no profit and loss account. He also saw that the item of "preliminary expenses" stood in the balance-sheet as an asset.

Mr. Price (of the firm of Price, Waterhouse, and Co., auditors of the Company), replied that no operations had yet been begun by the Company which could call for the production of a profit and loss account. The cost of the execution of the trial orders which had been received (and he might remind them that a trial order was given with the view to giving a larger order should satisfaction be afforded), and the money received from those trial orders had been dealt with in the current expenses. No accountant could prepare a profit and loss account of any company in such a case as this. The preliminary expenses, too, had not been put down as an asset, but as a means of showing how the money had been expended. Those expenses would have to be liquidated from profits in future years.

Mr. E. Harrison stated that, although he had been interested in what he had seen and heard at the meeting, the Company had been carried on in an unsatisfactory manner. They had been established nine months, and nothing had been done. There was no computation as to what they could turn out, or what the cost or the profit would be. Indeed, everything, in his opinion, was vague. He supposed, too, that the shareholders had seen the circular which had been issued by Mr. Arnold White, and he asked that gentleman whether he was going to take any action on it.

Mr. White replied that he should take his own course.

Mr. Harrison (continuing) again contended that there was a great dearth of information.

The Chairman, in reply, asked how was it possible to suppose that the manufacture of the material on a large scale was to be prosecuted, and all the necessary apparatus and plant got ready for the purpose at once. The prospectus itself stated:—"It is intended that a factory on a scale sufficient to meet the probable demand shall be at once erected." What they had to do could not be done all at once. Any one, with experience of public works must know that a considerable time was necessarily consumed in getting the requisite machinery and the whole of the plant set to work. He could not say how many tons a week could be turned out; but they had a very large quantity of the more costly material—something like £4,000 worth—and they hoped that there would be a large demand, and that they would meet it.

A Shareholder inquired whether it was not a fact that up to that moment, or nearly so, quite apart from the machinery, it had not been known to the Company how to prepare the material economically.

The Chairman: Oh dear no. It was known perfectly well at the time the patents were taken out, and the Company formed. There have been some improvement since, and Dr. Fleming is always making improvements.

Mr. Porter said that he knew nothing of the affairs of the Company except what he had learnt from the various circulars which had been sent to him, but it appeared to him that the Chairman had by anticipation answered the question just put. The Chairman had referred to the fact that they could now mould the material at once, whereas formerly it had to be made into blocks and cut as required. He thought it must be patent to all that that was a most material improvement, and must tend considerably to cheapen the process of manufacture. He thought that the information in that respect alone was very important, and gave them every reason not to regret the delay which had taken place. Again, every one with experience of machinery or new apparatus knew that delay was unavoidable. He knew nothing of the reason for the delay till he attended that meeting, but he thought that the explanations of the chairman had been decidedly satisfactory, and that the shareholders had every reason to think more of the process than they did when the Company was first established.

The Chairman, in reply to another question, quoted the clause in the Articles of Association of the Company relative to the amount of the directors' fees, which he reminded them again had not been taken. He had every reason to hope that for the present a call would be avoided—until they saw their way to large profits, and if a call were then made for an extension of the business he hoped it would not be regretted. Another point of importance as to the machinery was that it was so contrived as to save labour, and he believed that the greater part of the operations would be performed by unskilled labour, by women and children. Replying to other questions, he added that as regarded obtaining the largest portion of the material they required, sawdust, there would be no difficulty; and as regarded the other portion, he believed there would be no difficulty. It was a special material, but there were two or three substitutes for it. The Articles of Association provided only for annual meetings, but the directors and the shareholders had the power of calling other meetings. He thought they must be a little guided as to the circumstances, but, as far as he was concerned, he should be disposed to their having half-yearly meetings. He then put the resolution, and it was carried unanimously.

On the motion of Mr. J. Dummett, seconded by Mr. Edward Easton, the retiring directors, the Hon. E. P. Bouverie, Mr. M. M. Moore, and Dr. J. A. Fleming were re-elected to their seats at the Board.

A Shareholder then moved the re-appointment of Messrs. Price, Waterhouse, and Co. as auditors of the Company for the ensuing year.

A Shareholder, in seconding the motion, stated that a few days ago he met Professor Stuart, of Cambridge, who not knowing that he (the speaker) was at all interested in the Company, after speaking of Dr. Fleming in the highest terms, alluded incidentally to a remarkable invention of that gentleman of a substance called insulite, which he (Professor Stuart) thought of very great value, and for which he believed there would be a very great demand.

The Chairman put the motion, and having declared it carried, and announced that that closed the business, said he thought he might undertake on the part of the directors, that when they had made some little way, as they hoped to do, they would send round to the shareholders a circular as to the prospects of the business.

On the motion of Mr. Porter, a vote of thanks was passed to the chairman, and

The Chairman having expressed his acknowledgments, the proceedings terminated.

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION (LIMITED).

The adjourned meeting of the above Corporation was held at the City Terminus Hotel on the 5th inst., under the presidency of Sir H. W. Tyler, M.P.

The CHAIRMAN opened the proceedings by reading the report of the scrutineers on the poll demanded at the meeting on the 23rd ult., and taken on the 30th ult., on the amendment proposed by Mr. Gillitt, seconded by Mr. Allsopp, as follows: "That a committee of shareholders be appointed to consider and report upon the affairs, position, and general conduct of the Corporation." The shareholders claimed to vote in respect of 27,758 shares attending the adjourned meeting by proxy or in person. Votes in respect of 5,760 of such shares had been on investigation disallowed by the scrutineers, and he was told that of the shares disallowed about two-thirds were in favour of the directors and one-third in favour of the amendment.

Mr. GILLITT thought that was hardly so.

The CHAIRMAN: There were more in favour of the directors.

Mr. GILLITT assented.

The CHAIRMAN: In the result 22,088 votes were allowed by the scrutineers, of which 8,750 were in favour of the amendment and 13,338 were against the amendment, showing a majority against the amendment of 4,588 votes. This was signed by Cecil Coward, Alfred Gillitt, J. S. Sellon, and F. G. Stuart. He therefore declared the amendment lost. Continuing, he put the original resolution for the adoption of the directors' report and balance-sheet. On putting it to the contrary, there were several dissentients, on which

Mr. GILLITT stated that the objection was a mere matter of form on their part to show that their opinion had not altered. They were willing that the Chairman should announce that the resolution was carried.

The CHAIRMAN said that he must take the votes of the meeting, and having done so (without announcing the numbers) he declared the resolution carried. Continuing, he moved the confirmation of the appointment as a director of Lord Claud J. Hamilton, M.P. They were, he said, very sorry indeed at the beginning of last year to lose the services of one of their most valuable directors, Mr. Nettlefold. Mr. Nettlefold was a gentleman who had shown very great interest in the concern, but in consequence of a family affliction, and having the whole of a very large business left on his hands, he was obliged to resign his seat at the Board. They were therefore obliged to fill the vacancy, which they did by appointing Lord Claud J. Hamilton. The position and character, as well as the business capacity of Lord Claud, would be of the greatest use to the Company.

The VICE-CHAIRMAN (Mr. J. S. Sellon) seconded the motion, and stated that throughout the time Lord Claud J. Hamilton had held a seat at the Board he had been a most independent member of it.

The CHAIRMAN put the motion and declared it carried unanimously. He then moved the re-election as directors of Messrs. Sellon, Ladd, and Courtney. He observed that Mr. Sellon was very much interested in electric lighting, independently of any particular company. He was a most indefatigable worker, as, in fact, were all the directors, on behalf of the interests of the Company. There was hardly a Board meeting held at which they did not sit for six hours, in addition to having intermediate meetings. With regard to Mr. Ladd, that gentleman was one of the earliest labourers in the field of electric-dynamo machine work, and actually produced the first dynamo machine that was worked. Mr. Courteney, who was a barrister of high standing, was unfortunately absent in America.

Mr. HERBERT GIBBS seconded the motion, which

The CHAIRMAN put and declared carried.

Mr. NETTLEFOLD next moved the appointment of Mr. A. E. Jarvis as auditor for the ensuing year, observing that that gentleman had been auditor since the formation of the Company, and thoroughly knew the system of accounts.

Mr. BEDFORD seconded the motion.

The CHAIRMAN put it, and it was carried unanimously. Continuing, he said: I have only now one other resolution to propose—that is on a matter of special business—"That the directors be authorised to apply for an official quotation on the Stock Exchange in respect of 700 fully paid-up shares, numbered 40,001 to 40,700, inclusive, in the Corporation, issued to Mr. C. F. Brush, or his nominees." These shares were issued on the responsibility of the directors, and as it was entirely within their power to make the issue, we do not ask the shareholders to authorise the issue on this occasion. But it has been remarked to us by the brokers of the Company that to get an official quotation on the Stock Exchange of these shares, and to place them in the same category as the other shares, it was desirable to get the authority of the meeting to apply for an official quotation on the Stock Exchange. These shares were issued in May, 1882, as a matter of bargain with Mr. Montgomery, who was here at the time in regard to the Russian patent, the issue of which has been delayed for a very long period. We made in the matter what we believe a very good bargain in the interests of the shareholders.

The VICE-CHAIRMAN, in seconding the motion, said that there was not one of the shareholders who, if he knew the whole of the facts surrounding the issue referred to, would not approve its having been made. It was a most beneficial transaction for the Company.

The CHAIRMAN put the motion for approving the resolution.

Mr. LANE-FOX: May I ask a question?

The CHAIRMAN put the motion to the contrary, and declared it carried unanimously.

Mr. LANE-FOX wished to know if he might ask a question with regard to the issue of these shares.

The CHAIRMAN: It is too late: the resolution is carried.

A VOICE: It was not put.

Mr. GILLITT thought it was hardly worth while to have referred to the number of votes disallowed; but as they had been referred to by the chairman, perhaps he ought just say that, as nearly as he noted them down in going through the scrutiny, there were 2,100 and a few over struck off the votes given in favour of the amendment. That would leave about 3,600 struck off as against it. He thought that they would all feel satisfied that so large a number of votes were recorded out of the total, nearly 28,000 votes were recorded out of 40,700. That was quite as large a proportion as one would expect to find in any company, and as such it was a satisfactory expression of opinion of the body of the shareholders.

The CHAIRMAN observed that they were quite prepared to admit that the proportion Mr. Gillitt had indicated was correct. He formally announced that that closed the business.

Mr. NETTLEFOLD thought that they could not separate without passing a vote of thanks to the chairman for presiding ("No, no," and hear, hear). Coupled with that, he thought they ought to give their best thanks to the directors, who bestowed so much time, labour, and attention on the affairs of the Company. Gentlemen who had not been on the Board knew very little of the amount of trouble and attention that were given to the affairs of the Company by the directors. They sat at the Board every week from four to ten o'clock at night. Besides that they had constant committees; and, indeed, they would all understand the amount of work that was required from a board which had to promote an entirely new industry. Therefore, he contended their thanks were due to Sir Henry Tyler for presiding over the meeting, and also to the directors for their attention throughout their term of office.

Mr. ASH seconded the motion, which was carried.

Mr. BULLIVANT: I should just like to say a few words as a director, appointed by you two years ago, with others, to manage the Company, and I think, in justice to you, we should say what we have done, and how we have worked your Company since we started. You trusted us as directors with £238,000 of called-up capital to work this Company to the best advantage for you. With that we had to buy the Brush patent for pretty nearly all the world except America. We completed that, as instructed by you. We then found we had not quite a complete system of electric lighting, and we therefore thought it advisable to secure the incandescent lamp patent of Mr. Lane-Fox, which we did, our arrangement being that we should pay him £5,000 in shares of this Company, that he should participate in half of the money derived from the sale of foreign patents, and that he should also receive 25 per cent. of all the profits made upon the working of the incandescent business. Having done that, we thought, having completed our system, that we ought to make known our system of lighting throughout the world as far as we could. To do this we exhibited, as you know, at the Paris Exhibition. You must remember at that time electric lighting was not so well known as it is now, and we were anxious to show that the system we had was the best that was known, as certainly it is the best now known. We therefore went to considerable expense, and at the Paris Exhibition we exhibited sixty arc lights, running over a circuit which no other system could do, and with our machinery we lighted up there about 1,000 incandescent lamps. I think those who saw it will say that the way we exhibited these did credit to this Company. Then we were left to carry out this business, and we were left with the English patent. The question was, how should we work it? We knew that the capital we had then issued (£400,000) was quite an insignificant sum to work so large a district, and we therefore had to manage the best way we could, and we considered that we had better divide England and Scotland into different sections, and to sell concessions for those various districts. The result has been this, that there have been companies formed now, with good boards of directors, to work our system throughout England and Scotland, with an issued capital of above £1,500,000, and with an unissued capital, but authorised to be issued, of another £1,500,000. We thus stand, so far as England and Scotland are concerned, as a manufacturing company. We then began to look about and fit up works—we had started before—we fitted up the Portpool-lane works and also the Victoria works, and we found our business then was so great that we were obliged to take other works. We have now fitted up those works with the most improved modern machinery, and to enable us to supply apparatus for electric lighting on the very lowest scale. What have we done besides? We have returned you £275,000, and remember the paid-up capital is £238,000. Now, can you point to any other electric lighting company, or any other company at all, that has done anything like so well for their shareholders as we have done? Can you name any company ever formed that has established a business as has been established now to work your patent throughout England and Scotland; and whatever business is done (and no doubt it will be enormous) must bring profit to you. That electric lighting has for a time met with a check there can be no doubt, but it is very easily accounted for. Besides having many opponents as regards gas and so on, the Electric Lighting Act has for a time stopped work. At the present time it is not decided who shall give the light in the different districts—whether it shall be the local boards, or, if not these, whether it shall be done by a company, and, if so, what company. Till these questions are settled there is a check on electric lighting. But, as to the future of electric lighting, I do not suppose there is one in this room questions for one moment that the electric light is to be the light of the future, and, if so, is there any other company at the present time in anything like our position? Has any company anything like our system, or so good a system as we have? Then why have we been met here with a feeling of dissatisfaction among our shareholders? Had we had our original shareholders here they would have looked on us in a very different manner to what the present shareholders do. If we had the original shareholders instead of those who have been buying the shares at enormous prices there would have been no dissatisfaction with what the Board have done. Remember that we, as directors, have had nothing to do with the price of your shares. We have had nothing to do with that. All that we have to do, and are determined to do, is the best we can for the shareholders who have entrusted us with their capital, and I think I may say without question that no company has ever been formed that has worked better for their shareholders than we have for you. We work up to ten at night for your interests, and have done it with an amount of pleasure, as we felt our shareholders would be satisfied with us. Now we find we have a great many dissatisfied shareholders. For my own part I should have been delighted to work for satisfied shareholders, but I am determined not to work for dissatisfied shareholders. I shall, therefore, only remain on your Board until another director is found to take my place, and as soon as a gentleman can be appointed to my place I shall resign. I shall not work for shareholders who have shown such dissatisfaction. I think it is right that you should know what we have done since we were appointed, and I think it is also just to ourselves that we should state our position.

The CHAIRMAN: It only remains for me to return you thanks on behalf

Digitized by Google

of myself and the Board for your expression of thanks, and to say that having got over our little difficulties for the moment our best services are now entirely at your disposal. We have had a check to our business, and a severe one for the moment, but we still believe in this business, and shall lose no opportunity of advancing your interests by any amount of energy we can bestow on the affairs of the Corporation.

THE TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on the 6th inst. at the offices, 38, Old Broad-street, Sir Daniel Gooch, Bart., M.P., in the chair, for the purpose of passing a special resolution approving a Bill now pending in Parliament, intituled "A Bill for removing doubts as to and for extending the powers of the Telegraph Construction and Maintenance Company, and for other purposes."

Mr. W. SHUTER (the manager) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, we have called you together to-day for the purpose of asking your authority to a Bill which we have brought into Parliament this Session for the purpose of extending the powers contained in our Memorandum of Association. The powers now as mentioned there are "for the construction, laying down, and maintenance and working of submarine or land telegraphs and apparatus, the importation, manufacture, and sale of all materials, articles, and things in any way used in or connected with the construction, maintenance, and working of telegraphs." You will see from that at present our powers are limited very much to telegraphs alone, but since the formation of this Company you all know the use for electricity both for lighting and for other purposes has very much developed, and with the means at our disposal we think it is to your interest we should try to avail ourselves of what we possess in the shape of machinery and appliances to get some of the business connected with those other branches of electric departments. The Bill, which is a very short one, shall be read to you if you wish it. I need not read all the clauses of the Bill, because they merely set forth the position of the Company, but the clause which affects you is this. (The clause, here read by the chairman, referred to the power which it was proposed to confer on the Company in regard to electric lighting.) The necessity of the Bill arose from the fact that you cannot alter your Memorandum of Association by the act of the shareholders. To enable you to do that it would be necessary to wind up the Company and establish a new company under new Articles of Association, and, therefore, we go to Parliament as the only other alternative for the purpose of enabling us to accomplish that object. I do not know that I need say more to you now, and I therefore move—"That the Bill now pending in Parliament, intituled a Bill for removing doubts as to and for extending the powers of the Telegraph Construction and Maintenance Company (Limited), and for other purposes be, and the same is hereby approved, subject to such additions, alterations, and variations, if any, as Parliament may think fit to make therein."

Sir GEORGE ELLIOT, Bart., M.P.: I have much pleasure in seconding that.

The resolution was put, and carried unanimously.

The CHAIRMAN said that, of course, the resolution would have to be confirmed, and that it would be done at the next general meeting.

Mr. W. ABBOTT: Well, sir, before separating, allow me to say a few words. The resolution was carried, I have no objection to it, I am sure the proprietors present are not likely to have any objection to it, because it is carrying out a principle which I took upon myself to suggest at a previous meeting, that this company, with its great reputation, its large capital, and its extensive staff of gentlemen well versed in the knowledge of electricity should identify itself more with electric lighting, and other appliances connected with electricity. I am, therefore, very pleased indeed, sir, that you have carried out this suggestion which I made some year and a half ago. It may appear somewhat late in the day [hear, hear]. A gentleman says "hear, hear," but I am the first to come before you "with the candle and white sheet," and renounce my former opinion that you should have proceeded precipitately in carrying out the principle of electricity. When I was down at the Crystal Palace, several times I saw Sir Daniel Gooch moving about the electrical departments, and I thought that something would be up very likely, and that the Telegraph Construction and Maintenance Company were about to identify themselves with the electric light, but I know your characteristic caution. You have proceeded with caution, and therefore you are much more likely to be successful, as you have the experience now which other companies have given you, and you are very much more likely to make this new enterprise profitable. I think it is only right, as I had suggested it, I should say I commend you for the caution you have shown, and I have no doubt it will result in considerably more profit than if you had gone into the vortex of speculation through which so many companies have suffered during the past year [cheers].

The CHAIRMAN: If no other gentleman has anything to say, that concludes the business of the meeting.

Mr. W. ABBOTT: I beg to propose a hearty vote of thanks to Sir Daniel Gooch and the other directors for what they have done for us up to the present time.

The resolution was seconded and carried.

The CHAIRMAN: Gentlemen, we are very much obliged to you for your confidence, and shall do our best to merit it.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending February 2nd, 1883, were £2,638, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY (LIMITED).

Directors' report for the year ending December 31, 1882, to be presented at the nineteenth ordinary general meeting of the shareholders, to be held at the City Terminus Hotel, Cannon-street, London, on Tuesday, the 13th February, 1883, at 12 o'clock noon. The directors have much pleasure in stating that every department of the Company's business has been well employed during the past year. On reference to the annexed accounts a large reduction will be observed in the item debentures and shares in other companies. The year's sales of these securities have realised a considerable profit. The net profit amounts to £192,784 9s. 6d. Adding £21,526 17s. 9d. brought forward from 1881 and deducting £15,600 interim dividend paid in July, there remains a disposable balance of £198,711 7s. 3d. The directors have added £100,000 of this balance to the reserve fund, raising it to £200,000, and they now recommend the distribution of a dividend of one pound per share and a bonus of £1 per share, amounting together to £62,400, and making, with the interim dividend, a total payment for the year of 25 per cent., free of income-tax, carrying forward £36,311 7s. 3d. To enable the company to meet the demands of an increasing business, considerable sums have been and are being expended on the construction of buildings and machinery at Silvertown and at Persan-Beaumont, and additional land has been acquired for the necessary extension of the Persan factory, and for obtaining access to the railway. For these purposes, and to provide further working capital, the directors have deemed it necessary to make the addition to the reserve fund stated above. In the cable department contracts have been carried out for the French and Canadian Governments, and for the Central and South American, Mexican, Direct Spanish, West India and Panama, and Western and Brazilian Telegraph Companies. The cables which the company contracted to lay have been successfully completed under the able management of the Company's engineer, Mr. Robert Kaye Gray; and he and the entire staff are entitled to the highest commendation. The directors have for some time felt it to be very desirable that accommodation should be provided for the comfort, instruction, and amusement of the workpeople at Silvertown. They will, therefore, submit a resolution at the coming meeting authorising the expenditure of a sum of £6,000 for the erection of a hall and dining rooms on the Company's property. Further details will be given at the meeting.

SLIP

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended February 9 were £3,876.

ANGLO-AMERICAN BRUSH CORPORATION.—Sir Henry W. Tyler, M.P., has resigned the office of chairman of this company.

ELECTRIC LIGHT FOR LOS ANGELES, CALIFORNIA.—The city council of Los Angeles have resolved to adopt the electric light for their streets.

ELECTRIC LIGHTING IN THEATRES.—It is stated that the Théatre du Parc in Brussels will be wholly lighted by means of incandescent lamps at the end of the present month.

NEW BOOK.—We have received a copy of the second volume of Senor Antonio S. Saavedra's "Estudio de la Electricidad del Magnetismo y del Electro-magnetismo," Second Edition.

ELECTRIC LIGHTING IN BRUNN, AUSTRIA.—The Edison Company are installing 250 lamps in a woollen factory at Brünn. The work is being done under the superintendence of Mr. Francis Jehl.

ABANDONMENT OF A PROVISIONAL ORDER.—The Pilsen, Joel, and General Electric Lighting Company have withdrawn their application for a provisional order, deposited with the Board of Trade under the Electric Lighting Act, with regard to the City.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending February 9, 1883, were £2,542, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

NEW COMPANIES.—The Electric Supply Company, of San Francisco, has filed articles of incorporation with a capital of 60,000dols. Articles of Association of the New York and Brooklyn Electric Light Company have also been filed; capital, 25,000dols.

LONDON PLATINO BRAZILIAN TELEGRAPH COMPANY.—The revenue of this company for the month of November, 1882, is estimated at £1,936 (Western Brazilian portion £1,433, land lines £503), as against £1,796 for the corresponding period of 1881.

ELECTRIC LIGHTING IN RUSSIA.—The agent of the Edison Company in Russia, Mr. E. Fedor, has recently fitted up machines and lamps in the following towns, viz., Tammerfors, Helsingfors, 60 lamps in a tapestry factory, and Lorefow, 240 B lamps in a sugar factory.

PROPOSED EXHIBITION AT HUDDERSFIELD.—The Huddersfield Technical School and Mechanics' Institute are going to hold a Fine Art and Industrial Exhibition in June next. Motive power will be provided free of expense. Applications for space must be sent before 21st inst., to Mr. A. Keen, secretary, Huddersfield.

ELECTRIC LIGHTING AT HAMPSTEAD.—The Vestry of Hampstead have been considering the provisional orders which concern their parish. They do not seem to be very favourable to the Metropolitan Brush Company, one of the applicants for an order, but look more favourably on Messrs. Ferranti, Thomson, and Ince.

THE PILSEN LAMP.—We understand that the Science and Art Department of South Kensington have just given an order to the Pilsen, Joel, and General Electric Light Company for twelve Pilsen arc lamps, and the necessary dynamo machines. This order has been given after a careful trial of the working of a Pilsen lamp.

PUMPING WITH DYNAMOS.—The Electric Carbon, Storage, and Apparatus Manufacturing Company, of Leith, inform us that they have just concluded arrangements to do the pumping at the Marquis of Lothian's collieries at Dalkeith by electricity with one of Dr. Higgs's dynamos on the surface, and Dr. Higgs's improved motor below ground.

EXHIBITION OF METEOROLOGICAL INSTRUMENTS.—The Council of the Meteorological Society have determined upon holding at the Institution of Civil Engineers, 25, Great George-street, S.W., on the evening of March 25 next, an exhibition of meteorological instruments which have been designed for, or used by, travellers and explorers.

ELECTRIC LIGHTING IN BELFAST.—The premises of Messrs. Keys Brothers and Sims, of Donegal-street, Belfast, have for the last month been lit up by four Pilsen arc lamps, one outside and the rest inside the building. The lights have been put up by Messrs Woodhouse and Rawson, and have given every satisfaction, people being much surprised at their steady working.

TASMANIAN TELEGRAPHS.—From some statistics of the progress of the colony of Tasmania between the years 1871 and 1880, published by the Government statistician, it appears that telegraph stations show an increase of 349 per cent., miles of wire 299 per cent., numbers of messages 429, and amount received 555 per cent., the increase in expenditure being only 215 per cent.

ELECTRIC LIGHTING IN BRUSSELS.—The House of Parliament in Brussels has been partly lighted for the last few days by means of Edison's system. One hundred lamps are distributed throughout the hall of assembly. The engine used to drive the dynamo is one of Messrs. Robey's of Lincoln. The installation was carried out by the Compagnie Générale d'Electricité, under the superintendence of M. Nothomb.

AYRTON AND PERRY'S EXPERIMENTS WITH PLATINUM AND MAGNESIUM.—Writing on the subject of Professors Ayrton and Perry's experiments with platinum and magnesium strips dipping into mercury, whereby they obtained a current, M. B. J. Goossens shows in the *Annales Phys. Chem.* that the current thus obtained is caused by the evolution of heat in the formation of the magnesium amalgam, and is, therefore, a thermo-current.

GAS IN PARIS AND LONDON.—In a recent lecture delivered by M. H. Aerts, manager of the Brussels Municipal Gas Works, the following comparison between Paris and London gas was instituted:—"The Paris burner consumes 105 litres, or nearly 4 cubic feet per hour. The London burner consumes 142 litres, or nearly 5 cubic feet per hour. The illuminating power required in London is 16 candles for 142 litres (5 cubic feet) of gas. The normal illuminating power of Paris gas, consumed in London burners, corresponds to 15·2 candles."

ELECTRIC RAILWAYS.—Electric power as a means of traction on railways seems to be gaining ground every day. We have instances at Berlin, some mines in Germany, Portrush (Ireland), and elsewhere. Electric railways are talked of in Switzerland and Vienna, and now we hear that the Chicago Town Council has been memoralised by a Mr. Hannahs on the subject. Mr. Hannahs wants to erect an elevated rail-

Digitized by Google

way in Chicago, the motive power on which shall be supplied by electricity, whilst the carriages will be lighted by the same agency.

Electric Lighting for War Vessels.—The French Government have, it is stated, determined on supplying a number of their men-of-war with Gramme machines and lamps, the latter provided with Mangin reflectors. Steam launches belonging to men-of-war are to be furnished with powerful arc lamps. Already several ships have been fitted up internally with incandescent lamps. Amongst these we may mention the Redoutable. Gramme machines, driven by Brotherhood engines, supply the current to the lamps, which in this case are Swan's. It is probable that the Océan, another ironclad, will be lighted by means of Edison lamps.

"Journal of the Society of Telegraph Engineers."—We have received a copy of the January number of this journal. Amongst other things, it contains Mr. Preece's paper on "The Munich Electrical Exhibition, 1882;" Colonel Webber's paper, entitled "Notes on the Telegraphs used during the Operations of the Expeditionary Force in Egypt." Of original communications there are three, viz., one from Mr. Preece on "Recent Progress in Telephony;" one from Mr. John Gott on "The Mirror Galvanometer and Scale;" and one from Mr. Fred. A. Hamilton on "Slipping Buoys from Cable Ships." The abstracts from foreign periodicals contain matter of interest.

Electric Lighting in Chelsea.—At a meeting of the Chelsea Vestry, on Tuesday, a letter was read from the Board of Trade, in which it was stated that the Chelsea Electric Lighting Provisional Order promoted by the Metropolitan (Brush) Electric Lighting Company would be considered to-day (Saturday). The matter was referred to the Electric Lighting Committee, who were empowered to take all necessary steps for the protection of the interests of the parish. It was stated that this is the first case to be taken under the Electric Lighting Act, and it was understood that the vestry would be represented by Mr. C. Mossop, the chairman of the Electric Lighting Committee, and Mr. G. H. Stayton, C.E., the surveyor to the vestry.

The Transmission of Power.—The subject of M. Marcel Deprez's experiments occupied the attention of *The Times'* Paris correspondent this week. We have already expressed our opinion on these experiments, and would not refer to them again, but for the sanguine way in which the above correspondent treats the matter. He says, "In one of the experiments the force was transported 35 kilometres, and having been of 10 horse-power at the starting point, it was still 5 horse-power at the point of arrival." We think *The Times'* correspondent is mistaken, and until we are proved to be wrong, must reiterate our previous statement, founded on the evidence of eye-witnesses of the experiment, that not more than one-third, if so much, of the horse-power put into the sending machine came out of the receiving one.

Reinforcing Telephonic Currents.—At a recent meeting of the French Physical Society, Mr. James Moser communicated his method of reinforcing telephone currents. It consists in connecting induction coils and receivers, partly in series and partly in quantity, like the elements of a battery. For example, in transmitting music from the Hippodrome to the Place Vendôme, on a recent occasion, Mr. Moser joined up 24 coils as follows:—4 in series, 6 in quantity; and 100 receiving telephones, 6 in quantity and 16 to 18 in series. Two theories point to an arrangement of the induction coils in opposition to one another; tension is necessary in order to get the maximum return and useful effect, and quantity is necessary in order to get the minumum lateral losses, condensation, absorption, &c. In fact, Mr. Moser's plan is to arrange the elements of telephonic circuits in the same way that the elements of a battery are arranged in order to obtain the greatest effect.

The Grievances of Telegraph Clerks.—A meeting of telegraphic clerks employed at the Exeter post-office was held in that city on Saturday last, for the purpose of considering the scheme of revision lately applied to the telegraph service, especially as it affected Exeter. The meeting was largely attended, and resolutions were unanimously carried expressing dissatisfaction with the scheme, inasmuch as it had failed in many important particulars to satisfy the just claims of the telegraph clerks as advanced in their petition to the Postmaster-General in 1881. It was also resolved to support the central committee of the Telegraph Clerks' Association in its proposed attempt to obtain sanction for a Parliamentary Committee of Inquiry into the many questions affecting the welfare of the telegraph service which still remain open, and to use every other legitimate means to obtain a concession of the claims put forward. A meeting of telegraph clerks was also held in Newcastle on the same day, when resolutions of a similar character were enthusiastically passed.

Spectrum of Carbon.—In a recent communication to the Royal Society, Professors G. D. Liveing and J. Dewar communicated the results of spectroscopic investigations of carbon. Photographs were taken of the spark of a large induction coil between poles of purified graphite in air, carbonic anhydride, hydrogen, and coal gas; the wave lengths were determined by a Rutherford diffraction grating, having 17,296 lines to the inch, and found to be for the principal lines—2,296·5, 2,478·3, 2,509, 2,511·9, 2,836·3, and 2,837·2. When the spark was taken in air, the photographs showed, besides the carbon lines above, the six cyanogen flutings in the blue, and those between K and L, and near N, but this practically disappeared when carbonic anhydride was substituted for air. The spectrum of Swan's incandescent lamps was examined and found to be continuous until the thread gave way, when the characteristic green flutings of carbonic oxide appeared; in some cases a sort of flame appeared at the positive electrode when the current was not quite intense enough to rupture the thread The spectrum of the rarefied atmosphere within the envelope of the lamp revealed the presence of carbonic oxide. By interposing different flames between the incandescent lamp and the slit of the spectroscope, a comparison could be made of the probable temperature of the flames and filament, and from the experiments it is inferred that the emissive power of the carbon thread for light of the refrangibility of the D lines is approximately balanced by that of sodium at the temperature of the flame of cyanogen burning in air, but is sensibly less than that of sodium at the temperature of a jet of coal gas or hydrogen in oxygen. It is thus probable that the temperature of the incandescent thread is not far different from that conveyed to sodium by the cyanogen flame burning in air.

The Mirror Galvanometer and Scale.—In the January number of the *Journal of the Society of Telegraph Engineers* Mr. John Gott describes the following new scale for use with the mirror galvanometer, which he has found to answer well, and render inappreciable movements of the mirror visible. "Select," he says, "an ordinary toilet mirror—the clearer the glass the better; this quality can best be judged of by removing the frame and holding the

Digitized by Google

glass up to the light and looking at the edge; if it has a deep blue tinge reject it. The thinner the class the better—one-tenth of an inch is a good thickness. The backs of some mirrors have a coating of varnish, and these are to be preferred, as less likely to have the silvering damaged by friction in handling. Cut off a strip 2½in. or 3in. in width, and, say, 15in. long. The surface of this is to be frosted by rubbing with a piece of glass about an inch square, supplied with fine emery powder and water; a small handle may be cemented to this piece with Chatterton's compound. After the frosting is completed, the strip may be framed with dark wood, and hinged at the back to a rod, so as to be movable around its centre, elevated or lowered, and inclined—in fact, it should have a universal motion, so that it can be adjusted to any focus. When the scale is five or six feet from the galvanometer (the lamp with its lens being, as is usual, much nearer), the spot may be said to be equally bright at all parts of the scale. For shorter ranges it is desirable to use a scale bent to form an arc of a circle whose centre is the galvanometer. Such a scale can be graduated by engraving on the glass; but as the frosted surface can be written upon with a fine pen and ink as readily as upon paper, any grading can be adopted, and, if necessary, be removed by washing. Transparent scales have been for some time in use; this reflecting scale possesses advantages over them which are obvious."

Magnetic Observations at Kew Observatory.—We take the following from the report of the Kew Committee of the Royal Society:—"The Magnetographs have been in constant operation throughout the year. In March a new suspension pulley was fitted to the bifilar magnet in order to reduce the distance between the suspension wires from 6·8 millims. to 5·5 millims., and thus to increase the sensibility of the instrument. This change was recommended by Professor W. G. Adams, in order to make the scale-value about ·0005 millim. mgrm. for 1 millim., as suggested in his report to the British Association last year. Dr. Wild, of St. Petersburgh, also recommends that all observatories should adopt, as far as possible, the same uniform scale for their instruments, and suggests that the scale-values should be as follow:—For the declination, 1 mm. $\delta D = 1'$; for the bifilar, 1 mm. $\delta H = 0{\cdot}0005$ mm. mgr. units; for the balance, 1 mm. $\delta V = 0{\cdot}0005$ mm. mgr. units. The following are the values of the ordinates of the various photographic curves as determined at the various dates stated:—Declination 1in. = 0° 22′·04. 1 mm. = 0° 0′·87. Bifilar Jan. 3, 1882, for 1in. $\delta H = 0{\cdot}0450$ foot grain units; for 1 mm. $\delta H = 0{\cdot}0008$ mm. mgr. units; bifilar Mar. 27, 1882, for 1in. $\delta H = 0{\cdot}0222$ foot grain units; for 1 mm. $\delta H = 0{\cdot}0004$ mm. mgr. units; Balance Jan. 6, 1882, for 1in. $\delta V = 0{\cdot}0341$ foot grain units; for 1 mm. $\delta V = 0{\cdot}0006$ mm. mgr. units. The committee having been asked by the secretaries of the International Polar Commission to furnish that body with copies of their hourly determination of the magnetic elements, recommenced the tabulation of the curves which had been suspended in 1879. (See Report for 1880, p. 4.) With a view, however, of reducing the labour of tabulation, it was decided that a sufficient degree of accuracy and greater rapidity would be obtained by reading the curves by the unassisted eye, without the aid of the tabulating frame and vernier hitherto employed. Scales graduated on glass plates have, therefore, been prepared; and the curves tabulated from August 1 up to the present date by this means, the declination being recorded to a tenth of a minute of arc, and the force-traces to the tenth of a millimetre. In order to obtain a record of the more rapid changes which take place during magnetic storms, a trial has been in progress since July 4 of the highly sensitive argentic gelatino-bromide photographic paper prepared by Messrs. Morgan and Kidd. The results of the experiment show that the paper indicates clearly small movements of the magnet which the waxed paper is unable to register, and also that less gas-light is needed for the purpose of illumination."

Electric Railways and Electric Lighting.—At a recent meeting of the Institution of Civil Engineers of Ireland, on the occasion of a discussion on Mr. Fahie's paper on dynamo machines, some interesting statements concerning both electric railways and electric lighting were made. We extract the following from a report which appeared in an Irish newspaper:—"Dr. Traill said that the principle on which their cars (on the recently-constructed Portrush Railway in Ireland) was running was not exactly the same as that on which the little machine before them was moved. Their first experiment was on that basis (using one rail for the positive and the other for the negative current), though they could hardly have anticipated that it would be possible to send a current through one rail and down another a distance of six miles. If the wheel of the car met with an interruption the current might be broken. When they passed one mile they saw they could hardly depend for conducting power the rest of the distance, and what they did was this—they put down a third rail, about 18in. high, a little on one side, and they had that rail completely insulated for a distance of 2½ miles. They found that paraffin oil and sawdust formed a complete non-conductor of electricity. Even in the wettest weather the insulation for 2½ miles was uninterrupted, and he had not the slightest doubt that before long it would be equally perfect for the whole distance of six miles. Their large car was about three tons weight, and they ran those cars on an ordinary up-and-down-hill road, the incline on which was in some places 1 in 35 and 1 in 40. Within a few months, when they applied water to generate the current, he believed they would be able to run their cars the whole distance, and that the success of the railway was assured.—Mr. Aspinall said that electricity had done a great deal for gas. But for electricity they would not have those magnificent burners which they now see in various places. He could tell them what had been done at the Great Southern and Western Railway Works within the last eighteen months. They were lit entirely by electricity, and one great reason for their success was this, that they had not got gas to fall back upon, and they were obliged to depend on the electricity. They had six dynamo machines running there—four small ones and two large—and each of the latter was able to drive a light equal to 3,000 candles. The light was used in the workshops, and for shunting purposes it did extremely well. He should be sorry to go back to gas, unless they got an equivalent light. As to the question of expense, an equal amount of light from gas would cost them a great deal more. Taking the expense of working, of coal fuel, the maintenance of machines, men's wages, interest on capital expended, it did not cost them for each hour they ran the light more than 8s. If Mr. Browning (engineer to the gas company) wished he would show him the cost of machines, from the first moment of their being worked down to the present."

Action of Currents on Chlorides and Chlorates.—The following abstract of a paper on this subject by Messrs. A. Lidoff and W. Tichonieroff in the *Journal of the Russian Chemical Society* for 1882, pp. 341-9, appears in the February number of the *Journal of the Chemical Society*:—"In a former paper the authors have found that by the action of

Digitized by Google

the electric (galvanic) current on a solution of chlorides, hypochlorites are first formed, which by an elevation of temperature are converted into chlorates. But later on they found that even at the ordinary temperature, as soon as the solution becomes more concentrated, hypochlorites are converted into a mixture of chlorate and chlorides by the sole action of the current. They propose to apply this process to the manufacture of chlorates, more especially of the sodium salt, which is difficult to prepare in the ordinary way. On acting with a current of a powerful Gramme machine for 25 hours, on a solution of 400 grams of potassium chloride in 900 grams of water, 210 grams of crystals, 70 per cent. of chlorate was obtained. The crystals contain, together with potassium chlorate, a considerable quantity of the chloride, and 5-12 per cent. of carbon from the electrodes. As soon as about 30 per cent. of the original salt is transformed into the chlorate, the positive electrode is most strongly corroded, and no further separation of the crystals from the liquids takes place. If, instead of a high tension current (2 electrodes), a divided current (8 electrodes) is employed, far less chloride is converted into chlorate in the same space of time. The corrosive action of the liquid on the positive electrode is due to its oxidation by the oxygen of the potassium chlorate, which is reduced to chloride (about 30 per cent. in 10 hours). For this reason potassium chloride cannot be completely converted into chlorate, but a limit is reached after some time, when the energy of formation of potassium chlorate from the chloride becomes equal to the energy of its decomposition. Electrodes of another material than carbon cannot be used for the conversions of chlorides into chlorates, for all metals, even platinum, are corroded by the chlorine which is set free at the same time. If, however, a solution of potassium *chlorate* be electrolysed by means of platinum electrodes, no chlorine, but *ozone*, is evolved on the positive pole. At the same time crystals of potassium *perchlorate* separate from the liquid, and only traces of potassium chloride are formed at the same time. In this respect the action of electricity on potassium chlorate is analogous to the action of heat on the same salt; in both cases oxygen is evolved, and potassium chlorate and chloride are formed, although the proportion in the quantities of these two salts is widely different. The corrosion of carbon in the above case is due to the action of ozone, and the products of this action in presence of water are mellitic and hydromellitic acids."

Will a Current Traverse a Vacuum?—In the *Philosophical Magazine* for this month will be found a translation from the *Kongliga Svenska Vetenskaps Akademiens Handlingar* of Professor E. Edlund's "Researches on the Passage of Electricity through Rarefied Air." At the beginning of this paper Professor Edlund says:—"If r is the obstacle to the propagation of electricity which is situated at the point of passage between the electrodes and the gas, r_1 the electric resistance in a column of gas of unit length, and l the distance between the electrodes, $r + r_1 l$ will be the sum of the resistance which the electricity must overcome in order to pass from one electrode to the other. Of these values, r increases continually in proportion as the gas is rarefied, while r_1 during the same time undergoes incessant diminution. From a judicious interpretation of the experiments which have been made, especially those of Hittorf, it follows that the augmentation of the first of these quantities and the diminution of the other continued until the gas had arrived at the greatest rarefaction it was possible to obtain by means of the mercury pump employed. In the space exhausted of air, r acquires such a value that it is impossible for the current to surmount it. If, then, the current cannot traverse a vacuum, it is not because the value of r_1 of the resistance has become too great, but because r is augmented to such a degree that the current is incapable of surmounting it. Several properties of gases with respect to the passage of electricity show that this interpretation of the resistance which they oppose to its propagation is really the only true one." Dr. Edlund then goes on to repeat an opinion previously expressed by him that "the principal obstacle encountered by the electric current at the surface of passage between the electrodes and the rarefied gas is due to an electromotive force producing a current in the opposite direction to the principal current." Having described a number of experiments undertaken to prove the correctness of his opinion, Professor Edlund concludes by reasserting it, and says:—"It has been observed that the negative pole is strongly heated in a space of rarefied air, and that, *cæteris paribus*, this heating is augmented with the rarefaction of the air. I have, in a previous memoir, proved that, when a current traverses an electromotor in an opposite direction to the current which the electromotor tends to produce, there results from it an evolution of heat proportional to the electromotive force multiplied by the intensity of the current. Now since (according to what precedes) the electromotive force e in the spark is notably augmented with the rarefaction, it follows that the heat evolved at the negative pole must be increased when the rarefaction is increased, which accords with the results of experiment. Here it should be remarked that in the voltaic arc it is the positive pole that is most strongly heated, from which we may be authorised to conclude that the electromotive force, shown by irrefutable proofs to exist in the voltaic arc, has its seat at the positive pole. This force is not thermo-electric, and it is not produced, as M. Le Roux assumes (vide *Comptes Rendus* XCII., p. 710, 1881), by one of the poles being more highly heated than the other. On the contrary, it is the electromotive force that is the cause of the heating. It has been proved that the force continues to exist, even if the negative pole of the voltaic arc be heated by a Bunsen burner, or in any other way, so as to become hotter than the positive pole. The researches of which I have just given a brief summary confirm, therefore, in all respects, the results to which I had already been led by my examination of the observations of other physicists on the passage of electricity through rarefied gases. The maximum attained by the current-intensity at a certain pressure of the air when a current traverses a space of rarefied air is not due in any way, as it has been generally assumed to be, to the resistance $r_1 e$ of the air having its minimum at that pressure, and afterwards increasing in amount with the increase of rarefaction, but really to this—that the sum $e + r_1 e$ then possesses its minimum value. With the continuation of the rarefaction the resistance $r_1 e$ continues to diminish, while e incessantly increases; consequently the circumstance mentioned above, namely, that the induced current possesses its maximum value at a certain pressure of air, gives no support to the allegation that in highly rarefied air, or in a vacuum, the resistance is sufficiently great to prevent the current passing. Here it is not the resistance of the gas, but the electromotive force e_1 increasing with the rarefaction and connected with the electrodes, that presents an obstacle to the passage of the current. Everything is in favour of the hypothesis that vacuum opposes a very feeble resistance to the propagation of electricity."

A GUIDE TO PRACTICE IN THE SUBMARINE CABLE TESTING ROOM.

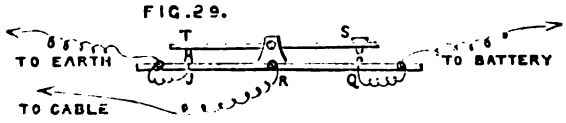
No. XIV.

The form of arrangement for the connections in the joint test suggested in the two last numbers may be open to objection on the ground of having more contact points than are absolutely necessary, and a comparison with the figures given in this number will afford a means of determining the question which plan is likely to present the fewest obstacles to good insulation, and to avoid any interference of one section of the operation with another. Facilities in connecting up need not be taken into account, for we have supposed the arrangement to be made specially with a view to confining it always to this one purpose, and when once in order at the commencement of manufacture of a long cable, to remain unchanged to the end.

The first of the two diagrams of connections shows a mode of joining up with one earth communication, and the second is much the same, but there is no connection with the earth. Many operators prefer this latter arrangement, for reasons which will presently appear. Let us examine Fig. 30, and see how the objects attained with the connections in the former figures are gained by means which at first sight appear to be different.

We have here, as in the first plan, two separate keys. In Fig. 23, &c., there were practically two Lambert keys, one of which served to charge and discharge the cable, and the other was employed for observing the action of the trough (or the water) in their relation with the joint. The two keys in Fig. 30 exactly replace these other two in one view; one of them is a Lambert key, and the other, properly speaking, is a discharge key. Figure 29 gives a view of its action

FIG. 29.



Side View of Key in Fig. 30.

which might not be so clearly apparent in the smaller illustration. The stand is of insulating material, and the brass bar is pivoted at R, where connection with the cable is made, and has two contact points, that at J being, in the key's normal position, in contact with a similar point which connects to earth. At Q a contact which connects one battery lead brings the latter into communication with the brass bar when depressed, and the other battery pole being to earth through J, a charge is thus sent into the cable through the point R. The Lambert key has a connection F, which enables us to put the trough directly to earth, which may pass for an advantage compared with the first arrangement, where it could only be earthed through the galvanometer.

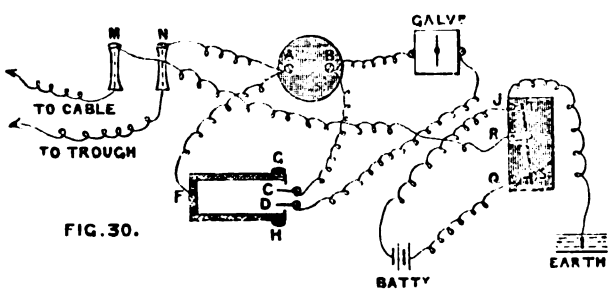


FIG. 30.

Joint Test; One Earth Connection.

The conditions, however, would be equal if the galvanometer in Fig. 23 had a short-circuit arrangement, which we have not represented, because for this purpose, with the plan there suggested, another key or connecting piece would have been necessary. In the case now before us the point G is kept down on C during the interval between tests, but not with the object of putting the trough to earth. This contact is only necessary for a reason referred to in our remarks on the test in the last number. It answers the same purpose as having a plug for joining the two poles of the condenser. When G is not put down the poles are separated, but by depressing G on C, the lead (A F G C B) joins the poles, and both are put to earth by the earth lead wire. The condenser in this figure may be supposed to have no plug arrangement. Another point in which this plan differs from the first is that the cable is kept to earth at every moment except when it is charged, that is to say, of course, from the time when it is connected for the test. This is really an advantage, and is effected by the bar from R to J at the key. On looking at this key in either figure, 29 or 30, we see that on depressing S, and thus joining the battery lead to the key, the point T is separated from J, and the centre piece R remains fixed, so that the cable can be joined either to the battery or earth separately. But in Fig. 23, &c., the cable is disconnected from earth until the key piece A is depressed. The pieces M and N may be two ebonite pillars, somewhat similar to those mentioned in No. 1 as being fixed on the large commutator; their leads, and most of the others joining the several keys, &c., may pass through holes and lie under the surface of the table. One pole of the battery is always to earth through J; one condenser pole has the same earth connection, the other condenser pole by being joined to F can be put to earth by depressing G, or connected to the galvanometer by putting down H; this pole is also joined directly to the trough through N, and the galvanometer connects with earth by the lead through B to J. This arrangement is as neat, and at the same time as complete, as we could wish in a case where an earth connection is used for the test.

We commence, as before, by testing the insulation of the trough, and may first follow the same course by shifting the lead from M to N (Fig. 30), and depressing first H, and then instantly putting down S, thus getting an immediate discharge from the trough, and afterwards repeating the operation, but depressing S for a minute before touching down H, and compare the deflections. But instead of removing the lead from M, we may judge if the insulation is sufficient by connecting the galvanometer to the condenser and trough, through depressing H; only on repeating this two or three times we ought to have little or no deflection as a final result. This at first sight appears to be assuming rather than testing the insulation of the trough, or, it may not be clear to the learner how we expect this mode of observation to afford any certain information; although if there be a charge it will be made evident. Let us see, then, what the action is. We will first short-circuit the condenser by depressing G, and thus entirely discharge it, then releasing G, touch down H, and if a deflection results it will be owing to a remnant of charge in the trough, which should thus be discharged through the galvanometer to earth. If, now, on releasing H and again touching it down a much less deflection or none at all occurs, we conclude that the trough is quite discharged and also well insulated. If, on the contrary, an equal deflection followed the second touch down, or if on holding the key down a permanent deflection appeared, we must attribute it to the reception by the trough of a charge from some other source; this must be through communication with the earth. For the condenser was perfectly discharged at first, and the trough would have also been cleared at one contact. The consideration of the point is not a mere matter of curiosity or uncertainty either. Experience has shown the existence of the facts, and the joint test is in certain respects so peculiar that it is not safe to neglect any indications, even if they seem to be anomalous. We have already said that we believe this is not as definite or decisive as other tests—shall we say, also, not so well understood?

We will, however, now suppose the trough to be well insulated. Then, after short circuiting the condenser for a moment, we should touch down H and immediately afterwards S, and observe the deflection; H would then be released and S clamped down for, say, one minute. It is to be noted that H must be depressed before S, that the effect of the inductive charge on the galvanometer may be exactly coincident with the direct charge of the cable, that is, that the path may be open all through, as it were. At the end of the one minute H is to be touched down and released, and

Digitized by Google

the deflection noted. The battery is still kept on, however, for another minute, when H is again touched down; the deflection now given must be much smaller (little or nothing) in comparison with that for the first minute, and if so, the battery key is released, while H is kept down for a moment, and the deflection for the inductive discharge should be in the opposite direction to that of the other three, but equal in amount to the first.

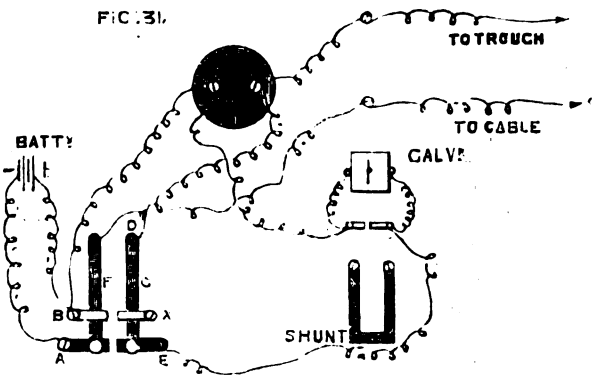
It sometimes happens that the deflection for the second minute is as large or larger than that of the first minute. Speaking generally, we should from this conclude that the joint was bad, from the fact of so much fresh leakage after being discharged a minute before; but it is not necessarily the case, and it is better to leave the battery key down for a third minute, and observe a third time, when the deflection may be satisfactory. This shows the peculiarity of the test, and seems to be contradictory; it is generally explained vaguely as being due to "inductive disturbance," but if the final result appears correct, it may be accepted without trying to account for it. If, however, the third minute shows no improvement the joint cannot be passed, but as we are just now assuming our test to be satisfactory, the consideration of this difficulty with others that may appear is postponed for the moment. The action during the course of the operation is easily understood by looking at the figure. The cable is charged whilst S is down, and the leakage from the joint passes to the condenser, whence the accumulation is discharged through the galvanometer to earth on depressing H. The details are all made plain by the preceding explanation of the connections.

We will next proceed to consider the operation with connections arranged without earth communication. The learner might have been in some degree prepared to understand this method at first sight if we had followed the principle in connection with the capacity test which is sometimes taken without earth. We purposely omitted this at the time, but may say briefly that the difference between using and not using earth is this:—Instead of putting one pole of the condenser to earth in order to charge it we bring one pole to communicate with one battery pole, and the other with the other pole; the battery, of course, has no earth in this case. Further to produce a deflection from the accumulation in the condenser, each of its poles communicates with either terminal of the galvanometer coil, this latter also having no earth. To answer the objection naturally occurring to the learner that a condenser cannot be charged unless one pole is to earth (as we impressed on him in No. VI. and VII.) we must explain as simply as possible how this comes about. The condition is a *sine quâ non* only when one pole of the battery is to earth, in which case the circuit is completed by means of the two earth connections. This circuit which exists in all cases of electrical action is said to commence at the + pole of the battery, and to be completed at the — pole. The action may be most conveniently explained by quoting some words from a book published some years ago, but now out of print, and whatever theory may be preferred we have here a view which suits our purpose better than any other*:—"Whenever electrical generation occurs there always exists, besides a source of generation, at which the normal electrical equilibrium is first disturbed, certain conditions which allow the positive and negative electricity to recombine, or else certain other conditions by which the electricity generated is accumulated on two surfaces separated by a medium through which it either cannot recombine, or only so less rapidly than the source can generate." The case of a good conducting body outside the battery, or a conductor which is uniform and unbroken throughout answers the first of these propositions, and that of a condenser whose two poles are connected directly to the battery poles represents the second, and, further, it is only necessary that there should be a means of recombination, whether the earth form part of the circuit or not, so that in charging a condenser with one pole to earth we have again an illustration of the first of the above two propositions.

In thus defining the action in an electrical circuit we wish to state distinctly that we use the explanation as the best mode of expressing what we cannot decisively pronounce upon.

We will now consider the plan of connections in Fig. 31. One key only is used, namely, a double-current split key. Its action is similar to that of the double-current key already illustrated, but there is no communication between the two

FIG. 31.

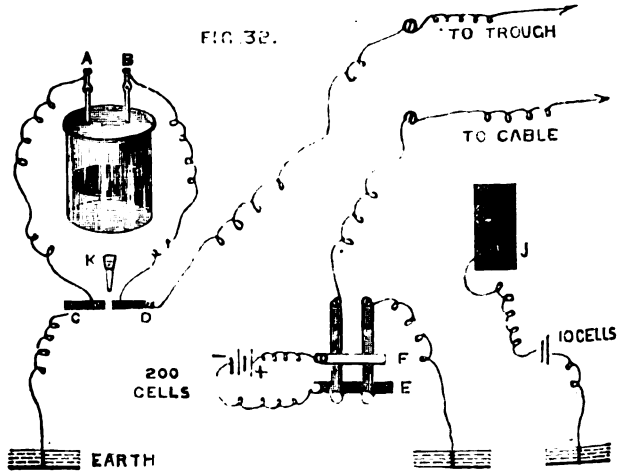


Joint Test; No Earth Connection.

opposite sides. The end contacts C and D lead to the condenser and cable respectively, the battery leads are joined to A and B, and the galvanometer to E. When F is depressed the bar is separated from B, and the cable is charged from A. The circuit may then be traced through the joint to the trough (or the water) and so to the condenser pole I. The other condenser pole H connects with the opposite battery pole by B. This replaces the earth arrangement in Fig. 30, where one condenser pole and one battery pole is put to earth. In a similar way one terminal of the galvanometer is connected directly to this pole of the condenser instead of to earth as in Fig. 30. The point X in the key is not used in this test. The course of proceeding is seen at a glance after the explanations already given. We first depress G on E, and instantly touch down F and mark the deflection (the inductive charge); then, releasing G, clamp down F and depress G again after three minutes if one leakage deflection only is required, or after one minute and two minutes if taking two separate deflections. Then, keeping down G, release F, and we have the inductive discharge. We have added a shunt in this figure, but it is not needed more in this than in the other arrangements; it may or may not be convenient to use it. It appears unnecessary to say any more at this point on this test as taken with the galvanometer; we have yet to illustrate the operation when using the electrometer.

In Fig. 32 we have suggested an arrangement for this pur-

FIG. 32.



Joint Test with Electrometer.

pose which shows the principle clearly enough, though the connections might be variously made. The action will be understood by referring to the remarks on the use of the electrometer in No. V. The rise or fall of potential in any electrically charged body is observed by connecting it to one pair of quadrants, the other pair being to earth. The insula-

* "Electrical Accumulation and Conduction," by F. C. Webb.

Digitized by Google

tion of the trough is determined by noting the fall and the goodness of the joint by watching the rise (or rate of rising) of the potential in the quadrants. The dotted line in the figure represents a lead which may be connected temporarily or otherwise for testing the insulation of the trough. The key G H is for charging and discharging the cable. The test is taken as follows:—The plug K being inserted, the key J is depressed, and the pair of quadrants B is charged from the separate small battery of 10 cells along with the trough (or the water in it). On removing the plug a deflection results, representing the potential of the battery. If the trough were *perfectly* insulated this deflection would remain permanent as long as the battery key J is kept down, but any conductive communication of the trough with earth would cause an escape of part of the charge, and the potential will fall; the deflection will tend backwards towards zero. The insulation should be good enough to allow of only one or two divisions for this fall. If this is all right the plug is inserted and the key J released. We should have said that this trough test would generally be taken before putting the joint into the water. Removing the added trough lead, and again lifting the plug, the key G is now touched down, the cable is charged from the large battery, and an induced charge causes a deflection which may or may not be regarded. The plug is replaced and the battery key clamped down. The charge will leak at the joint according to its quality, and on removing the plug again the quadrants to which the trough is connected will acquire the potential of the water. The greater the leakage from the joint the higher will this potential be. The time for continuing the charge and the amount of deflection allowed will have been decided previously. If the discharge is to be observed, the key G will be released without reinserting the plug K, which is returned at the end of the test.

The joint test with the electrometer is considered more decisive than those with the galvanometer and condenser, but the latter are more generally employed. The analogy between the two modes of testing is this. When using the galvanometer the leakage from the joint accumulating in the condenser measures or represents the potential, since, the battery being kept on, the amount escaping is being continually replaced by it. With the electrometer we observe the potential *directly*, by comparing that acquired by one pair of quadrants with the earth or zero potential of the other pair.

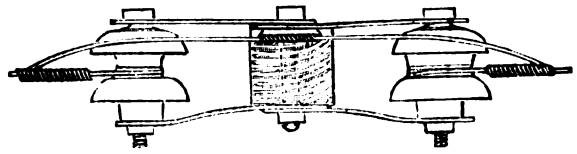
Before concluding these chapters on the joint test we must mention a few difficulties that may arise, and add a caution or two for the benefit of the learner. In the first place, the dimensions of the joint itself is a point worthy of attention. If it be too large (too thick) the consequences may be serious. Joints have been known to be squeezed on this account when passing through the sheathing machine, and in some places it has been the custom for the electrician to gauge every joint before testing, using a metal gauge through which it must fairly pass. The jointer should have previously done so with an exactly similar gauge; but, without wishing to insinuate anything against their correctness, we must hint that the jointer's gauge sometimes passes freely over a joint which the electrician finds too large for his own; he will do well to remember this. In the next place care should be taken that the trough should be perfectly clean and rubbed dry the last thing before commencing the test. For this may have been done some time before, but the atmosphere may be very damp, and the dust of the shop may cling to its surface and form minute chains for leakage to earth. In very damp weather, also, the leads should be wiped as dry as possible for the same reason; and in all weathers, damp or dry, the core for a few feet on either side of the joint must be well dried. It may further happen at times that a test shows by too large a deflection an apparent weakness of the joint. This may be the result of the cause just mentioned, very wet weather, for which allowance is permitted to be made, but if the matter appears in dry weather, it is well to go out into the shop and examine the arrangements of the trough, &c. Perhaps it may be found to have been placed on wet ground; it may be surrounded by water lying about. The boys employed in the core tanks are often very careless in this respect, and allow the hoses attached to the tanks to run over the ground and produce this evil result.

One more point is worth noting, and involves in its consideration a general caution for insuring, as far as possible, the correctness of all the arrangements. The jointers' box or office is generally above the floor, and the two ends of the coils to be united are passed up to the window-hatch. He has simply to join these two ends; other hands have the duty of selecting the proper ends, and, as a rule, a mistake scarcely ever occurs. But it has been the fact that a wrong coil has been selected, and its end joined out of its proper place. The two ends of one coil have even been jointed together owing to a mistake of this nature. We repeat, such errors are rare, but being possible, it is well for the electrician to be as active and thoughtful as he can in assuring himself that everything has been duly prepared.

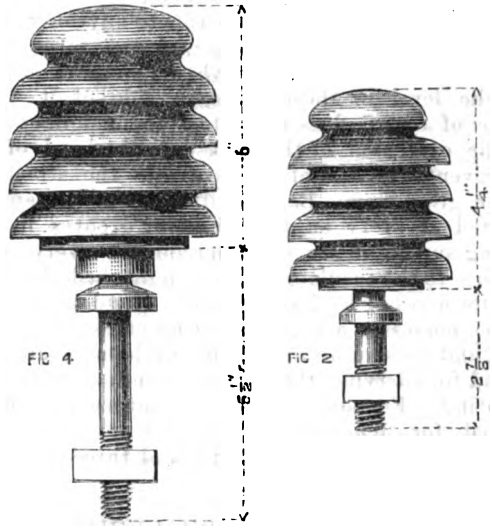
BENNETT'S INSULATORS.

Early in 1882 Mr. Alfred R. Bennett designed the two insulators illustrated herewith, his object being to improve the insulation of the lines erected for the National Telephone Company by Messrs. D. and G. Graham, of Glasgow. The wires taken over by the National from the late Bell and Edison Telephone Companies and others were seriously

FIG 1



deficient in this respect, so much so that overhearing between wire and wire was common, and in many cases was obviously due, not to induction, but to actual leakage. These wires were all constructed on the double-shackle system, which, indeed, before the introduction of the insulators now under consideration, was the one universally adopted for over-house telephone lines in this country. The double shackle is shown in Fig. 1. It consists of two porcelain cups having iron bolts right through them, which bolts are connected by four galvanised iron bands or straps, with a third bolt passing



through the support. The ends of the spans of wire are looped round each cup and joined by a soldered cross-connection. This arrangement has much mechanical merit, for it confines the effects of a break in a wire to the span upon which it occurs, and prevents the wire falling into the street in the event of a fracture of a porcelain cup. But its insulating properties are very inferior, for at each cup the current finds two roads to earth, which, everything else being equal, would, by the law of derived circuits, reduce the insulating efficiency of a single shackle cup to one-fourth of that of an upright insulator, and of the double-shackle to one-eighth. But in practice, especially in

Digitized by Google

wet weather, the superiority of the upright, even if only a single-shed, is very much more marked, for the shackle has no inner cup, and no part of it can be kept even approximately dry. Probably a good double-shed upright insulates at least thirty times better than the double-shackle, its large effective dry surface being wholly in excess of the gain of eight times derived from the position of the wire at its summit and the existence of only one road to earth. A combination of the mechanical functions of the shackle and the insulating properties of the upright was, therefore, required, and this Mr. Bennett appears to have accomplished in his design. The insulators shown in Figs. 2, 3, 4, and 5 are used in precisely the same way as shackles, each span being terminated round the insulator, and joined through to the next by a soldered cross-connection. (Fig. 6.) When light wire, such as Nos. 16 to 20 phosphor-bronze, is employed, both spans are terminated round the topmost groove. With heavier wire it is better to terminate each span in different grooves, preferably the first and second from the top. When unusually long spans are unavoidable it is well to reduce leverage by

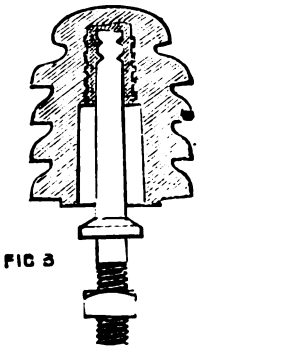


FIG 3

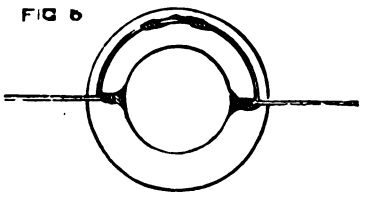

FIG 6

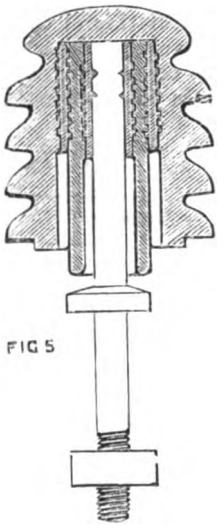

FIG 5

using the second and third or even the third and fourth grooves, the insulation under these circumstances, owing to the dry cup, still being far superior to anything obtainable from shackles. The terminating of the wires round the lower grooves is also advisable when a support chances to be below the level of those on each side of it. Thus the breakage of a span does not affect the neighbouring ones, while the extension of the stalk into the head of the insulator prevents the fall of the wire into the street when an insulator gives way. Besides allowing of the spans being terminated at every support the four grooves increase the insulating surface materially, and impart a very ornamental appearance to the insulator. The single-shed (Figs. 2 and 3) is used for wires of moderate length. The double-shed (Figs. 4 and 5) possesses a high insulating efficiency, is very substantial, and does admirably for long telephone and telegraph lines, and for carrying the heaviest conductors used in electric lighting. Economically, the insulators leave nothing to be desired, for each upright, with its bolt and nut, replaces two shackle-cups, four iron straps, and three bolts and nuts.

THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

At the meeting of this society, held on Thursday evening, 8th inst., Mr. Willoughby Smith in the chair, two communications were read by the secretary relating to the magnetic storms and the earth current disturbances of last year. That from Mr. J. GRAVES, member, described the effect upon the cable between Valentia and Heart's Content on 17th and 18th November, 1882, the observations being taken at Valentia. The second paper was from Mr. E. O. WALKER, member, giving the results of observations on a magnetic storm in India, which occurred 12th September, 1882, and also some general remarks upon earth currents. In respect to the latter Mr. Walker stated that the observations made in India did not appear to confirm those taken in England, the electrical disturbances varying considerably in direction, and having apparently no connection with the moon's variation. Both papers were diagramatically illustrated, copies of which showing the curves of disturbances as indicated by galvanometer, being distributed among the members.

Mr. ALEX. J. S. ADAMS, associate, then read a paper on "Earth Currents, Sun Spots, and Electric Storms," being the third paper on this subject which Mr. Adams has contributed to this society. After referring to the several theories which had been held to account for the appearance of sun spots, and to the facts as to their apparent effects, Mr. Adams described particularly one phenomena connected with the spots observed during the month of November last. They were visible even to the unassisted eye, and were not fixed, but moved from east to west, contracting or enlarging as they neared the margin on either side of the sun's face. They disappeared over the eastern margin, and then reappeared, diminished in size, after an interval of about a fortnight on the western side. During a portion of the time these spots were visible great perturbations were observed in the electrical condition of the earth, a condition which he assumed to be normally constant, and, therefore, left the telegraphic systems in equilibrium, but which was liable occasionally to marked and even serious disturbance, so much so as to interfere and even interrupt all telegraphic signalling within the area over which the storm, as it was called, extended. That such a disturbance was likely to arise from every alteration in the condition of the heavenly bodies near enough to influence this earth Mr. Adams had already shown in former papers; and he had further suggested that those disturbances which are regular or periodic might be ascribed to the ever-changing position of the moon, and to the difference between its speed of revolution and that of the earth. That the cause of these disturbances is external to the earth, and not within it, Mr. Adams thought was evident from the circumstance that the effects were observable with the same regularity, and at the same moment of time, all over the world. He had carefully observed the effects on the telegraph lines between London and Leicester, and London and Leeds, during the great magnetic storm of last November, and of the curves of disturbances on the 17th of that month he now submitted diagrams. The sun spots were at that time conspicuous, and it was impossible to avoid the inference that the two phenomena had some connection. It was noticable, however, that the disturbance in the electrical condition of the earth did not conform to the passage of the sun spots—that is to say, the earth currents did not last during the whole period, but only for one portion of it. It occurred to him that this might be explained by assuming that the sun's atmosphere interfered with the electrical influence exerted by the sun's body upon the earth, and that possibly the dark spots were breaks or rifts in the sun's atmosphere. If that were so, then the earth would be subject to the direct action of the sun, only when the spots, or gaps in the sun's atmosphere, were centred on the earth. The sun's revolution occupies twenty-five days, and consequently the spots were visible to us for half that period, say twelve days. If, then, his theory were correct, the magnetic storm would be highest on the sixth day after the appearance of the spots: that is to say, when their position centred on the earth; and this is what really occurred. On the 12th November the spots made their appearance; there was then no electrical disturbance observable, and none till the 17th, when it burst upon us and lasted with varying intensity for three days, disappearing altogether on the 21st, the sun spots, however, continuing in sight for five days longer. The inference he had drawn from these observations was confirmed by the reappearance of the spots, diminished in intensity, on the 9th of the following month, earth currents becoming troublesome six days after, as on the former occasion, that is to say midway between the first appearance of the spots and their disappearance. If his conjectures proved to be correct, then it would in future be possible for astronomers to predict when we may expect these magnetic storms or earth current disturbances.

Professor ADAMS, while complimenting the society on the interesting paper to which they had listened, feared that the facts were not yet so complete as to justify us in basing any theory upon them. He considered it very remarkable, however, that by comparing the magnetic disturbances recorded in 1880 at many places remote from each other they proved to be simultaneous, and on comparing the curves he had found them to coincide generally with great exactitude; for example, the curves described by the magnetic deflection at two points so far separated as China and Lisbon were absolutely identical. It was worth noticing that during the prevalence of sun spots the earth receives less heat than usual from the sun, and connecting this fact with Professor Hughes's new theory of magnetism, it is possible that we may soon be able to frame a consistent theory in explanation of the known phenomena.

A discussion followed in which several members took part.

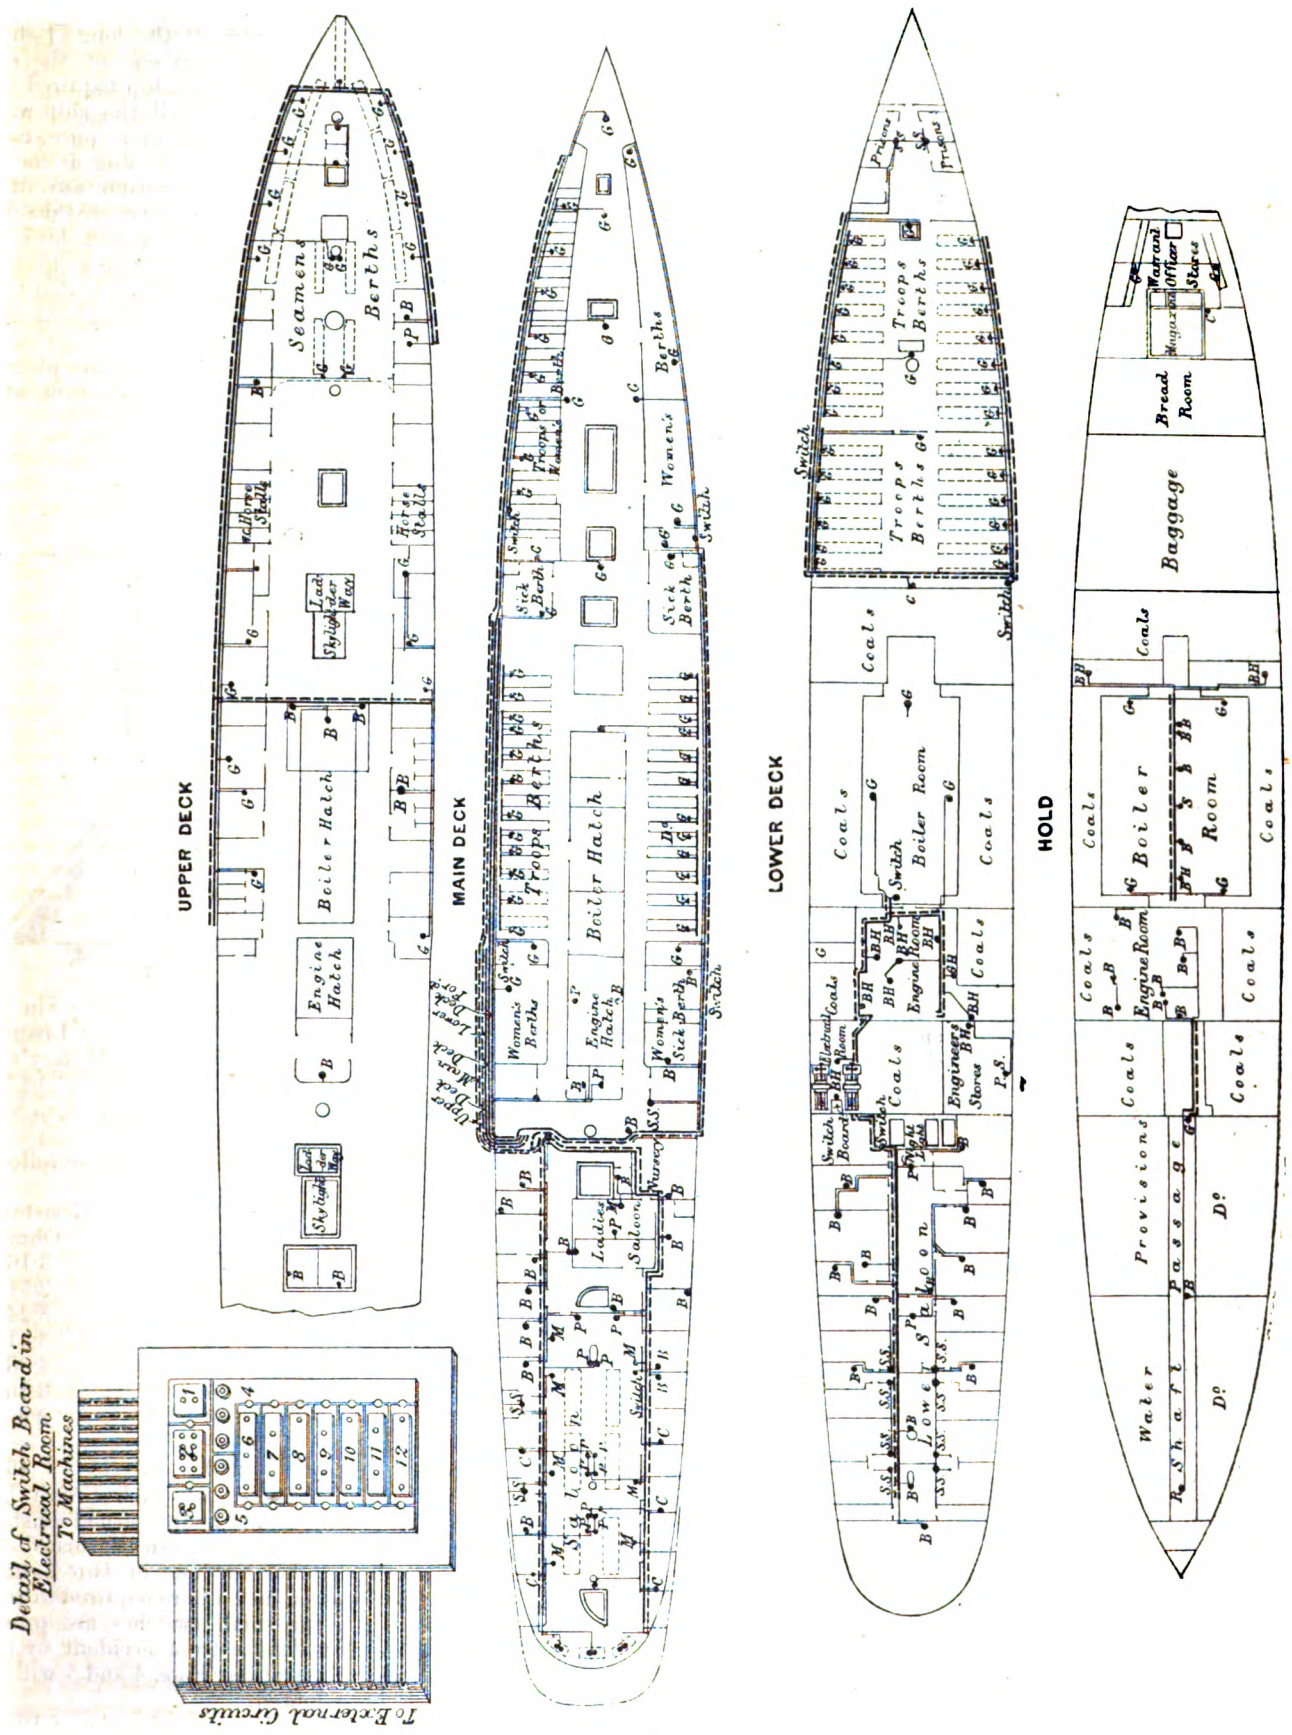
THE LIGHTING OF H.M.S. "HIMALAYA."

Since the days when the war ships of the Danes caused consternation among the inhabitants of the English coast, when such rulers as Alfred built vessels to meet the marauders upon the sea, England has reigned supreme as a maritime nation. We are, in fact, descendants of maritime races, and are proud of our ships. The more enlightened among the shipowners are always anxious to test new inventions that tend in any way to ameliorate the conditions of life on board ship. Hence the great companies owning passenger vessels tried the electric light almost as soon as the inventors themselves stated it to be at all practicable. We have often dwelt upon the adaptability of the



Digitized by Google

incandescent light for ships' use, and were glad to record the lead of private companies being followed by the Government. A short time since, *vide The Electrician*, Vol. X., No. 5, we briefly described the work of the Swan United Company carried out on board one of the Indian troopships —the "Himalaya." It does not come within our province to describe these magnificent vessels. They have often been described in the technical papers, but we trust soon to chronicle the extensive use of the electric light in all such ships. Readers of voyages and travels—and who has not read them—have often read of the sufferings from heat in trips through the Red Sea, and in other tropical seas, and not only those who suffer from sea sickness but almost every traveller will agree that, although it may be impossible to get rid of the heat, they are glad to find it possible to do away with the nauseous smell of the oil lamps, and to have in their place the purer, and at all events scentless, incandescent lamp.

The installation of the electric light on board the "Himalaya" has been carried out by the Swan Company, whose tender was accepted on October 23, the work being finished for the official trials on December 13th. The time was not long, and when it is considered that, owing to "speed trials" and other work, considerable delays arose, credit must be given for having thus early completed the installation. We are informed that every facility was given by the dockyard authorities at Devonport for pushing forward the work.

The lamps used are of two kinds—viz., 20 candle-power lamps, and 10 candle-power lamps. There are 171 of the former and 78 of the latter, giving a total of 249 lights. The 20 candle-power lamp, to give its normal light, requires a current of about 1·24 ampere, with an E.M.F. of 54 volts. These lamps are all arranged in multiple arc, but the 10 candle-power lamps are placed two in series and in multiple arc, two of the latter being equivalent to one of the former. The arrangements were carried out by Mr. J. F. Albright, of the Swan Company. The lamps have been distributed throughout the ship in the manner shown in the illustration on page 321. The lamps are arranged on seven circuits, all of which are controlled from a main switch-board, placed in the electrical room. A detailed sketch of the switch-board is shown at the upper left hand corner of the illustration. On reference to the sketch it will be seen that the lower part consists of seven long brass plates. Upon these are the names of the various parts of the ship, but in the sketch they are referred to by numbers 6, 7, 8, &c., for clearness. Thus:—

6 indicates plate on which name Upper Deck appears.
7 indicates plate on which name Forward Main Deck appears.
8 indicates plate on which name Aft Starboard Main Deck appears
9 indicates plate on which name Aft Port Main Deck appears.
10 indicates plate on which name Forward Lower Deck appears.
11 indicates plate on which name Aft Lower Deck appears.
12 indicates plate on which name Engine Room appears.
Nos. 1 and 3 indicate plate for machine returns.
No. 2 indicates plate for return leads.
No. 4 indicates plate for port machine.
No. 5 indicates plate for starboard machine.

The brass plates 6, 7, 8, &c., are divided from each other, and also from the two long ⌐-shaped brass plates, which, together with seven plates just mentioned, make up a complete rectangle. The lower part of the switch is separated by a division running right across the "board," from the upper or return part. The lower part forms the lead section, and it is, as will be seen, on this part that all the seven circuits are made or broken.

The six cables represented by six full lines at the top are fixed in the six terminals shown at the top of the "lead" section of the "board," three being for each machine. The four cables shown by four dotted lines, two for each machine, are fixed in the terminals on the two plates marked machine returns.

The seven cables shown in seven full lines go to the terminals on the seven plates named with the parts of the ship, the seven cables shown in the seven dotted lines go to the terminals or plate marked "return leads" which should be called "external returns."

To use the port machine insert the plug between the right hand "machine return" plate and the "return leads" plate, and then insert another plug between the long ⌐-shaped plate, marked "port machine," and any one of the seven named plates according to the part of the ship required to be lighted. When the seven plugs are in all the ship will be lighted, and if both machines are working at once, to use the starboard machine insert the second plug at the left-hand machine return plate, and then transfer any of the seven plugs from the port machine to the starboard machine.

The whole of the brass work is solidly screwed down to a strong backing of vulcanised fibre; this is set in a stout teak frame, supported by two wrought-iron brackets bolted to the bulkhead, arranged to set the board at an angle of about 30deg. with the bulkhead.

The grooved teak casing in which the cables are placed in the electrical room is brought up to and finished off at the switch-board.

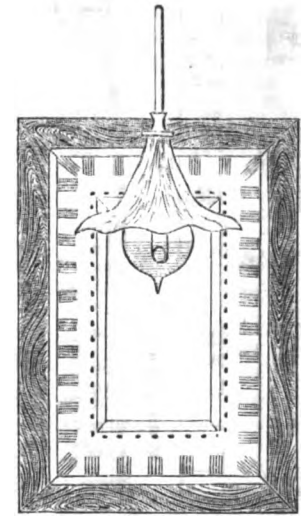


FIG. 1.

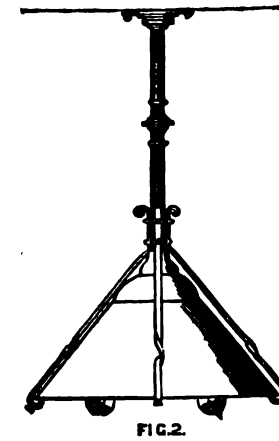

FIG. 2.

The over-all size of the brasses is about 13in. by 8in.; the switch was made by Messrs. J. J. Marr and Co., of Liverpool.

Throughout the ship in laying the wires Mr. Massey's rule of "leads to the left or lowest and returns to the right" has been observed as far as possible, it only having been necessary to break the rule once for a few yards.

As regards the resistance of various circuits, the following figures are roughly approximate:—

Circuits.	No. of Lamps = 20 C.-P.		Resistance Ohms.
Upper Deck	31	.....	3·16
Main Deck Forward	38	.....	2·51
Main Saloon Starboard	26	.....	3·24
Main Saloon Port	26	.....	3·41
Lower Deck Forward	23	.....	4·06
Lower Saloon	26	.....	3·48
Engine Room	40	.....	2·9
Combined Circuits	210	.....	·45

In addition to the main switch-board each circuit has a switch, so that, with the exception of lamps burned constantly day and night, the lamps of that circuit can be turned on or off, and further small switches for one or two lights are placed in all the cabins, and, in fact, where required to govern the lamps in detail. All the small switches are provided with lead cut outs, so that danger from accident by heavy currents is avoided. Our illustrations Figs. 4 and 5 will show the forms of the switches adopted.

The main leads are of Siemens Brothers' make of 19 wires of No. 16 B.W.G., heavily insulated with tape and india rubber. The branch wires are of a single No. 16 B.W.G. wire, with an equally high class insulation, specially made for ship work by the (Silvertown) Gutta Percha and India

Digitized by Google

Rubber Company. The leads and returns are laid in grooved wood casing, ½in. apart, the greatest care having been taken throughout the ship to avoid any possibility of short circuits

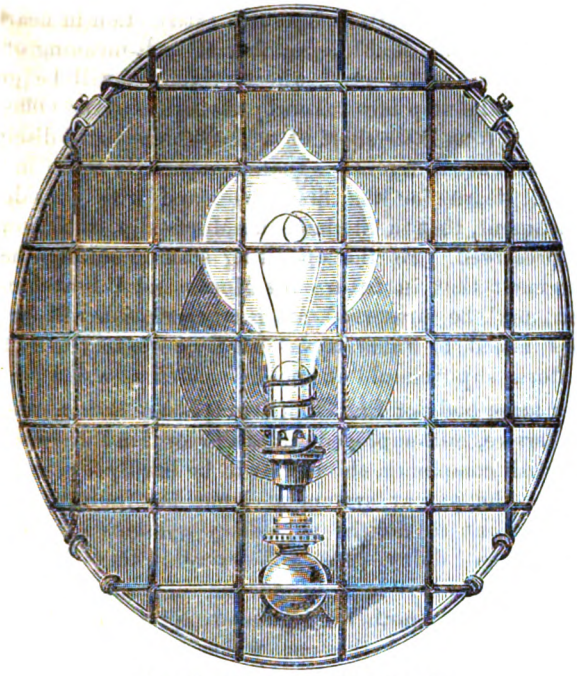

Fig. 3.—Lamp with Wire Guard.

or of metallic contact with the framework of the ship, lead cut outs being inserted at the junctions of all branch wires.

The fittings are of several kinds, of some of which we give

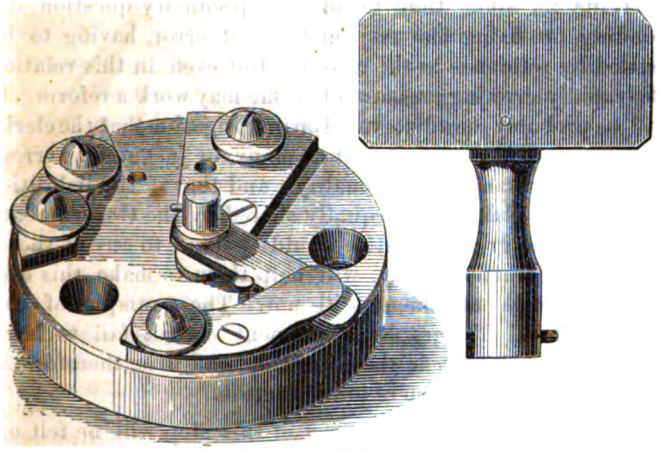

Fig. 4.—Switch.

illustrations; the greater part of them were supplied by Messrs. Faraday and Sons. Ornamental mirrors (Fig. 1) are used on the panels of the main saloon, the centre of

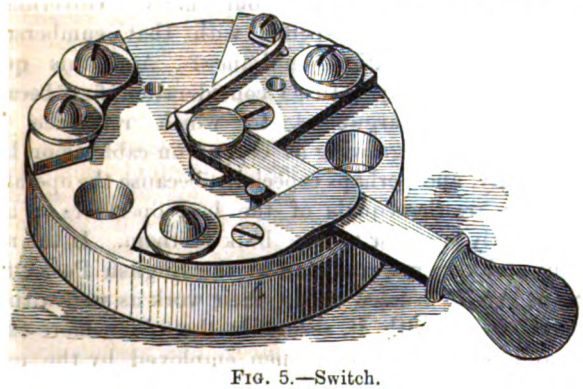

Fig. 5.—Switch.

which is lighted by plated brackets, while over the card tables aft are fixed three handsome double-light plated pendants (Fig. 2). The ordinary ship's bulkhead lanterns when possible have been adapted to suit the new lamps, and on all the troop decks or in exposed places a reflector with wire guard front (Fig. 3), specially designed for this ship, and suggested by Mr. Farquarhson, of the Admiralty, has been used. The remainder of the fittings are ordinary ship's brackets.

We understand that at the official inspection before alluded to the Admiralty experts expressed themselves well pleased with the result, both as to workmanship and illumination obtained. In reference to the latter, however, a few additions were suggested, which were promptly carried out, and subsequent experience has shown that in regard to the distribution and amount of light there is nothing further to be desired.

The electric room, as will be seen from the plan, is reached through the engine room, but is not a part of it, a portion of the coal bunkers having been given up for the room. The space provided, about 19ft. 2in. × 10ft. 6in. is ample for the duplicate set of engines and machines required under the contract.

The machines are of the Siemens alternate current type, with specially large exciters running at the same speed as the machine. The speed is about 640 revolutions per minute, when the maximum light is required, though in practice 610 revolutions are generally found sufficient even with all the lights in circuit.

The engines run continuously, are of the well-known Brotherhood type, with three cylinders, and are coupled direct to the machines. Engines and machine are both on one cast-iron bed-plate, which is placed on an 8in. teak bed, the whole being firmly bolted to the framework of the ship.

There are two separate services of steam pipes, one from the main boilers, and one from the auxiliary boiler, the exhaust steam being turned into the main condenser.

THE ACTION OF THE MICROPHONE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have watched with great interest the discussion going on in your journal for the last few weeks on the above subject, and I must say I am inclined to think Mr. Smillie is right in regard to the microphonic action of a Blake transmitter being due to the variation of the resistance of carbon under pressure, though at the same time I think that it is also partly due to the making of a better contact between the platinum stud and carbon button, due to the platinum point burying itself in the carbon button, and thereby causing an increase in the current owing to the resistance of the circuit being diminished.

With regard to "Loose Contact's" letter in your issue of 27th ult., he says Mr. Smillie, in his second letter, abandons the compression theory. Now, on reading that, I turned up *The Electrician* containing the letter referred to, and read it over, and I must say I fail to see how "Loose Contact" comes to that conclusion. He denies saying that a brass button would speak as well as a carbon one. Well, he certainly did not put it in plain English, but I am at a loss to know what other construction could be put on the sentence reading thus:—"Then let him blow upon and tickle his diaphragm as before, and inform you, Mr. Editor, whether he thinks the diminished resistance which he will observe *is still due to the compression of the carbon button.*"

He also says that the fact of Mr. Smillie getting the brass button to speak proves his case to the hilt. It certainly would have done so if it had spoken well, but Mr. Smillie says he got the brass button to speak, and that was all. It certainly looks very like as if the defect in the speaking was due to the fact that the brass is practically incompressible.

With regard to Mr. Smillie not getting the same galvanometric action as "Loose Contact" predicted, I think he is rather premature in condemning Mr. Smillie's galvanometer until he knows whether Mr. Smillie used the same one for his experiments with the carbon and brass buttons, as, if he did, and it was not a good one, it would be equally bad for both tests.—Yours, &c.,

John Hill.

TO CORRESPONDENTS.

C. N. R...ll.—At present there is a lull in electric light work, but no doubt, as soon as the provisional orders, licenses, &c., are settled, there will be a strong demand for competent men. Why not write to some of the companies?

J. M...e.—We shall make a point of calling on you at the Palace, and seeing all you have to show us, at the earliest opportunity.

X.—Our space is far too small for the demands we have upon it. Business men, shareholders, &c., ask for full reports of all meetings. It is, they say, important there should be no break in the continuity of the reports. Practical men tell us we give too much science, that formulæ are no doubt good in their way, but indigestible to the ordinary reader—while the scientific thinker wants more pure science, and so on. On the whole, however, our friends are very lenient. Still, we must hesitate before giving a list of a column or half a column such as you desire. The attention of writers shall be directed to your remarks.

C. B. C.—Write to Mr. A. J. Frost, the librarian, who will give you all the information you require.

THE MORSE SLIP.

The announcement we made in our last issue that the postal telegraph authorities of this country had discontinued the practice of preserving Morse slip will be received with surprise in many quarters, but with satisfaction in nearly all. There are still, no doubt, a number of well-meaning officers, both at home and abroad, whose prejudices will be greatly shocked at the step now taken by the British Post Office, and will regard it as little short of a deathblow to all discipline. Others who are differently situated, especially those in America, will learn for the first time, and with considerable astonishment, that in England the Morse slip, until now, has been preserved. To the operating staff generally the announcement that in future the Morse and Wheatstone slip "need not" be preserved after transcription will be good tidings indeed, to which it was hardly necessary to add that said Morse slip "should at once be treated as waste paper."

To a large body of English telegraphists, not in the Post Office service, but employed on cables or land lines worked by English companies, the news will be hardly less welcome; for what the parent system at home has found it possible and expedient to do, the subsidiary systems cannot long refrain from doing. At all events, they have now one argument the less in favour of adhering to the old practice. Another argument, probably the most effectual of all, and the one which has probably proved conclusive for the Inland authorities, namely, the pressure of traffic, will in due time convince the rest of the telegraphic world as well. On international lines, that is to say, lines worked direct between nation and nation, the preservation of slips, either Morse, Wheatstone, or Hughes, may continue for some time to come—a pecuniary question, depending on fixing the responsibility of error, having to be settled by reference to the record. But even in this relation the rapidly-growing pressure of traffic may work a reform. It will be probably soon discovered on investigation that the clerks of one nationality commit just as many, or just as few, errors as do those of another nationality; and that if the liabilities in respect to claims were equally shared by the Governments concerned no great injustice would be done to any of them. Increase of traffic, we say, will help them to make this discovery, though argument will not. The example of the British Postal Telegraph Department cannot fail to have some effect, however, in that direction, and it is, therefore, a subject of more than mere local interest.

For similar reasons the effect of this step will be felt on lines that are not international in the sense above alluded to—that is to say, on lines worked at both ends by the servants of one administration. The question will arise why should we any longer preserve slip, Morse or Syphon, or any kind whatsoever, when our native Government has seen its way to dispense with that cumbersome and in every way vexatious nuisance? And this question will be less easily refused consideration, first because the same practical argument to which reference has already been made is growing as cogent on cable as on land lines; secondly, and perhaps especially, because the operators on cable lines are the equals of the best operators on land lines, and vastly superior to the bulk of them. If the miscellaneous and very unequal staff of the English Post Office Telegraphs can be trusted to do their work as well without the slip check as with it, assuredly the older, more experienced, and generally superior men employed by the cable companies may be so trusted.

Of course we are aware there is another consideration in the background besides the good faith or the skill of the

Digitized by Google

operator. The class of messages dealt with by the last-named *employés* is far more costly, and the consequences of error or carelessness are relatively more serious than those of any inland system of telegraphs. As a fact, however, the inland system does deal largely with this class of messages in its terminal stages, and the announcement we are discussing makes no exception in favour of foreign, cypher, or cable telegrams. The slips of all alike are to be treated at once as waste paper. Moreover, it is rather illogical and contrary to experience to suppose that difficult and expensive telegrams will be signalled with less conscientious exactness than are the cheap and easy messages of a local system. The exact contrary is the fact, and it is not in the least affected by the preservation or non-preservation of the slip. For many years after the introduction of telegraphy the charge for an inland telegram was as high as that for a cablegram is now, and the instruments were non-recording. Possibly the proportion of errors diminished on the substitution of recording apparatus—possibly, though not certainly; and in any case the improvement, if any, was due more to the new instrument than to the terror its record was supposed to have inspired.

It comes to this, in fact, that the slip has been preserved simply to humour administrative martinets. Errors can be traced to the miscreants who commit them, and punishment awarded. This is enough for the disciplinarian, and he is happy. True, they can as easily be traced, and almost as certainly, without any slip at all, but punishment is not so confidently inflicted, nor so often; therefore the slip has survived until now, and will, we suppose, survive in some places for a long while yet to come in order that fines may be inflicted. And this, notwithstanding the obvious injustice and impolicy of preserving the slip for mere detective and tell-tale purposes—injustice, because it inflicts the heaviest penalties on the clerks who do most work; impolicy, because its tendency is to decrease the speed of working, and the zeal of the working staff.

THE TELEPHONE CASE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It may interest your readers, apart from the detailed report which you furnish elsewhere, to draw attention to some of the salient points in this remarkable case.

The description in the evidence of Sir W. Thomson of the final step in Bell's invention is of no less popular than scientific interest. In the earlier form of Bell's instrument—which spoke at Philadelphia, but was dumb before the British Association at Glasgow in 1876—the reproduction of sound depended upon the vibrations of a thin plate or tongue of metal attached at a single point to the box containing the magnet. Every one at the time, including Sir W. Thomson, supposed that on the freedom of vibration of this plate or tongue the whole action depended. Mr. Bell's final success was achieved by using a substantial metal plate, firmly set down on the top of the box; and the surprise which this created, in 1876, amongst scientific men seems only equalled by the difficulty, in 1883, in conceiving that any one would attempt to use the Philadelphia or Glasgow instrument without holding down the lid. No less remarkable were the experiments of Professor Silvanus Thompson before the Court of Appeal, showing how, in 1883, not only the Glasgow form of Bell's instrument, but an instrument constructed from the much earlier description and drawings of Reis, could be made to speak articulately and clearly. It was no wonder that after these experiments the Court required a long and powerful argument from the side of the respondents to enable them to appreciate the position of the scientific world in 1876, before the marvellous stride in the science of acoustics which followed upon the achievement of the articulate-speaking telephone.

More interesting to the lawyer is the treatment—and, perhaps, extension—by the judges of the Court of Appeal of the doctrine conventionally described as the *benevolent* or *benignant* doctrine of construction or interpretation. The specification claimed, according to the more obvious reading of it, the production of undulating currents. In the most general sense of the expression this claim was not new; but if read as a claim to the production of undulatory currents so as to reproduce articulate speech in the manner described, it was new and good. The Court held the claim *capable* of this latter interpretation, and gave the inventor the benefit, so as to make the patent valid.

The decision upon this point is all the more weighty, as the language of the Lords Justices is carefully guarded against allowing the claim in a specification to be made a mere trap to the public. The judgment of Lord Justice Bowen is particularly clear and explicit. He described the decision as being merely the application of the ordinary rules of construction to a very special subject matter; but he suggests a principle which may prove a new point of departure in Patent Law, namely, the *interpretation from the point of view of the honest inventor*.

If it had been avowed that there is one rule of construction for the specification of the honest inventor and another for that of the patent-monger, who, on the minimum of inventive achievement, seeks to appropriate the maximum out of the field of invention, the doctrine, if morally wholesome, might have seemed legally questionable. The importance of the lucid exposition of Lord Justice Bowen is to show that a principle tending in this direction within carefully guarded limits, is not less sound in law than desirable on grounds of utility. The legal construction of a document is simply its meaning as ascertainable from the point of view of the parties to it. To interpret a will, you have to look at the surrounding circumstances of the testator. To interpret a contract you must look at the surrounding circumstances of the parties, and ascertain the meaning of the language of the document from their common point of view. From this point of view it is ascertained, for instance, whether a trade usage is or is not to be introduced into the contract. Upon the same principle the grant of a patent as described in the specification is to be ascertained from the point of view of the inventor—not forgetting, of course, that he is addressing a public composed of persons having skill in the subject matter. And—what is the gist of the decision of the Court of Appeal—if, upon the evidence of the surrounding circumstances, it is shown that he is an honest inventor seeking to give the public the benefit of a new and useful machine, his claim, if *capable* of a construction that will make the grant good, is to be construed accordingly, although it is capable of another and even an easier construction which would make it bad.

What gives special importance to the decision upon this point is that it only restates and formulates what is essentially the judgment of the House of Lords in the British Dynamite Company *v.* Krebs (April 7, 1879), a decision briefly reported only in the weekly notes of cases in the *Law Journal*, and which does not seem at the time to have attracted the attention due to the importance of the doctrine involved in it.

There is one other point suggested and disposed of during the argument of the telephone case before the Court of Appeal, which it may be the more useful to note here, as it was not again referred to in the judgment. At one stage of the reply the well-nigh assured success of the respondent seemed for a moment imperilled by the suggestion, that *one* of the claims as read with the disclaimer was enlarged beyond the original claim. It was, however, pointed out by Lord Justice Lindley that, although the *particular* claim was enlarged, this enlarged claim was still within the scope of the original grant *as a whole*. And on the well-known principle that in considering the validity of the grant you must look at the whole of what is claimed, and not at the claims taken separately, this was clearly sufficient to support the patent as disclaimed.—Yours, &c., R. C.

Lincoln's Inn, Feb. 12, 1883.

STUDENTS' COLUMNS.

CITY AND GUILDS EXAMINATIONS.

[*These answers are intended to guide, to give information and references, to put the student in the way of getting information, and* NOT *to give the exact answers that should be written in an examination.*]

The solutions in this number are alternative solutions to some of the "*Honours*" questions in the paper hitherto considered, by E. C. RIMINGTON, Esq. (School of Electrical Engineering), 12, Princes-street, Regent-street.

11. This question is the same as No. 8 of the pass examination, where the answer will be found. (*Electrician*, Dec. 2.)

12. What is the principal of a photometer? What form of photometer is most suited for use with strong electric lights? About how much per cent. are English "standard candles" found to differ? Describe Vernon Harcourt's light standard. What is your experience of the relative penetrating power of gas and the electric light in a fog? Explain what you think is the cause of this result, and in what way you would propose to increase the penetrating power of the electric light.

Ans. The first two parts of this question were answered in No. 11 of the pass examination.

English standard candles are found to differ from about 3 to 4 per cent., that is to say, even in the same packet of candles one may be found to average about 118 grains of spermaceti per hour, while another may burn 121 or 122 grains in the same time. For very accurate working the candles are weighed at the beginning and at the end of the experiment.

Vernon Harcourt's standard, which is exceedingly exact and trustworthy, is an air gas flame 2½in. high, proceeding from a burner with a ¼in. orifice. The gas is burned at a definite rate, and consists of a definite mixture of air and the vapour of light petroleum.

In a yellow London fog the rays from gas have relatively a far greater power of penetration than those coming from an electric arc lamp; this is due to the fact that the gas contains far more red and yellow rays than the arc light, which, is on the other hand, far richer than the gas in the blue and violet rays.

The yellow colour of the fog absorbs a large quantity of the blue and violet rays, while it allows the red and yellow to pass with comparatively small loss.

The penetrating power of the electric light might be increased by mixing some substance with the carbon that would give the arc a more yellow tint.

The penetrating power of incandescent lamps in a fog is much the same as that of gas.

13. Describe in detail and give sketches of the instruments employed for measuring large currents and large electromotive forces—first, when the currents and electromotive forces are continuous; second, when they are rapidly reversed. Compare the relative advantages and disadvantages of the various forms of instruments.

Ans. The instruments principally employed for measuring large currents are Ayrton and Perry's ammeter and Siemens's dynamometer, the latter of which is applicable for either continuous or alternating currents. Both of these were described in answer to Question 12 of the pass examination. For measuring large electromotive forces Ayrton and Perry's voltmeter and Siemens's voltmeter are, perhaps, the best known and most generally employed. The former is in external form the same as the ammeter; it is, however, wound with a high resistance, and in the commutator form is employed with the coils in multiple arc for low E.M.F.'s and for calibrating, and in series for high E.M.F.'s, when it is ten times less sensitive. Its terminals are simply connected to the two points between which the difference of potential is required.

The principal advantages of Ayrton and Perry's instruments are that they are perfectly dead beat, the pointer marking the division that gives the current or E.M.F. at the moment of observation, and that they will work in any position; whilst in Siemens's instruments the pointer at the top of the dial has to be altered until the torsion of the spring exactly balances the attraction and repulsion of the coils. This is exceedingly inconvenient in measuring a rapidly-fluctuating current or E.M.F. Another disadvantage is that they must be perfectly level.

The advantage of Siemens's instruments over Ayrton and Perry's is that they can be employed with alternating currents, because the directions of the currents in the two coils are relatively the same to one another at whichever terminal of the instrument the current enters. Ayrton and Perry's, on the other hand, show in which direction a continuous current is flowing, being so wound that the needle points to the terminal at the highest potential.

14. How is the current flowing through any circuit, and the electromotive force maintained between its ends, connected with the horse-power expended in the circuit? Describe an electric-power meter for measuring from one observation the horse-power electrically expended in a circuit. Give a full account, with sketches, of the experiments you would make to measure the number of candles produced per horse-power expended in an electric lamp. Give the results of any experiments that have been made, showing how this efficiency of a lamp varies with the work electrically done in it.

Ans. The product of the current flowing in an electric circuit, and the E.M.F. maintained between its ends, divided by the constant 746, is equal to the horse-power electrically expended in that circuit, either in doing mechanical work or in producing heat.

$$\frac{C\,E}{746} = W \text{ in horse-power,}$$

as

$$C = \frac{E}{R},$$

$$\frac{C\,E}{746} = \frac{E^2}{746\,R} = \frac{C^2 R}{746} = W \text{ in horse-power.}$$

Messrs. Ayrton and Perry have invented an instrument called the "electric-power meter" for measuring at one observation the horse-power expended electrically in any circuit. This instrument consists of a coil of very fine wire, having a high resistance, wound on a long thin bobbin, and capable of moving about an axis parallel to the length of the bobbin. This coil is capable of moving inside another fixed coil of very thick wire, or of ten thick wires arranged so that they are able to be joined up either in multiple arc or in series by means of a commutator similar to that employed in the ammeter. The moving coil is either hung from a bifilar suspension, or arranged with a wheel and pinion and two fine spiral springs, one or both of which latter can be employed, and so two very different grades of sensibility given to the instrument. The rack and pinion arrangement magnifies the deflection of the fine coil as shown by the pointer ten times.

The thick coil is placed in the main circuit, and the fine coil is employed as a shunt on that part of the circuit in which the horse-power is desired to be measured. The thick coil thus measures the main current, while the fine coil measures the difference of potential between the two points, to which it is connected. The deflection, therefore, of the latter measures the product of the current and the E.M.F. or C.E.

By turning the commutator so as to place the ten thick wires in series the sensibility of the intrument is increased ten times, either for the means of calibration or to measure the power expended in a small part of the circuit, such as in one incandescent lamp. To measure the candle-power produced per horse-power electrically expended in an electric lamp, the current passing through the lamp is found by means of an ammeter or other instrument for measuring current, while the difference of potentials at the terminals of the lamp is measured by a voltmeter, or both observations may be obtained at once by use of the instrument just described. If, however, the ammeter and voltmeter are employed, the current in amperes is multiplied by the number of volts indicated by the voltmeter, and the product divided by 746. Simultaneously with the above operations the candle-power of the lamp is obtained by means of a photometer. Then if a be the number of candles indicated, and b the horse-power electrically absorbed in the lamp, $\frac{a}{b}$ is the number of candles obtained per horse-power expended in the lamp.

ERRATUM.—In the answer to Question 3 of pass examination the word field-magnets occurs instead of armature, through an inadvertent slip in writing.

ELECTRIC LIGHTING TO THE RESCUE.—Owing to the fearful floods at Cincinnati, U.S.A., the gas supply has been cut off for some days. As Mrs. Langtry was in this city a few days since to fulfil an engagement at the theatre there, it was found necessary to call in the aid of electric lights for the illumination of the theatre for the occasion.

CANTOR LECTURES.*

DYNAMO-ELECTRIC MACHINERY.

BY PROFESSOR SILVANUS P. THOMPSON, B.A., D.SC., M.S.T.E.

Lecture III. (*continued*).—*The Dynamo as a Motor.*

(CONTINUED FROM PAGE 307.)

Jacobi's law concerning the maximum work of an electric motor supplied with currents from a source of given electromotive force is the following:—The mechanical work given out by a motor is a maximum when the motor is geared to run at such a speed that the current is reduced to half the strength that it would have if the motor was stopped. This, of course, implies that the counter-electromotive force of the motor is equal to half the electromotive force furnished by the battery or generator. Now, under these circumstances, only half the energy furnished by the external source is utilised, the other half being wasted in heating the circuit. If Jacobi's law were indeed the law of efficiency, no motor, however perfect in itself, could convert more than 50 per cent. of the electric energy supplied to it into actual work. Now Siemens showed,† some years ago, that a dynamo can be, in practice, so used as to give out more than 50 per cent. of the energy of the current. It can, in fact, work more efficiently if it be not expected to do its work so quickly. Dr. Siemens, to whom we owe the honour of having first shown us the true physical signification of the mathematical expressions which, until then, had been regarded as mere abstractions, has, in fact proved that if the motor be arranged so as to do its work at less than the maximum rate, by being geared so as to do much less work per revolution, but yet so as to run at a higher speed, it will be more efficient—that is to say, though it does less work, there will also be still less electric energy expended, and the ratio of the useful work done to the energy expended, will be nearer unity than before.

The algebraic reason is as follows:—If E be the electromotive force of the generator when the motor is at rest, and c be the current which flows at any time, the electric energy, W, expended in unit time, will be (as expressed in watts) given by the equation.

$$W = Ec = E\frac{(E-e)}{R} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Now, when the motor is running, part of this electric energy is being spent in doing work, and the remainder is wasting itself in heating the wires of the circuit. We have already used the symbol w for the useful work (per second) done by the motor. All the energy which is not thus utilised is wasted in heating the resistances. Let the symbol H represent this heat. Its mechanical value will be H J, where J stands for Joule's equivalent. Taen clearly we shall have

$$W = w + H J.$$

But, by Joule's law, the heat-waste of the current, whose strength is c running through resistance R, is expressed by the equation

$$H J = c^2 R.$$

Substituting this value above, we get

$$W = w + c^2 R, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

which we may also write

$$w = W - c^2 R.$$

But by equation (1) $W = Ec$, whence

$$w = Ec - c^2 R, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

and, writing for c its value, $\frac{E-c}{R}$, we get:

$$w = \frac{\left(E-e\right)\left(E-\left\{E-e\right\}\right)}{R},$$

$$\text{or } w = e\frac{E-e}{R} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

Comparing equation (5) with equation (1), we get the following:—

$$\frac{w}{W} = \frac{e\,(E-e)}{E\,(E-e)}$$

or, finally—

$$\frac{w}{W} = \frac{e}{E}.$$

This is, in fact, the mathematical law of efficiency, so long misunderstood until Siemens showed its significance. We may appropriately call it the law of Siemens. Here the ratio $\frac{w}{W}$ is the measure of the efficiency of the motor, and the equation shows that we may make this efficiency as nearly equal to unity as we please, by letting the motor run so fast that e is very nearly equal to E; which is the true law of efficiency of a perfect motor supplied with electric energy, under the condition of constant external electromotive force.

Now go back to equation (3), which is:—

$$w = Ec - c^2 R.$$

In order to find what value of c will give us the maximum value for w (which is the work done by the motor in unit time) we must take the differential coefficient and equate it to zero.

$$\frac{dw}{dc} = E - 2cR = o,$$

whence we have

$$c = \tfrac{1}{2}\frac{E}{R}.$$

But, by Ohm's law, $\frac{E}{R}$ is the value of the current when the motor stands still. So we see at once that, to get maximum work per second out of our motor, the motor must run at such a speed as to bring down the current to half the value which it would have if the motor were at rest. In fact, we here prove the law of Jacobi for the maximum rate of doing work. But here since—

$$c = \frac{E-e}{R} = \tfrac{1}{2}\frac{E}{R},$$

it follows that

$$E - e = \tfrac{1}{2}E;$$

or

$$\frac{e}{E} = \tfrac{1}{2},$$

whence it follows also that

$$\frac{w}{W} = \tfrac{1}{2}.$$

That is to say, the efficiency is but 50 per cent. when the motor does its work at the maximum rate.*

Now, though several graphic constructions have been suggested to convey these facts to the eye, none have hitherto been, to my mind, quite satisfactory. I have, therefore, worked out a new construction, which enables me, in one diagram, to exhibit graphically both Jacobi's law of maximum rate of working, and Siemens's law of efficiency.

Let the vertical line A B (Fig. 34) represent the electromotive force E of the electric supply. On A B construct a square, A B C D, of which let the diagonal B D be drawn. Now measure out from the point B along the line B A the counter-electromotive force e of the motor. The length of this quantity will increase as the velocity of the motor increases. Let e attain the value B F. Let us inquire what the actual current will be, and

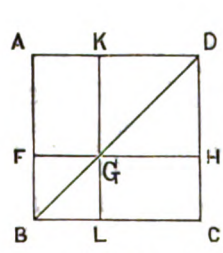

FIG. 34.

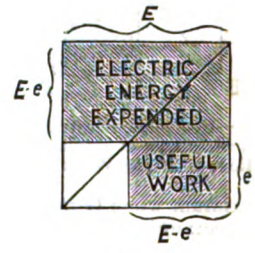

FIG. 35.

* Reprinted from the *Journal of the Society of Arts.*

† The matter was also very well and clearly put by Prof. W. E. Ayrton, in his lecture on "Electric Transmission of Power," before the British Association in Sheffield, in 1870.

* It may be worth while to recall a precisely parallel case that occurs in calculating the currents from a voltaic battery. Every one is familiar with the rule for grouping a battery which consists of a given number of cells, that they will yield a maximum current through a given external resistance when so grouped that the internal resistance of the battery shall, as nearly as possible, equal the external resistance. But this rule, which is true for maximum current (and, therefore, for maximum rate of using up the zincs of one's battery) is not the case of greatest economy. For if external and internal resistance are equal, half the energy of the current will be wasted in heat in the cells, and half only will be available in the external circuit. If we want to get the greatest economy, we should group our cells so as to have an internal resistance much less than the external. We shall not get so strong a current, it is true; and we shall use up our zincs more slowly; but a far greater proportion of the energy will be expended usefully, and a far less proportion will be wasted in heating the battery cells. The maximum economy will, of course, be got by making the external resistance infinitely great as compared with the internal resistance. Then all the energy of the current will be utilised in the external circuit, and none wasted in the battery. But it would take an infinitely long time to get through a finite amount of work in this extreme. The same kind of reasoning is strictly applicable to dynamos used as generators, the resistance of the rotating part of the circuit being the counterpart to the internal resistance of the battery cells. For good economy the resistance of the armature should be very low as compared with that of the external circuit. Mr. Edison seems to have been struck by this point, as his endeavours to reduce the resistance of his armature coils to the utmost limit of possibility show.

Digitized by Google

what the energy of it; also what the work done by the motor is. First complete the construction as follows:—Through F draw F G H, parallel to B C, and through G draw K G L, parallel to A B. Then the actual electromotive force at work in the machine, and producing the current, is $E - e$, which may be represented by any one of the lines A F, K G, G H, or L C. Now the electric energy expended per second is—

$$\frac{E(E-e)}{R}$$

and the work done by the motor is—

$$\frac{e(E-e)}{R}$$

Since R is a constant, the relative values of the two may be written respectively—

$$E(E-e)$$

and

$$e(E-e).$$

Now

$$\text{area A F H D} = E(E-e),$$

and

$$\text{area G L C H} = e\,(E-e).$$

The ratio of these two areas on the diagram is the efficiency of the motor.

Let us turn to Fig. 35, in which these areas are shaded. This figure represents a case where the motor is too heavily loaded, and can turn only very slowly, so that the counter electromotive force e is very small compared with E. Here the area, which represents the energy expended, is very large; while that which represents useful work realised in the motor is very small. The efficiency is obviously very low. Two-thirds or more of the energy is being wasted in heat.

Next, let us turn our attention to the smaller area, G L C H. Obviously, the value of this area will depend upon the position of the point F; for if F is very near B, the area will be very small. If F moves upward, the area, G C L H, will have a value that increases up to a certain point, and then diminishes again; for if F be taken very near A (that is, if e be very nearly equal to E), the area, G L C H, will become again a very narrow strip. Of all the possible cases, the area of this rectangle will

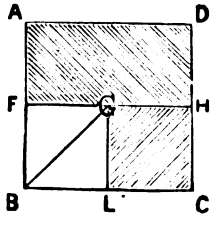

FIG. 36.—Geometric Illustrations of Jacobi's Law of Maximum Rate of Doing Work.

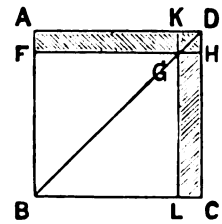

FIG. 37.—Geometric Illustration of Siemens's Law of Efficiency.

be a maximum when G is midway between B and D; for of all possible rectangles that can be inscribed in the triangle, B C D, that rectange which is a true square will have the greatest value, as drawn in Fig. 36. But if G is midway between B and D, the rectangle, G L C H, will be exactly half the area of the upper rectangle, A F H D; which is, in fact, Jacobi's law of the efficiency of a motor doing its work at its greatest possible rate. Also F will be halfway between B and A, which signifies that $e = \frac{1}{2}E$.

Again, consider these two rectangles when the point G moves indefinitely near to D (Fig. 37). We know, from Euclid's "Second Book," familiar from our school-days, that the rectangle, G L C H, is equal to the rectangle, A F G K. The area (square), K G H D, which is the excess of A F H D, over A F G K, must, therefore, represent that part of the electric energy which is wasted in heating the resistance of the motor and circuit. In Fig. 35, this corner square, which stands for the heat waste, was enormous. In Fig. 36 it was exactly half the energy. In Fig. 37 it is only about one-eighth. Clearly, we may make the heat-waste as small as we please, if only we will take the point F very near to A. The efficiency will be a maximum when the heat-waste is a minimum. The ratio of the areas, G L C H and A F H D, which represents the efficiency, can only become equal to unity when the square, K G H D, becomes indefinitely small; that is, when the motor runs so fast that its counter electromotive force, e, differs from E by an indefinitely small quantity only. Further, it is clear that if our diagram is to represent any given efficiency—for example, an efficiency of 90 per cent., then the point, G, must be taken so that the area G L C H = 9-10ths of the area A F H D; or G must be 9-10ths of the whole distance along B D. This involves that e shall be equal to 9-10ths of E, or that the motor shall run so fast as to reduce the current to 1-10th of what it would be if the motor were standing still. Thus we verify, geometrically, Siemens's law of efficiency.*

In all the preceding discussion I have supposed that the motor is to be worked with a supply of current furnished at a fixed electromotive force. It is not only convenient, but I believe wise, to make such a condition the basis of the argument, because this is, probably, the condition under which electric power will, in the not very distant future, be distributed over large areas. It would be absurd, in the present stage of electro-technical science, to deal with such a question as the construction and use of motors, without taking into account the practical conditions under which they will be used. It is true that the condition of having a constant fixed electromotive force is not the only condition of supply; for, as we have seen in preceding lectures, a generator or system of generators may be worked so as to yield a constant current. And it would be quite possible to formulate a set of rules for the efficiency and maximum duty of motors under this condition. But this method of distributing electric power is far less likely to be of importance in the near future than the system of distribution with constant electromotive force; though for the case of transmission of power to an isolated station the case becomes of importance. One simple problem connected with this case is worthy of mention. Suppose that one is desirous of working a motor so as to do work at the rate of a specified number of horse-power, and that the wire available to bring the current cannot safely stand more than a certain current, without being in danger of becoming heated unduly. It might be desirable to know what electromotive force such a motor ought to be capable of giving back, and what electromotive force must be applied at the transmitting end of the wire. Let N stand for the number of horse-power to be transmitted, and c for the maximum strength of current that the wire will stand (expressed in amperes). Then, by the known rule for the work of a current, since

$$\frac{ec}{746} = N,$$

$$e = \frac{746\,N}{c}$$

gives the condition as to what electromotive force the machine must be capable of giving when run at the speed it is eventually to run at as a motor. Moreover, the primary electromotive force, E, must be such that

$$\frac{E-e}{\Sigma R} = c,$$

where ΣR is the sum of all the resistances in the circuit. Whence

$$E = e + c\Sigma R,$$

which is the required condition.

Another problem in the application of motors to transmission of power, which vitally affects their construction, is the determination of the relation of the heat-waste to the electromotive force at which the current is supplied to the motor.

If, as before, ΣR stands for the sum of all the resistances in the circuit, then, by Joule's law, the heat waste is (in mechanical measure)

$$HJ = C^2\Sigma R.$$

And, since $c = \frac{E-e}{\Sigma R}$, we may write the heat-waste as

$$HJ = \frac{(E-e)^2}{\Sigma R}.$$

Now suppose that, without changing the resistances of the circuit, we can increase E, and also increase e, while keeping $E - e$ the same as before, it is clear that the heat loss will be precisely the same as before. But how about the work done? Let the two new values be respectively $\acute{E}$ and $\acute{e}$. Then the electric energy expended is

$$\acute{W} = \frac{\acute{E}(\acute{E}-\acute{e})}{\Sigma R},$$

and the useful work done is—

$$\acute{w} = \frac{\acute{e}(\acute{E}-\acute{e})}{\Sigma R}.$$

That is to say, with the no greater loss in heating, more energy

* We have all along supposed the motor to be a "perfect" one, that is to say, one which gave out as available mechanical work all the electric work it took from the supply of energy of the current. No motor does this, because of friction, &c. But it is easy to adapt the construction to the case. Suppose when working the motor as a generator, so as to give an electromotive force, e, we found that it was capable of converting 80 per cent. of mechanical energy into electrical energy, then we may put down the efficiency of the motor, *per se*, under the given conditions at 80 per cent. All we have then to do is to take an area 8-10ths of the size of the area G L C H (or cut off 1-5th of G L C H), and this will really represent the available mechanical work of the motor.

Digitized by Google

is transmitted, and more work done. Also the efficiency is greater, for

$$\frac{w}{W} = \frac{e}{E},$$

and this ratio is more nearly equal to unity than $\frac{e}{E}$, because both E and e have received an increment arithmetically equal. Clearly, then, it is an economy to work at high electromotive force. The importance of this matter, first pointed out by Siemens, and later by Marcel Deprez, cannot be over-rated. But how shall we obtain this higher electromotive force? One very simple expedient is that of driving both the generator and motor at higher speeds. Another way is to wind the armatures of both machines with many coils of wire having many turns. This expedient has, however, the effect of putting great resistances into the circuit. This circumstance may, nevertheless, be no great drawback, if there is already a great resistance in the circuit—as, for example, the resistance of many miles of wire through which the power is to be transmitted, in this case, doubling the electromotive force will not double the resistance. Even in the case where the line resistance is insignificant, an economy is effected by raising the electromotive force. For, as may be deduced from the equations, when E—e is kept constant, the effect of doubling the electromotive force is to double the efficiency, when the resistance of the line is very small as compared with that of the machines, and to quadruple it when the resistance of the line is very great as compared with that of the machines. It is, in fact, worth while to put up with the extra resistance, which we cannot avoid, if we try to secure high electromotive force by the use of coils of fine wire of many turns. It is true that the useful effect falls off, *cæteris paribus*, as the resistance increases; but this is much more than counterbalanced by the fact that the useful effect increases in proportion to the square of the electromotive force.

In the recent attempt of M. Marcel Deprez to realise these conditions, in the transmission of power from Miesbach to Munich, through a double line of telegraph wire, over a distance of thirty-four miles, very high electromotive forces were actually employed. The machines were two ordinary Gramme dynamos, similar to one another, but their usual low resistance coils had been replaced by coils of very fine wire. The resistance of each machine was consequently 470 ohms, whilst that of the line was 950 ohms.* The velocity of the generator was 2,100 revolutions per minute; that of the motor, 1,400. The difference of potential at the terminals of the generator was 2,400 volts; at that of the motor, 1,600 volts. According to Professor von Beetz, the President of the Munich Exhibition, where the trial was made, the mechanical efficiency was found to be 32 per cent. M. Deprez has given the rule that the efficiency $\frac{w}{W}$ is obtained, in the case where two identical machines are employed, by comparing the two velocities at the two stations. Or

$$\frac{w}{W} = \frac{n}{N}$$

where N is the speed of the generator, n that of the motor. There is, however, the objection to this formula, that the electromotive forces are not proportional to the speeds, unless the magnetic fields of the two machines are also equally intense, and the current running through each machine the same. This is not the case if there is leakage along the line. Moreover, when there are resistances in the line, the ratio of the two electromotive forces of the machines is not the same as the ratio of the two differences of potentials, as measured between the terminals of the machines.

I now turn back from these somewhat abstract questions to consider, by the light we have derived already, some points in the design and construction of motors. We shall find that many of the rules suggested in my former lecture are applicable also to the case of motors, and supply answers to many of the questions that naturally arise.

In the first place, shall we build motors large, or shall we build numbers of small ones? In my first lecture I proved that, in the dynamo used as a generator, the capacity for doing work increased as the fifth power of the linear dimensions; that by doubling a dynamo in length, breadth, and thickness, we had a machine weighing eight times as much, costing less than eight times as much, but capable of doing thirty-two times the work, and that with a great gain in economy in working. The same thing is true of motors. Suppose instead of building eight small motors, we build one large one, of doubled dimensions. It will not cost so much as the eight, will get though four times as much work as the eight put together, and will be more economical in working. I assume here, of course, that the large machine can be placed under equally advantageous conditions of supply.

This is by no means the only one of the points in the theory of the dynamo which can be applied to practice in the cases in which the dynamo is used as a motor. I will give another example.

In the prospect of an immediate field of usefulness opening out for motors, so soon as we have such a thing as regular town supplies of electric currents laid on, it is most important that motors should be designed, not simply to work with the constant electromotive force supplied at the electric mains, but designed also to work at uniform speeds. It is highly important, for example, in driving a lathe, and indeed many kinds of machinery, that the speed should be regular, and that the motor should not "run away" as soon as the stress of the cutting tool is removed. Now, in my second lecture, I spent some time explaining the methods by which M. Marcel Deprez and Professor Perry had solved a converse problem to this, namely, that of getting a dynamo to feed a circuit with currents, at a constant electromotive force, when driven with a uniform speed. The solution to that problem we saw consisted in using certain combinations for the field magnets, which gave an initial magnetic field, independently of the actual current furnished by the dynamo itself. Now, it is not hard to see that this problem may be applied conversely, and that motors may be built with a combination of arrangements for their field-magnets, such that when supplied with currents at a certain constant electromotive force, their speed shall be constant, whatever the work or no work which they may be doing. The one difficulty in the problem—and this is a mere matter for experiment and calculation—is to find the critical number of volts of electromotive force at which this will hold good. It is, in fact, the converse to the operation of finding the critical velocity at which one of Deprez's or of Perry's combination dynamos must be driven, in order that it may give a constant electromotive force. M. Marcel Deprez has, himself, constructed motors upon this plan. Some three years ago I saw one of Deprez's motors, which ran at a perfectly uniform speed, quite irrespective of the work it was doing. Whether it was lifting a load of five kilogrammes from the ground, or was letting this load run down to the ground, or ran without any load at all, the speed was the same. At the Paris Exposition Electrique of 1881 a large number of Deprez's motors were shown, running at uniform speed and driving various machines, lathes, sewing machines, &c.

Amongst others who have aimed at producing a motor to work at uniform speed are Professors Ayrton and Perry. Professor Ayrton informs me that one of these motors, weighing only 350 pounds, will give an effective power equal to 8 horse-power, and that "without any mechanical governor; without anything, in fact, in the nature of a moving governor, it always goes at the same speed, whatever work it has to do." Certain little legal matters connected with the protection of this invention have debarred Professor Ayrton from informing me more fully of the new machine, which, if it fulfils the promise of its inventors, will be a great step forward in the mechanical application of electricity. But I can hazard a guess that the arrangement for obtaining uniform speed is dependent on the prior condition that the motor be supplied, either with a constant electromotive force, or with a constant current of a certain "critical" value; and that the solution of the problem is virtually one of the cases of combination, the counterpart of which, as applied to generators, I discussed last week.

(TO BE CONTINUED.)

* These figures, and those which follow, are given on the authority of the President of the Munich Exhibition, Professor von Beetz. It is but fair to add that M. Deprez is not satisfied of their accuracy.

STORAGE BATTERIES.

[The *New York Sunday Herald* for January 28 gives the report of an interview with Mr. Edison. We this week give that part of the report dealing with storage batteries, and hope to give that dealing with lighting in our next issue. We have left out some of the more strongly worded sentences, and also the names, inasmuch as these do not affect the argument.—ED. *E.*]

"The storage battery is, in my opinion, a catch-penny, a sensation, a mechanism for swindling by stocking companies. The storage battery is one of those peculiar things which appeal to the imagination, and no more perfect thing could be desired by stock swindlers than that very self-same thing. In 1879 I took up that question, and devised a system of placing storage batteries in houses connected to mains and charging them in the day time, to be discharged in the evening and night to run incandescent lamps. I had the thing patented in 1879 (I forget the

Digitized by Google

date of the patent), but there is nothing in it. I rung all the changes on it. My plates were prepared like Planté's. The method of preparing them for charging is more tedious, but it is better than that of Faure, after preparation. You know the first storage battery was sent from France by Faure to Sir William Thomson, who was at first astounded by it. He was asked to endorse it, consented, and took a retainer; but, on investigation, he became convinced that there was nothing in it, and returned the retainer to the French company. The fact is, the more he investigated the more he found out the fallacy of the whole business. On account of what Labouchere calls a swindle this secondary battery has been used by the arc companies in England. One company alone, on the strength of an accumulator and an incandescent lamp copied from mine by ———, floated subsidiary companies whose aggregate capital was over 30,000,000 dollars, and immense sums were paid by these companies to the parent company for rights. This was the great ——— electric light bubble, in which millions were lost, and caused the now celebrated article of Labouchere. One of the leading spirits in the bubble is in this country at the present time attempting to do the same; but Carlyle's saying about 30,000,000 fools probably did not apply to foreign countries. "Scientifically, storage is all right, but, commercially, as absolute a failure as one can imagine. You can store it and hold it, but it is gradually lost, and will all go in time. Its efficiency, after a certain number of charges have been sustained, begins to diminish, and its capacity and efficiency both diminish after a certain time in use, necessitating an increased number of batteries to maintain a constant output. Owing to corrosion of the sustaining plates of the battery, the effect of local action, and other causes, too many to enumerate, the yearly depreciation of the battery is not less than 30 per cent. of its first cost if used daily. The facts are that there are two or three companies that have been organising subsidiary arc light companies throughout the country for some time past. In this arrangement the parent company made money by selling machinery, &c., to the working companies, but the latter are not making money, and have nearly ceased giving new orders. Now these parent companies, finding the call for machinery slacking, have come in with their secondary batteries. They now make this statement, which is the cleverest thing I ever heard of. Here, gentlemen, you have a large investment in machinery, &c., for furnishing light, but are not making any money out of it. Now, we have something by which you can utilise your machinery. You can work day and night, and can do more work. You can utilise your present plant in the daytime, and the electricity thus made in the daytime for incandescent lighting, and in the night have your plant for arc lighting direct. That sounds good and fair, does it not? The board of directors discuss the offer, and think it a good thing. Then they conclude to go into it. You know," said Mr. Edison, with something of contempt in his tone, "what the wisdom of the average board of directors amounts to. I will tell you where the fallacy in this arrangement lies. It consists in the fact that the cost of batteries to store this extra electricity that could be produced in the daytime would be twice as much as that of the station that produced it; so that, if the company has already 100,000dols. invested, and agree to utilise their machinery in the daytime by the addition of storage batteries, they will find that to carry out their desire it will cost them 200,000dols. for the batteries. I will guarantee that not one board of directors in a hundred will see it, and the parent company will not tell them of it until after they have purchased. It seems to be natural with boards of directors that if there be a wrong way to do a thing they will surely do it that way. Well, they have purchased the storage batteries, of course, at a cost of 200,000dols. On that investment, at the end of the first year, they have a depreciation of 30 per cent. To save themselves they will have to earn interest on their investment. They must earn enough to meet the extra depreciation on their plant running through the day, and will have to spend double the amount in coal to obtain the same output from the batteries, for the reason that they interpose between the source of energy and the light, a thing in which there is a loss both in charging and discharging, and a loss in standing, and that loss increases as the battery gets older, after a certain maximum is reached."

"What is the maximum of a storage battery?"

"It is about 50 per cent. You get the maximum of current when you utilise the full capacity of the battery, the same as in a steam engine, where, if steam is admitted for the full stroke, 50 per cent. of the steam or power is wasted, but you obtain the maximum power from the engine; but this is also the minimum of economy. Hence, to get the proper economy, engine builders only take one-third to one-fourth of the maximum power from their engines, but this adds to the investment, which is compensensated for by the saving in economy, which more than pays interest on increased investment. When they say that 90 per cent. is obtained from the battery they tell you what is scientifically true. They say they get 10 lights of 16 candles each per horse-power of current from a battery. Now that is true, and it is not true. If you get a horse-power of current from a battery it will give you 10 lights of 16 candles; but to get that you have to net all losses through the battery, through the wires, through the dynamo, and all that. They start off with a horse-power indicated in the engine. A certain amount of this is taken to move the engine and dynamo, and a certain amount is lost in the dynamo to convert power into electricity, because no machine is perfect; a certain amount must be lost on the wire connecting the station with the secondary battery; another amount is lost in charging the battery, due to its resistance and imperfection as a mechanism; another amount is lost during the interim between charging and use; another portion will be lost in discharging the battery through the lamps, and still another amount will be lost in the wire connecting the battery to the lamp. So that your horse-power will dwindle down until it will give you only about three lamps; whereas, if you worked direct you would probably get six lamps."

"You are hard on the battery folks."

"The reason I am down on these people is because I have a legitimate thing, and there is a loss of public confidence in it through their operations. We have never yet asked the public for money. Now, I don't want the people swindled, for I want our company to make money out of electric lighting in a legitimate way, by giving value for what is received, and, if it sells rights, to first prove to the purchasers their value by results, obtained in actual practice upon a large commercial scale, as is now being done, and the exposure of such things would make it much easier and better for me to advance my system on its true merits. The same swindle which it is designed to perpetrate upon the people of this country has already been carried out in England, and as a result people there have lost all confidence in electric lighting. The same people are here. We have entered suits against them in England, France, and other countries, and will sue them here. But these people know well that it will take some time to get a suit decided, and by that time they will have 'permitted the public to invest heavily.'"

"Then you consider storage batteries wholly impracticable. Is there no hope for their doing good, legitimate work?"

"None whatever. Except in a very limited number of cases, storage of gas could be made analogous to storage of electricity. One of the principal outlays of a gas company is for pipes. The average diameter of their mains is five or six inches. But, under pressure greater than they now force the gas through their mains, an inch pipe would answer under the storage principle of having a small gasometer in every house. The difference saved to the company by this arrangement would be about 15dols. for pipes from house to house, 20 to 30 feet apart. But the gasometer would cost a great deal more in each house than the 25ft. of pipe buried in the street. Besides, gasometers might not be just the thing in the hands of the public; there might be explosions; some of them might not have the room. The gasometer would require some little mechanism to reduce the pressure down to a limit where it could be burnt. Now, these little mechanisms are uncertain. The general intelligence of the public, when applied to mechanism, is also uncertain; and this has probably prevented gas engineers from introducing a system of local storage. The Electric Arc Company, which is seeking to introduce a system of storage, follow out the above idea exactly. Instead of using large conductors and low pressure electricity, as I do, they propose to save on the investment by using small conductors and high pressure electricity; and, to make this kind of electricity available, they reduce its pressure by means of a storage battery in the same way as high pressure gas in a small main could be stored in a gasometer and its pressure reduced to make it available. In the first place, the high pressure current is very dangerous to life. The depreciation on storage batteries alone, in a system of general distribution, would pay the interest on the extra copper sufficient to dispense with their use; and, second, if these small wires, carrying high pressure currents, were to be placed underground, as all systems must be to be financially permanent in large cities, the extra cost of the insulation necessary to prevent the leakage of the currents of so powerful a pressure would more than pay for the extra copper used in a system which carry low pressure currents and do not require so expensive nor so great an amount of insulation. The cost of our mains is about 15dols. from house to house. These mains are two feet underground, where the intellectual portion of the public cannot reach it to improve it, while with storage batteries, from 75dols. to 200dols. worth of batteries would be placed in each house to save about 9dols. in copper and interpose an uncertain device in which 50 per cent. of the article to be sold is lost." Mr. Edison here paused a moment, held down his head, and, quickly raising it again, said, in his quaint way, "Just as

Digitized by Google

soon as a man gets working on the secondary battery it brings out his latent capacity for lying."

"But suppose power was cheap, such as a water power, would it not pay to store electricity even at a great sacrifice of energy?"

"In utilising water power, even where the cost of water is, say nearly nothing, there is still the cost of plant for storing to be considered, and interest and depreciation added. Where is the use of this outlay when, in nearly every case, by connecting the dynamo direct with the turbine you can get the same result far more cheaply? But you will remember that water power is not so cheap after all. It is only occasionally you can run across a water power that has a surplus in every month in the year beyond the wants of those who utilise it. These storage men will tell you that lamps burn better fed from batteries than from the source of power direct. This is not so. They are very brilliant when they start, but more battery must be put on from time to time, or they will soon go down. If you have a battery that will run ten lights, and wish to run them until 10 o'clock p.m., you must have other batteries to reinforce it, or the lamps will diminish in candle-power before the expiration of the time it is rated for. Then, after turning off the lights, the batteries will lose about one-fifth of the charge remaining in them before being recharged. There is a natural law working against the storage battery, and that is that finely divided lead decomposes water. It is stated that when Sir William Thomson had his attention called to this fact he threw up the sponge. All metals are fuel. When oxidised they are ashes, and it takes energy to put them back again into a metallic form, when it is again fuel. Mr. Brush may say he has a secret compound. It is nothing more than a salt of lead. They use lead, and their battery is nothing more than a Faure battery, plain and simple. They say they cannot furnish these batteries for six months. There are shops in this city that could turn out 6,000 of their cells within three weeks."

THE TELEPHONE CASE.

JUDGMENT.

Last week we gave the judgment of the Master of the Rolls in the case of the United Telephone Company *v.* Harrison, Cox-Walker, and Company, which was an appeal on the part of the defendants against the decision of Mr. Justice Fry given in May last. This week we give the judgment of Lord Justice Lindley. We had hoped to have given that of Lord Justice Bowen as well, but the pressure on our space compels us to hold it over until next week.

Lord Justice Lindley, in giving judgment, said: In this case, which has taken a long time, and is of very considerable importance, I think it will be most convenient, so far as my own observations are concerned, to begin with Bell's invention, to see what it was. Having done that, to deal with the objections raised to this patent. And Bell's invention, as I understand, so far as it relates to telephony, which is all we are concerned in, is of this kind. He discovered certain methods of receiving and transmitting and reconverting the sounds produced in the human voice, and he described his method of doing this in what has been called the fourth and fifth plans of his specification. In the fourth plan he described an electro-magnet of metal plate, fixed in the manner pointed out in that plan to a figure connected with it. In this plan there was a battery current along the wire, which was essential; it was also essential there should be continuous undulatory currents. In the fifth plan, there are two modifications—one was of a permanent magnet with an electro-magnet in four pieces, and a piece of metal placed before it. In the second variety there is an electro-magnet with a separate battery, and there was a separate screw to this. What was done, as I understand the *modus operandi* of this instrument, was this—first of all, it had in transmitting the human voice created certain vibrations in that metal plate. These vibrations excited the magnet in front of which the plate was fixed. The excitation of that magnet produced a current in the coil which passed along the wire, and had a receiving end, and *vice versâ*—that is to say, the current was received by an induction coil—the magnet affected the plate, and the plate affected the magnet. His real discovery—I am not now criticising the description of it, or the language of any particular portion of it—his real discovery was this:—First of all, he discovered the importance of continuous undulatory electrical currents as distinguished from pulsatory. There was one very important part of this discovery, and that was the importance of one particular set of currents. The next thing he discovered was the best way of producing, transmitting, receiving, and reconverting these continuous undulatory currents so as to render the human voice audible. That was by using a metal plate, as described in the plans. Then there was a third one, which is important. He discovered the fact that the same instrument would act as a transmitter and receiver. You have in that the essence of this discovery. It appears to me that that discovery is described with sufficient clearness in the specification, and that the claims, when you look at them fairly, amount to a claim for the discovery in a wide sense. Taking it as our starting point, let us see whether it can be said with anything like accuracy that that was an old invention which had been anticipated. Let us look back at Reis's patent. I have read the whole of the evidence more than once, and as I understand it people have now discovered how there could be got out of Reis's instrument something which, if known then, might have had the appearance of anticipation. It appears from some portions of the evidence that Reis understood his instrument. There are indications of his knowing more about it than anybody else did. But the main feature of Reis's apparatus, as known in this country in 1876, was that it was a receiver which acted as a transmitter. I am quite aware that by speaking low and taking care you can get out of it effects which were never dreamt of before; but looking at the description, whether you take the German or the English text, it looks plain, that, as understood in 1876, this invention of Bell's was in immense advance upon it. It appears to me that, inasmuch as the instrument described and patented by Bell is mechanical and otherwise different from Reis's, I cannot possibly say that Reis's was in anticipation of Bell's, although I quite admit now that we can, by improved methods or more delicate manipulation, get out of Reis's effects never dreamt of. With respect to the Glasgow receiver, the case stands in this way:—The first thing was to understand that receiver and see what it was. It was, in fact, an electric magnet, angular in shape, had an adjusting screw, which was surrounded by a metal case something like a drum, and had a lid upon it which was secured, and I think, according to the evidence, it must be taken that it was tilted up. Upon the whole, the evidence is clear and strong that it was tilted up. It was made in Philadelphia, given to Sir William Thomson wrapped in a brown paper parcel, and when it was open it was tilted up, and in that shape Sir William Thomson began to try to use it. We know, in point of fact, it failed—why, I do not know: perhaps he had not sufficient time to attend to it. The attempts made by Sir William Thomson with this instrument before the meeting of the British Association had not been successful. At the meeting of the British Association this thing was produced, was placed upon a table, and was spoken of, examined, and seen by those who cared to see it. It was not then linked to or joined to any transmitter at all. The transmitter and receiver were not connected, and all that was said in substance was that in America Sir William Thomson said he had heard proceed from a thing like that the human voice. If we look at this Glasgow thing, and at the thing described by Bell in this specification and patented, it is impossible to say that they are in all respects and precisely the same—of course, identity is out of the question. There are differences which may be important or unimportant; but what I mean is that there are differences which are plain enough. For instance, they are not so much alike as two daisies—they are different things, differently constructed, and whether they are the same in effect is quite another matter; but I can affirm truly that the thing described and patented by Bell is not in all respects similar to the Glasgow thing. I attach immense importance to that, because if the thing described by Bell, and patented by him, were precisely similar to the Glasgow thing it would place matters in a very different position. But there were differences capable of observation and description. What do people know what information was given, what disclosure was made by the production of this Glasgow thing? There was, it appears to me, abundant evidence to show that any competent person could have made one like that, having seen it; but when he got it, what was it then? It was, as it appears to me, a useless thing, and nobody knew how to use it; and not being the same thing, but being different from the Glasgow thing, it seems extremely difficult to see how the Glasgow thing can be regarded as an anticipation of the patent. It is curious and instructive to observe what can be got out of this Glasgow thing now. Now, it is said you can get out of this Glasgow thing all you can get out of the patent and transmitter—that is to say, so far as I know, we have not had proof that that Glasgow thing can act as a transmitter. I do not say it cannot, and I should have thought there would not have been much difficulty in proving that. Although that Glasgow thing has been made to speak more or less well in this court, all attempts to make it speak, even in the courts below, failed, until it fell into the hands of one of the most skilful men in England, but before having the knowledge of 1881 and 1882 to guide us it was practically useless. Can any one, using the knowledge which we now possess, and the knowledge we had in 1876—can it be said in any fair, rational sense that that Glasgow thing anticipated Bell's? I confess I cannot bring my mind to that at all. I do not think it is a sufficient answer to say that now we can get out of the Glasgow thing the effects we can get out of the Bell patent. There are various methods of investigating the problem. Did it enter the head of any man in England at that time that the Glasgow thing would transmit and receive? It may be that that was so, but was that shown to the public? Was it ascertainable by the public in 1876? I think the answer to that must be "No;" and the two things not being the same, but being different, it appears to me to say that the Glasgow thing of 1876 was an anticipation of Bell's patent is not borne out by the evidence. No other anticipation is suggested. Reis's was eventually suggested, and the Glasgow thing was strongly insisted upon as an anticipation, but it appears to me that that must fail. The other point to which I shall allude may be dealt with shortly, and that is the question of infringement. I do not say that Mr. Hunnings's criticisms upon the specification drive us to the conclusion that there is evidence. On the specification the infringement is plain enough, and it was only by way of driving us into a corner Mr. Hunnings suggested that. There was this point made as to the construction of the specification, and as to the claim of these undulatory currents. I find that the specification was originally drawn, and that fourth claim was capable of being construed as claiming the production of those currents, and it might be fairly construed so. It would have been an independent thing for Bell to rest there without disclaiming. I am satisfied that that was claimed in the original specification, and the disclaimer is not to my mind so clear as it might be. The disclaimer in one place is subject to the claims which have been mentioned. It is difficult to say what is disclaimed and what is not. I confess that, looking at the specification, and understanding the invention as I think I do, it appears to me if we acceded to Mr. Hunnings's argument that the specification is altered by the disclaimer, we should be doing that which was never intended, and construe a document, capable of two constructions, in such a way as to render it invalid rather than otherwise. It is our duty to ascertain the true construction of the document; but, of course, in ascertaining what is the true construction, I take it we ought to apply our judgment to specifications in the same way as to other documents. It strikes me that Mr. Justice Fry is right when he says, if we put the construction upon this amended specification Mr. Hunnings asks us to do, we should be doing what is an absurdity. That appears to me to be a course which no Court should take. It appears to me that is the construction, and this specification is free from the objections urged against it. The conclusion I have come to is that the specification is good, and that the anticipation is not valid.

ORIENTAL TELEPHONE COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on Thursday, 8th inst., at the offices of the Company, Col. G. E. Gourand in the chair.

The SECRETARY (Mr. W. G. Hall) read the notice convening the meeting, and the minutes of the previous meeting were read and confirmed.

The CHAIRMAN said that the unavoidable absence of the chairman of the Company (John Pender, Esq., M.P.) accounted for his being in the chair. He remarked that the business was of a purely formal character, assuming the meeting approved of the resolutions passed at the last meeting, but the Articles of the Company made it necessary that all proceedings of the Company in extraordinary general meeting should be subsequently confirmed by a meeting of the shareholders.

The resolutions passed at the extraordinary general meeting held on the 24th January were then duly confirmed. In reply to a question asked by a shareholder as to the progress of the Company since the last meeting,

The CHAIRMAN said that not much time had elapsed since then, but something of a very important character had nevertheless been accomplished. Mr. Pender, at the last meeting, stated that negotiations were proceeding for the formation of an important subsidiary company, viz., one for Calcutta, which, he explained, would be upon the same lines as those of the Bombay company, with which they were familiar. The negotiations in question had so far reached a conclusion, that all the principal points are settled; indeed, this much has been done within the last twenty-four hours. A telegram had been received, giving the names of the proposed directors, and all those of a most satisfactory character. The terms might be generally expressed as advantageous to the Oriental Company as in the case of Bombay; in fact, more so, as a larger payment was to be made in cash, as well as in shares; but by this remark he did not wish it to be understood as implying that the terms were any less favourable to the Calcutta Company. As on the occasion of the last meeting, when Mr. Pender was able to report a satisfactory progress of the exchanges in Alexandria and Cairo, he was able at this time to say that this progress had continued, and even exceeded the anticipations of himself and his colleagues. An important circumstance might be mentioned in evidence of the favour with which the enterprise was regarded in Egypt, as well as the approval of the Egyptian Government, of the manner in which the Company had managed its business in these two places [hear, hear]. The Khedive had recently extended the grant to the Company, which originally was limited to Cairo and Alexandria, so as now to include practically all the important towns in Egypt. As originally explained by Mr. Pender, the Company was to develop the business in all the places of importance throughout the wide field of the Company's operations. After having demonstrated its utility, local companies were to be formed with local capital and support. He (Colonel Gourand) said there had been enquiries from Egypt with a view of purchasing the shares of the Oriental Company, which seem to indicate that telephone shares would be regarded with favour in that country. The Board had therefore determined to form a separate company for Egypt, and in order to accomplish this had recently registered in England a company under the style of the Telephone Company of Egypt (Limited). The Board had been fortunate in obtaining as chairman Lieut.-Gen. Fraser, late Secretary of the Public Works Department of the Government of India, a gentleman of very great experience and ability. The other directors so far appointed were himself (Colonel Gourand), deputy chairman, and Mr. James Pender.

The CHAIRMAN, replying to a further question, said that it was the intention of the Board to declare an interim dividend, pending the arrival of the accounts from abroad, which must of necessity be somewhat delayed, owing to the wide distribution of the Company's interest; but notwithstanding this, through the efforts of the manager and secretary, Mr. Hall, whose services were of the greatest value to both the Company and directors, this delay would not amount to much. The Chairman added that the amount to be now paid as interim dividend on the ordinary shares would be 2½ per cent., but he hoped that something more substantial would be paid in the course of the next few months, when the annual report and accounts to the 31st December last would be submitted to the shareholders. The amount of this further payment would necessarily rest with the shareholders themselves.

A vote of thanks to the chairman brought the proceedings to a close.

[The above report appeared in our Special Edition of Saturday last.]

THE DIRECT UNITED STATES CABLE COMPANY.

The half-yearly ordinary general meeting of the shareholders of this Company was held at the City Terminus Hotel, on Friday, the 9th inst. John Pender, Esq., M.P., presided.

The SECRETARY having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen—The revenue for the half year to 31st December last, after deducting out-payments, amounted to £77,469 8s. 3d., and the working and other expenses, including debenture interest and income-tax, absorb £22,786 3s. 2d., leaving a balance of £54,683 5s. 1d. as the net profit of the half year, making, with £282 16s. 8d. brought from the previous half year, and £324 12s. 1d. reserved last half year for law charges, a total of £55,290 13s. 10d., which has been appropriated as follows:—Interim dividend of 5s. per share to 30th September last, £15,177 10s.; interim dividend of 5s. per share to 31st December last. £15,177 10s.; written off preliminary expenditure, £2,213 4s. 1d.; set aside to reserve fund, £21,435 13s. 9d.; carried forward to next half year, £1,286 16s.—total, £55,290 13s. 10d. The revenue, at the 2s. tariff, exhibits an increase of £12,955 over that for the corresponding period of 1881; but a comparison of the receipts is again unreliable, owing, firstly, to the 1s. tariff having been in operation during the five months ending December, 1881, and, secondly, to the arrangements concluded in May last with the American companies. The revenue at the present tariff of 2s., however, may, no doubt, be considered satisfactory. Turning to the expenditure, it will be seen by Abstract A, page 8 of the accounts, that the expenses in London remain practically the same as in 1881, but the expenses at stations, as shown by Abstract B, page 9, exhibit a substantial reduction, amounting to about £3,400, due principally to the arrangements entered into with the Western Union Telegraph Company in May last. The only item showing any appreciable increase is that of repairs and renewals to buildings, the additional outlay in this case having been incurred in placing the Company's station buildings at Ballinskelligs in a sound state of repair. On the whole the working and other expenditure shows a reduction of £2,788, as compared with the corresponding period of 1881. The present market value of the Company's investments, standing in the balance sheet at cost of £296,053 12s. 5d., is about £307,000, or, say, £11,000 (equal to 4 per cent.) more than their cost to the Company. The annual interest from these investments will now amount to about £11,000. Now, gentlemen, these figures I think must be very satisfactory to you, and as the past half year has been one rather remarkable in its incidents I thought it necessary to go, perhaps, a little more into detail to-day than usual, so that you may not only understand exactly the position which your Company occupies at the present moment, but also that you may have a fair idea of Atlantic telegraphy as well. When I had the pleasure of addressing you six months ago there were many rumours of further competition from new cables. We had just concluded our agreement with the American Cable Company, and a working arrangement with the Western Union Company of America. We had given the 1s. tariff a fair trial, and the result was so unsatisfactory that the various companies interested were obliged to revert to the 2s. tariff. We are now more convinced than ever that the 1s. tariff does not sufficiently influence the telegraphing public to make them increase the number of their messages to such an extent as would give us the same amount of money at 1s. as we can earn at 2s.—in short, the 1s. tariff would not yield enough to enable us to pay much more than our bare working expenses. We then found ourselves in the face of a new threatened competition, which had been talked of in America, connected with two powerful elements, the one being headed by the chairman of the Baltimore and Ohio Railway, and the other by Mr. Bennett, of the *New York Herald*—two men occupying important positions. They complained that, owing to the first cable arrangements which had been made, they were placed entirely in the power of the Western Union Company, and that it would be impossible for them to carry on an independent land line system with success unless they had the privilege of sending their messages on the same terms as those enjoyed by the Western Union Company or had cables of their own. I found it very difficult to meet this argument, and, with a view to better understand the whole position, and also with a view to have our arrangement modified, if possible, so as to have an independent system of Atlantic telegraphy, I proceeded to New York, determined to inquire into the whole question. On my arrival there I found that by this time the Western Union Company had entered into an agreement with the American Cable Company, so that the Western Union Company was literally working and controlling on the American side the whole of the trans-Atlantic cable traffic. And I found merchants, newspaper proprietors, and others all denouncing in no measured terms what they called this vast monopoly which had been established, and which they regarded as detrimental to their interests. I represented this state of affairs to some of the leading members of the Western Union Company; but, before going fully into the question, I resolved to travel over a great part of the Western Union system, so as to enable me to judge of how far that system was entitled to the position which it had assumed on the American continent. I may mention that, during my stay in the United States, I travelled something like 9,000 miles. At every point that I stopped at while I was there, even where the population was very sparse indeed, I found the Western Union represented. And here let me take advantage of this, the first public opportunity I have had since my return home, to express my cordial thanks to the heads of the various railway systems in that country for the extraordinary facilities they afforded me over their various railroads, and for the great attention and courtesy which I invariably met with at their hands. I may say, gentlemen, accompanied by one or two American friends, that we had every luxury that could be possibly placed before us, and we travelled over that 9,000 miles without its costing one shilling to this Company—entirely at the cost of the American railway systems. I think that is most creditable; at all events, we can do nothing of the kind in this country, and, therefore, I am sure that you will agree with me that at a meeting like this, where we are addressing our shareholders, we should one and all recognise the generous treatment which your chairman received. I also especially desire to take the same opportunity to convey my heartiest and best thanks to the Western Union Company. At New York the president, Dr. Norvin Green, and the general manager, General Eckert; at Chicago the general superintendent of their western division, Colonel Clowry; and, in fact, all I met connected with the company, were everywhere unceasing and successful in their efforts to make my visit to their country both interesting and instructive. I visited some of the most important cities and a vast deal of territory as yet unoccupied, but in the course of being developed, more particularly that portion which the Northern Pacific line traverses. Along the whole route the territory is very much as nature made it; but at the stations along the railway towns are springing up, which in a few years are likely to become important centres. Population seems to accumulate there by leaps and bounds, but even where this growth of population had only began I found that the Western Union had established offices; in short, I was struck with their omnipresence. That their system not only covers an enormous area, but that it is well and efficiently worked was to my mind an undoubted fact, and if the American people could be satisfied with one telegraph system, I believe that it could not possibly be done better than by the Western Union Company. They have in the West at Chicago, St. Pauls, Denver, Omaha, St. Louis, Cincinnati, in fact at all the leading important towns, men of the highest intelligence, and evidently men who have not only developed the Western Union Company, but have also made an important position for it and for themselves. This fact alone gave me great confidence in the working of the Western Union system, and I felt that the arrangements we had made with them were fully justified as enabling us, through our trans-Atlantic cables, to reach all points throughout the United States and Canada with the least possible delay. On the other hand, I found that there were many who thought the monopoly injurious, and who were more or less instrumental in getting up small competing lines. I was not astonished at this, but felt that it would have shown wisdom on the part of the Western Union Company if they had not endeavoured, as they had done so frequently, to buy up these small competing concerns, which were brought out evidently for the purpose of being sold at a profit. It would, in my opinion, have been better for the Western

Digitized by Google

Union Company if they had shown, by their vast organisation, that they were able to carry traffic more promptly and efficiently than any competing company. In short, the contrast would have been so apparent, and so much in favour of the Western Union Company, that I believe that such competition would rather have benefited them than otherwise. These eight competitious rather benefit than injure the Western Union. This I have strongly represented to the Western Union Company. I have always held that opinion. I hold it now, and I think we have carried it out, so far as the public is concerned, in the system of submarine telegraphs over which I have the honour to preside. Gentlemen, having satisfied myself on the efficiency of the Western Union system, and endeavoured, as far as I possibly could, to avert competition, I called upon Mr. Garrett. I may say that that gentleman is chairman of the Baltimore and Ohio Railway. He is a man at the very head of railway companies in America, a man of high honour and integrity, a man that is very much esteemed and valued by the people of Baltimore. I had the honour of making his acquaintance in England, and I received from him a thorough hearty welcome. When I visited him I went into the question of the competition which he was about to establish with Mr. Bennett. I explained to him the policy which I thought might, if carried out, suit his purpose quite as well as putting down cables of their own—in short, better. The result of that conversation was that he said he would be satisfied if that policy was carried out, and that at all events he would be disposed to give it a fair trial. I afterwards had a similar conversation with Mr. Bennett, and the result was pretty much the same, so far as what I may call the Garrett-Bennett opposition. I believe for the time that that is at an end. However, I do not say that upon any distinct authority from those gentlemen, but they have now made arrangements for giving the system, as they said then that they would, a fair trial. I considered that he had reason on his side, and I am glad to inform you that we have now succeeded in establishing the policy of an independent office in New York, which the Direct Company and the French Company work entirely independently of the Western Union Company. And here let me say that, since we entered into arrangements with the French Company, we have received their most cordial co-operation. We have found them, as we expected, loyal in every way. I went over to Paris, and reported the result of my mission to America, and received a most hearty recognition of what had been done, and an expression of their thorough appreciation of the advantages which were likely to result therefrom. I think that the establishment of the independent office in New York ought to satisfy not only the American telegraphing public, but also those who have been instrumental in bringing out competing land lines to the Western Union. I have thought it desirable to refer to my visit to America, and to say something about the Western Union system, because it is a system which is probably, in its efficiency, only to be compared with our own system in England, which is worked by Government, with this difference, that being worked by private enterprise, and being stimulated more or less by competition, I think the Western Union have shown greater results during the last ten years than our system has under Government management. I think that the science of electricity has received more encouragement, and has been more developed. The reduction of rates has during that time also been greater in America than in England, and altogether I think it would be well if our Government took a leaf out of the book of the Western Union Company. Having said this much about the land telegraph system of America, I must now say that I believe that to have a thoroughly efficient system of telegraphy, not only between New York and Europe, but also between New York and the vast territories of America, telegraphs must be worked under such arrangements as will give the lightning its full value and force. It would never answer if any one company had power to stop any message. The systems must be so organised as to be what I may call an universal system of telegraphy. This has always been our policy, and I shall always continue to develop it. I have had experience in our Eastern cable system, in which, owing to working arrangements, there is uniformity, and which connects all the centres of trade throughout the world, and there is no point in that system at which there is any stop or friction. To illustrate speed and uniformity between international telegraph systems, I may refer to an instance which occurred on the morning of Sir Garnet Wolseley's decisive victory in Egypt. At about ten o'clock (local American time) on that eventful morning the train in which I was travelling stopped at a little station on Indian territory, in Nebraska, and I received a despatch informing me of the English victory, and I was able to telegraph there and then to Sir Garnet that from a land where civilisation is only dawning I sent him congratulations to the land of the Pyramids, and I may say that these telegrams were exchanged in less time than is represented by the difference of hours between the two points. I may now say that probably our Atlantic system was never in a more satisfactory position than at present. There are eight cables. We are all working amicably and at a moderate tariff. We have established an independent office in New York to meet the requirements of those who felt there ought to be two distinct systems instead of only one, and I cannot see, therefore, at the present moment, any excuse for the laying of additional cables, because all the reasonable requirements of the general public have been met by the policy which we have now carried out. With regard to the threatened competition, which I will call the Garrett-Bennett scheme, although I am not authorised to say that they have entirely abandoned the idea, still they are satisfied with the arrangement we have made, and are giving it a trial. I may, therefore congratulate you and the Atlantic companies generally on the fact that we have before us—for some considerable period at least—freedom from that dread of more cables which has so materially damaged the value of our property in the market. There has also been an idea that if any one were to lay an Atlantic cable or cables the existing companies would be sure to step in and purchase them at a profit. I think I may say without hesitation that that time has gone past. It is true that an extraordinary transaction took place between the American Cable Company and the Western Union Company, which gave an enormous profit to the Cable Company; but I do not think for one moment that such an arrangement is ever likely to take place again, and it would, therefore, be well for those who have an idea of promoting companies for the purpose of getting a large profit out of them to remember that the present cables are equal to more than double the amount of traffic now carried, and that there is not another Company either in England or America which would be likely to enable them to realise any profit upon cables which had been promoted simply for the purpose of gain by sale, and not by legitimate working. Although I have not referred to the Anglo Company, which is, after all, the senior company, having four cables and receiving the largest share of the receipts, I may mention that their managing director has throughout been consulted in all these matters, and that he is thoroughly in accord with us in the policy which we have so successfully carried out. But the suggestion of the policy and the expense of carrying it out rests with the Direct Company. It may be well to say a few words as to the present value of Atlantic cables, as you constantly hear the cry of the capitals being watered, &c. No doubt the capitals of the different companies have been largely watered, but it matters very little what the portion of water is. The real question is, what is the value of the cables to-day? Take, for instance, the Anglo-American Company. They have four cables, three of which are comparatively young; the fourth (or what may be called the Brest cable) is the oldest cable at the present moment operating in the Atlantic. Last summer the Anglo Company spent £90,000 in repairing it. This not only gave them a living cable, but established the fact that a cable twelve years old could be picked up in 2,000 fathoms, proving that the strength of the cable still exists, and we know now, from experience, that the gutta percha—the heart of the cable—does not decay. Therefore, we may assume that this twelve year old cable may be as good for the next twelve years, and, probably, a much longer period, as it is now. Those four cables of the Anglo Company would cost to replace at the present moment from 3½ to 4 millions sterling. They carry with them the goodwill, which is worth a very considerable sum, having a monopoly of shortest route. They were the pioneers of this deep sea system of telegraphy, and are entitled to some monetary compensation on that account, but what is the market value of those cables to-day? Just about the price that I have named. Therefore the watering is perfectly understood, and is taken into account by the general public. Now take the French Company. The capital of that company is £1,680,000, they have one cable only, which, through financing and other circumstances, has cost them a very large sum of money; but what is the market value to-day?—why, about £800,000. The Direct Company's capital has been the least watered, but what there is was introduced into it before the present Board had anything to do with the Company. To replace our entire cable would cost about £900,000, the value in the market is about £800,000. It is now nearly six years since the management has been in our hands, during which period we have regularly paid a dividend of 5 per cent. per annum, and in the same period we have placed £290,000 to reserve. At the same rate of progress, in another six or seven years we shall have enough money in our hands to procure a new main cable, but as our knowledge of cables is daily becoming more complete, as was instanced the other day by the picking up and repair of the Anglo Company's Brest cable, I hope to find that, by the time our reserve fund is sufficient for a new cable, that our present cable is still working, and still likely to last for many more years, in which case we should be able to defer laying another cable, and consequently the interest from our investment of the reserve fund would provide us with a large revenue, in addition to the ordinary revenue earned by the existing cable. We should then, in fact, have two sources of revenue. But the most remarkable company is the American Cable Company. They made two cables, costing them less than £1,400,000. They leased these cables to the Western Union Company for fifty years for £2,800,000, to give 5 per cent. upon this increased value, or, say, 10 per cent. upon the original cost: but notwithstanding this high rate of interest, and the nature of the bargain, which restores to them at the end of fifty years their cables in as perfect working order as they are now (which means, I should think, new cables), I say, notwithstanding all this, the market value of these cables to-day is about £1,900,000. But, unfortunately, at the present moment, this transaction of the American Cable Company with the Western Union is so well known that there are promoters who now argue that if they can lay two cables they are very likely to make (as they say the American Company have made) a million sterling by the transaction. They make a great mistake. They look at the million as immediate profit, but ignore the fact that if those cables were sold at their market value to-day they would show a very small profit indeed. Besides, as I have before said, there is no likelihood of a second transaction of this kind taking place in America, and such a transaction would be quite impossible in England. I think these remarks are necessary quite as much for our own shareholders as for the general public, and good advice, if they choose to take it, to those promoters who are so anxious to benefit themselves by getting further competing cables for the Atlantic under the guise of being public benefactors, but whose first consideration is how they can make money by the operation. At present there is no better telegraph service in the world than the Atlantic service. I believe the public generally are now satisfied, and I hope that with quiet we shall so develop the traffic as to be able to increase our reserve if not our dividends, but, whether one or both, to increase the value of our property, and public confidence in it as an investment. I now beg to move:—"That the report of the directors, dated the 1st day of February, 1883, together with the statement of accounts for the half year ending 31st December, 1882, annexed thereto, be, and the same are hereby, adopted."

The resolution was formally seconded by Mr. W. FORD.

Mr. GRIFFITH: Your speech, Mr. Chairman, is so full of information and instruction that I cannot but suggest that it would be an advantage to us if we had an opportunity of considering it more at our leisure. You have given us a sketch of the whole system of telegraphy, and have shown us what able measures have been taken in America, and you have also entered upon other topics which are most important, and I would suggest that the speech to which we have listened should be printed, and a copy sent to each member. We shall then be able to appreciate more the great efforts which have been made in our services.

Mr. JOHN NEWTON: I suggest that the next time you give us a little more time. There is a most important Anglo meeting going on, and although we should like to stay here, we really must leave, because we want to attend. I think the one point you have mentioned of your visit to America is of such vast importance, that really on this side of the table I think some acknowledgement should be given on the part of the shareholders for the cordial welcome you received.

The CHAIRMAN: Previous to this we have held the meetings at twelve o'clock, and the Anglo-American meetings have been held at two o'clock. The Anglo-American made their meeting at twelve o'clock, and so we arranged for ours at 11:30, but as I know there are many anxious to go there, I am

Digitized by Google

only sorry that my remarks have kept you so long. He then formally put the resolution, which was carried unanimously. He next said, will any gentleman propose the election of an auditor?

Mr. JACKSON: I beg to propose that Mr. John Sawyer be and is hereby elected one of the auditors. I will not detain the meeting under the circumstances that have been gone into, but still I wish to say, while I propose this gentleman, he is a shareholders' nominee, and I have satisfied myself that he is a most efficient gentleman, and well acquainted with the accounts, and he has been concerned in auditing the accounts, and he is a brother of the late auditor. He is, besides, auditor for several public companies of very great importance, amongst which I mention the *Graphic* Newspaper Company (Limited), and, therefore, I think he is a man in every way entitled to our confidence. But I may call attention to the fact that hitherto we have had a rather meagre note appended to the accounts, and in the future I think it would be desirable to enter more into detail, stating that the auditor has compared with the books the vouchers, the certificates, and all these matters of detail. He should state that all those had been thoroughly examined. With regard to the other auditor, Mr. Griffiths, I may say that he has given me personal satisfaction, and he used at one time to state that he had gone through all the securities of the Company, and satisfied himself of their existence.

Mr. HINTON formally seconded the motion.

The CHAIRMAN: Mr. Griffiths would like to say a word on this subject.

Mr. GRIFFITHS: I beg to assure you that the duties of auditors have been very thoroughly fulfilled. We have examined everything that it was possible to examine. I am thoroughly satisfied, but I never like to put a long certificate on accounts of this sort. If I detailed some of the work I have done questions might be asked as to whether I have done more or not, and I have satisfied myself of the existence of all the securities referred to in the balance-sheet.

The motion was then put and carried unanimously.

The CHAIRMAN: I think, gentlemen, if there are no further remarks, that closes the business.

Mr. JOHN SAWYER: I beg to return thanks for the honour you have done me in electing me auditor. I appreciate that not only on account of the Company, but to be associated with Mr. Griffiths, whom I have known now for some considerable time, and I am able to say that your accounts are thoroughly looked after and very efficiently audited.

The CHAIRMAN: That concludes the business.

Mr. JACKSON: It would be most uncourteous to separate without a vote of thanks to the chairman and directors. I beg to propose that the best thanks of the meeting be given to the chairman and board for their services during the past half year.

A SHAREHOLDER formally seconded the motion, which was carried unanimously.

The CHAIRMAN: Gentlemen, on behalf of my colleagues and myself we only regret that our time has been so limited to-day, because there is nothing pleases the Board and myself so much as to have the criticisms of our shareholders. We come here before you once in six months. We think you are entitled to inquiry, and although we give you the best information we can on the business, still there are always some minds who can find some spots that may be worth considering and discussing.

The proceedings then terminated.

[The above report appeared in our Special Edition of Saturday last.]

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).

The ordinary half-yearly meeting of the above Company was held on the 9th inst., at the City Terminus Hotel, Cannon-street, the Hon. Robert Grimston presiding.

The SECRETARY (Mr. T. H. Wells) having read the notice convening the meeting, the report of the directors was taken as read.

The CHAIRMAN said: In the unavoidable absence of the chairman, Lord Monck, from illness, I have been requested to occupy the chair on this occasion. I must ask, therefore, gentlemen, for your kind indulgence, hoping that you will take the will for the deed. In one respect I appear before you under very happy auspices, and that is that all our cables are in good working order [applause]. When we met here six months ago, our Brest cable, or as it is generally called our 1869 cable, was broken in mid ocean; and a gentleman, who assumed the name of "An ex-Stockholder," went to the trouble and expense of circulating amongst the proprietors two letters, in which he prophesied that the 1869 cable never would be repaired, for that it was practically defunct and utterly useless. A man who prophecies about submarine cables is a very bold man indeed, and he would do well to remember the old distich—

"The easiest way to increase your store
Is to prophecy after and not before."

[Laughter]. Now within a very few weeks of the "ex-Stockholder's" prophecies, they were all falsified; the 1869 cable was repaired, and it has worked splendidly ever since. It carries on an average 4,000 words a day, and it could carry treble the amount if it were required [cheers]. The cost of repairing this cable has been very large indeed, very much larger than your directors had any reason to expect when they sent out the expedition to do it. In some respects we were somewhat unfortunate; upon two occasions when the work was very nearly completed, in fact I had been told that in another hour the work would have been done, the wind got up, and the cable had to be buoyed. Then the storm carried away the buoys, and this and the grappling of the cable had to be done over again. The result was that this expedition lasted between four and five months, and what with the value of the new cable that was expended it has come to the large sum of more than £90,000. We shall not have to go and borrow the money at a high rate of interest, for we have it in our renewal fund, and the whole cost of this expedition will be borne by that fund. Now, consider for a moment what would have been the position of this Company if we had no renewal fund. When our 1865 cable failed we should not have been able to replace it with a new cable as we have done; and, again, when our 1869 cable failed we should not have been able to replace it with a new one. And without the money in our till I do not think we could have ventured to send out a costly expedition to repair this 1869 cable, so that we should have been a Company with one cable, and that cable twelve years old. That would have been the position of the Anglo-American Telegraph Company if you had not had the prudence to sanction the additions which we have made from time to time to the renewal fund [applause]. Thanks to the renewal fund, we have now four cables in good working order. Now, in the seventh paragraph of this report allusion is made to our having raised the rate of tariff from one shilling to two shillings a word; and I wish to make a few remarks on that subject. We were induced by the desire of the public to make the experiment of the one shilling tariff, and I must confess I was one of those sanguine persons—if you will not apply a harsher term to it—who believed that a shilling tariff would amply repay all the companies, that there was business enough for all, and that this would become permanently the tariff of the future. We tried this experiment for ten months, and most grievously was I disappointed. The public, who were ready enough to cry out for a reduction of the tariff, were not quite so ready to bear their share of the expenses. In the result they did not support us in the manner we had a right to expect from so liberal a reduction. In the ten months during which we carried at the shilling tariff, as compared with the corresponding ten months at a higher rate, not this Company only, but the joint-purse, lost £290,000, or at the rate of very nearly £1,000 a day. Well, gentlemen, will anybody have been surprised that we entered into an arrangement with Mr. Jay Gould, a part of which arrangement was that the tariff should be put up to 2s. The public, I am sure, have no right to complain; they would not support us; it is their own doing, and they forced us into it. I have here a comparative statement of the tariff after we had raised it, and of the tariff before we had raised it, and that is very instructive. In August, 1882, our receipts were £70,430; in 1881, at the 1s. tariff, they were £51,690. In September they were £85,550, against £51,920; in October, £93,740, against £52,440; in November £89,390, against £49,860. There is a difference for the two latter months of £40,000 each. In December they were £78,150, against £50,280; and in the last month—January—they were £83,930, against £47,630; making altogether an increase for the six months of £206,670. Is it, then, to be wondered at that we entered into that arrangement with Mr. Jay Gould? Now, gentlemen, with respect to the accounts, I think there is very little to remark upon. The only thing I have to say with regard to the accounts is that, in salaries and wages, there is a saving of rather more than £550. In the general balance-sheet there is one item that requires explanation—sundry creditors, £125,731. The fact is that we have not yet paid to the Telegraph Construction and Maintenance Company an amount of £80,000 pending its adjustment, but we have the money all ready on deposit, and I expect that we shall make the payment some time in the course of next week. There is one other matter on which I wish to say a word before I sit down, and it is this. I regret to have to announce the resignation of my friend Mr. Rate, a gentleman in whom I have the greatest confidence, and upon whom I relied very much for advice at all times. I am sorry to say that he has now retired from the Board, and the directors have elected in his stead a gentleman well known to people who have anything to do with Atlantic telegraphy, I mean Mr. Cunard, and I hope he will worthily fill Mr. Rate's place. Gentlemen, I will now move "That the report of the directors and accompanying statement of accounts to the 31st December, 1882, submitted to this meeting be, and the same are, hereby received and adopted; and that the following dividends, all free of income-tax, be now declared—that is to say, a balance dividend of one per cent. upon the ordinary stock for the year ending 31st December, 1882, making with the previous payments two and three-fourths per cent. on that stock for the year 1882; secondly, a balance dividend of two per cent. upon the Preferred stock for the year ending 31st December, 1882, making, with previous payments, five-and-a-half per cent. on that stock for the year 1882" [applause].

Sir DANIEL GOOCH, Bart, M.P., briefly expressed his pleasure in seconding the motion.

Mr. BROWN asked whether there was not £36,000 over the corresponding period of last year, and how it was the poor Deferred shareholders got nothing?

The CHAIRMAN replied that there was not a sufficient balance of revenue account to pay any additional amount beyond what the directors proposed to pay.

Mr. JOHN NEWTON said he was sorry their meeting clashed with that of the Direct United States Cable Company, which was held about the same time, as he was anxious to get all the information he could as to these properties. If the shareholders of the Anglo-American Telegraph Company present at this meeting had heard the speech of the chairman of the Direct Company some half-an-hour before, they would have felt the greatest satisfaction as to the excellent working condition of the cables of the two great companies. The oldest cable they had been working, as he heard from the chairman of the Direct Company, was some ten years old.

Mr. HENRY WEAVER: Thirteen.

Mr. NEWTON: Well, thirteen. That had been picked up from the bottom of the sea, from a depth of 2,000 fathoms. This had put cable property on the footing of a good investing property. They might look to the future, perhaps, three times as long as they might have otherwise looked, and feel that their property would in perhaps 20 or 30 years be in the same condition by expending a small sum of money from year to year upon it. They would, therefore, hope to continue to derive satisfactory returns when they took into consideration the market value of their property.

A SHAREHOLDER remarked that he thought the Deferred shareholders had some claim to consideration [hear, hear], and that they ought to have some portion of the £36,000. If they were allowed one half per cent. it would be something of an encouragement to those who had been waiting a long time and who had received nothing. He, therefore, moved as an amendment that they should have one half per cent. paid out of the reserve fund.

Mr. POTTS said he thought the last speaker was under a misapprehension. If he were not mistaken the Articles of Association stated that the Preferred shareholders must receive 6 per cent. before the Deferred shareholders could receive a sixpence [applause].

The SHAREHOLDER said if his motion were not regular he would withdraw it.

Digitized by Google

Mr. POTTS said, inasmuch as the Preferred shareholders only recieved 5½ per cent., at present the Deferred shareholders had no case.

Mr. WEAVER: You are quite right.

Mr. GRIFFITHS expressed his regret at the absence of Lord Monck, who was a gentleman of undoubted talent, full information, and genial manner. He agreed with the chairman as to the advisability of the arrangement with Mr. Jay Gould, but he doubted whether it would not have been better to have entered into that arrangement before the war rather than subsequent to it. The chairman had told them that the war cost them £290,000, or £1,000 a day, and they might have saved that sum, and thereby have increased their dividends—at any rate, the dividends of the Deferred—and at the same time have made their Company much more secure. He thought their past policy had been a fear of bogies, and was glad there were signs of that policy being given up, and a more peaceable one being adopted. Mr. Pender, who had been in America, had told them that there was a very ill-feeling growing up there because the Western Union had monopolised the whole of the land traffic, and that, in consequence, numerous bodies objected to being under such control, and were likely to start new cables, in order that they might be independent of it. Mr. Pender said that the Western Union system was developed in a wonderful manner, but it was creating a feeling against its central tyranny. He also told them that he had made arrangements by which the Direct and the French Company might have a separate office in America. The consequence would be that there would not be this ill-feeling in the future on the other side of the Atlantic, and for some time to come they need not anticipate any rivalry from new cables. He thought they might look forward to a more settled state of affairs, and trusted the large reserve fund they had would not be used to place more cables under the water, for he understood that those which they possessed could carry more than double the messages that could possibly be sent. He hoped the reserve fund would be applied to equalising the dividends from time to time [hear, hear]. The Preferred shareholders would then get their interest, and the Deferred shareholders would look forward with confidence to some return.

Sir H. JOHNSTON said the accounts were of a very meagre character, and he thought they were entitled to have some further explanation of the £100,000 and upwards which was put under one head.

The CHAIRMAN said there was an item of £19,027, balance of account, owing to the Western Union Telegraph Company of America. They also owed £2,407 to the Postmaster-General, and £2,678 in traffic balances to the Eastern Telegraph Company. Any proprietor could obtain every information at the office. With regard to the cables, there was no intention to increase their number [hear, hear], but they had to keep them in working order [applause]. They could not tell the life of a cable. Two—the 1865 and 1869 cables—had failed within ten years. One of their present ones had lasted between thirteen and fourteen years, while they had two others, one of nine and the other of eight years.

The resolution was put to the meeting and carried unanimously.

On the motion of the CHAIRMAN, seconded by Sir Daniel Gooch, the Marquis of Tweeddale and Mr. Cyrus W. Field were re-elected directors of the Company.

The auditors, Mr. Joshua Dean and Mr. Francis Glass, were subsequently re-appointed for the current year, at a remuneration of £100 per annum each.

A vote of thanks to the chairman closed the proceedings.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY (LIMITED).

The nineteenth ordinary general meeting of this Company was held at the City Terminus Hotel, Cannon-street, on the 13th inst., under the presidency of Mr. George Henderson.

The SECRETARY (Mr. William J. Tyler) having read the notice convening the meeting,

The CHAIRMAN said: We are very glad to meet you with so good a report, and to put before you accounts showing such excellent results of the year's business, enabling us to distribute a handsome dividend, as well as to strengthen the Company's financial position by so material an increase to our reserve. As our business increases so also must the reserve, in order to supply the requisite working capital. How to place our new buildings and machinery within the limited space at our disposal has been a matter of considerable difficulty and anxiety to our manager, Mr. Gray, but this he has successfully overcome. As regards our factory at Persan-Beaumont, we have been obliged to acquire additional land to connect our place with the railway, and to give room for necessary extensions. Our chief cable expedition—that for laying the Central and South American cable — was carried out under the management of Mr. R. K. Gray, and both he and his staff deserve the thanks of the shareholders. The Company's cable ships are all in first-rate condition. The "Dacia" and "International" are now under charter, and the "Silvertown" is on her way home with a freight which will go towards her coal bill and other ordinary expenses. We hope that the proposal to do something for our workpeople will meet with your approval. Mr. Gray will give you some information as to how we intend to proceed in this matter, but I may just mention that, in the interest of employer and employed, we think that those of our people who come to their work from a distance should have a comfortable place in which to take their meals, and that, by means of lectures and classes, they should have opportunities of self-improvement and training to fit them for doing their work efficiently and intelligently, and that rational entertainment and recreation should be provided for their leisure hours. I may mention that it is only proposed that the first cost of erection should be borne by the Company, the cost of maintenance and everything else by the workers themselves. I do not know that I need detain you longer, but we shall be happy to hear any shareholder who may desire to address the meeting. He then moved the adoption of the report and accounts, and the payment of a dividend of £1 a share and a bonus of similar amount.

Mr. S. W. SILVER: I have very great pleasure in seconding that.

Mr. DIXEY stated that he was not a very large shareholder in the Company, but having been connected with it for many years he might express the intense pleasure and satisfaction he had felt in reading the report which had been submitted to the meeting. It was pleasant to find that every department in connection with the Company had been fully employed during the past year, that the item of debentures and securities in other companies had been greatly reduced, that certain securities had been disposed of at a considerable profit, and it was also pleasant to find that £100,000 had been added to the reserve fund, and that after paying 25 per cent. to the shareholders there yet remained a balance of £36,311 to be carried forward to next year—a sum almost double that which was carried forward in the previous year. He ventured to say that a report such as that had seldom been submitted to any body of shareholders, and they might well congratulate the directors and each other that day upon the prosperity which the Company had attained. There was, too, a paragraph in the report to which he had not yet alluded, but which had struck him as constituting its grandest feature, and that was the suggestion made by the directors to appropriate the sum of £6,000 towards the building of dining rooms and a hall for the comfort, instruction, and amusement of the workpeople at Silvertown. That was a proposal which appealed at once to their highest and best instincts, and one which he trusted would commend itself to the great body of the shareholders; for it could not be denied that the workpeople at Silvertown had contributed to the success, in some degree at least, on which they congratulated themselves that day. They were indebted to the directors for the sagacity with which they had taken the conduct of the affairs; they were indebted to Mr. Gray, the manager, for his business tact and his indomitable zeal and energy; and they were indebted to the secretary and other officials for the interest they had taken in the Company, but behind the directors, the manager himself, and the foremost officials he had mentioned, there were latent forces which they were too apt, perhaps, to overlook and ignore, but which were, nevertheless, absolutely essential to the success of an undertaking such as theirs. The latent forces to which he referred were the workpeople at Silvertown, and it was impossible to say how much they were indebted to them for their sobriety, industry, and skill. He must say that he heartily rejoiced in the suggestion of the directors: he considered it a noble one, and trusted it would be followed by other companies. If employers generally would only show the same spirit of consideration and generosity which was now about to be shown by this Company, the vexed question of capital and labour, which was now agitating the community, would, in his opinion, soon reach a pacific and permanent settlement, and there would, he said, be an indissoluble bond of union established between employer and employed. He had had a great deal to do with working men, and he knew that they were not lacking in gratitude and appreciation. Some years ago it fell to his lot to visit very frequently the works at Silvertown, and he always found the people there ready to receive instruction, and to welcome that highest form of instruction called religious instruction. He heartily welcomed the suggestion of the directors, and trusted ere long that it would develop widely into a scheme which would redound to the credit and honour of the Company.

A SHAREHOLDER presumed that the entire reserve fund was employed in the Company's works.

The CHAIRMAN: The whole is employed in the Company's works. It is all wanted.

The SHAREHOLDER inquired up to what amount it was intended to raise the reserve fund.

The CHAIRMAN: Really we cannot answer that question. As our business increases so must our reserve.

The SHAREHOLDER asked how the reserve was appropriated.

The CHAIRMAN: In whatever is wanted for the works and the business. It is not invested in anything particularly.

The SHAREHOLDER inquired how, in that case, the reserve would be available in case of loss on contracts.

The CHAIRMAN: The whole of our available capital is available for losses. I hope there will be nothing of that sort.

Mr. HANCOCK observed that in their previous accounts they had had the amount shown for profit or loss, as the case might be, on the sale of investments. In the present account, however, the amount was not stated, but as the profit of the half year was large he thought they might naturally conclude that there had been a considerable profit on the sale of investments. He inquired the amount so realised.

The CHAIRMAN: It is not usual for us to disclose where our profits come from. We are a trading company, and I must object distinctly to stating from what sources our profits come.

Mr. HANCOCK repeated that in previous accounts the amount was set out, and as the profits on the sale of investments did not concern those derived from manufacturing, the chairman's reason for not giving the information did not apply. The amount of profits in a year would vary immensely if they were made up of two unknown items—one from manufacturing and the other from the sale of investments. He need not say how much pleasure it gave him to congratulate the Company on the present state of its affairs. Their profits now came to as closely as possible the sum which he (Mr. Hancock) stated, before the company was started, to Mr. John Harvey, the first chairman of the Company, as the profits they might reasonably expect to secure if they had a capital of £250,000 to £500,000. Another great satisfaction to the shareholders, no doubt, would be the fact that in the past year—in fact, for some years past, though more especially in the past year, and there was every probability of it extending—immense ingenuity had been displayed in connection with electric and telegraphic matters. All this would tend to bring them profitable orders, and the progress so far made was likely to be enormously developed. The progress of the telephone and the electric light must, he said, inevitably produce them an increased amount of profit without any particular amount of extra labour, except in the extension of machinery and of the works, the extra profit arising from the orders being four, five, six, or eight times as large as previously. They might, therefore, reasonably conclude that the state of affairs laid before them on the present occasion was one which was likely to be repeated, and in all probability it would improve. He had also been exceedingly pleased with that portion of the report to which a previous speaker had alluded—the appropriation of £6,000 towards furthering the interests of the workpeople. Having had so much to do with workpeople himself, he knew very well the importance of attaching the workpeople to their work, and keeping them as near as possible to

Digitized by Google

their place of work rather than allowing them to wander elsewhere for their amusement and recreation.

Mr. SINCLAIR thought Mr. Hancock's observations called for a few remarks. The directors offered them on the present occasion not only a good dividend but also a good bonus, and he thought they might, without going into the matter very carefully, consider the profits represented by the dividend and the reserve, and the amount carried over by what had been derived from extraneous profits which would, probably, not arise in other years. He thought that that should be remembered. When a dividend of 25 per cent. was paid there were some persons who were very apt to think that they ought to receive the same distribution again. He hoped that they would, but he thought they should be satisfied for the return on their capital which was represented by the dividend only. He joined in the congratulatory remarks which had been made, and he congratulated the management on having brought the Company through its difficulties.

Mr. A. R. JOHNSTON observed that there was no doubt that the dividend of 25 per cent. was a very handsome and gratifying one, but he thought it was only right to draw the attention of the meeting to the fact that the actual profits had been over 60 per cent. As the shareholders received 25 per cent., there was a balance of 35 per cent. remaining, leaving a large margin supposing the profits were not so good in the future. He, therefore, did not think it was right to suggest that they should not look forward again to getting 25 per cent. It was not likely, for instance, that they were going to put by £100,000 every year to reserve fund. The point of his remarks was that they should not depreciate the future prospects of the Company, as had, he thought, been done by the previous speaker.

The CHAIRMAN then put the motion, and declared it carried unanimously. Continuing, he moved the re-election as directors of Messrs. S. W. Silver and Neil Bannatyne.

Mr. JOHNSTON seconded the motion, observing that the gentlemen named had been most energetic in promoting the interests of the Company.

A SHAREHOLDER, however, stated that the task of seconding the motion had been deputed to him. He seconded the resolution with great pleasure. He was one of the directors of the company many years ago, when it was struggling to master its difficulties, and he was glad to know that they had been mastered, and that the progress of the concern had been so decided.

The CHAIRMAN put the resolution, and it was carried unanimously.

Mr. SILVER: It remains for me to acknowledge and to thank you for this evidence of your confidence in us, and to express a hope, and a very strong hope, that we shall continue to preserve the confidence which you have placed in us. We shall do our utmost to deserve it, so that when the time comes we may merit a renewal of it at your hands.

Mr. BANNATYNE briefly endorsed the remarks of Mr. Silver.

On the motion of Mr. H. A. SILVER, seconded by Mr. SINCLAIR, the auditors, Messrs. J. Weise and Abraham Scott, were reappointed for the ensuing year.

The GENERAL MANAGER (Mr. Matthew Gray): I have to put before the meeting this resolution:—"That the directors be and they are hereby authorised to expend out of the funds of the Company a sum of about £6,000 in the erection of a hall and dining rooms on the Company's property." Before I say a word in respect of this resolution let me congratulate the shareholders on the position the Company is now in, and on the handsome profits made from the last year's business. The only reason I refer to that is that I want to warn the shareholders that, although we will do everything we can for them in the future, the past year was an exceptional year. I beg you not to think that it must be repeated—I hope it will be, and often, but I do not want that any shareholder should have an idea that what you receive on the present occasion is what you are always likely to receive. I do not wish to depreciate the property. I have been very ably seconded by all the staff, who work very well for the interests of the Company. As to the workpeople, I endorse the remarks of the gentleman who pointed out that we must not forget that they have aided us in earning the money we have earned. Some of the shareholders may not know it, but about twenty years ago the little works of Mr. Silver were placed in a marsh, the level of the ground being 8ft below high water mark, and the water only kept out by the river wall. We have gone on building works, and houses have been erected in the neighbourhood, but with all the care we have been able to bestow on the place it is not a very desirable locality for any one to live in; and we have had difficulties in getting the workpeople to reside close to the works. It has, therefore, been our desire to make them as far as possible comfortable, and to supply them with proper machinery and well-ventilated rooms. I think the 1,500 workpeople now in our employ are about as comfortably supplied as they can be in the workshops, and as for the appliances inside I do not think I am wrong in saying that they are second to none in London or elsewhere. It has been a work of labour. The work, however, has been done, and I think done well. We ask you now to vote this sum of money, and I do so with a great deal of pleasure. It is needed. Some of the workpeople come from a long distance, and they have no place to go to to have their meals. We want to give them this accommodation, and to provide them with a comfortable place. We, therefore, propose building a dining room for the women and another for the men, where their food can be warmed, and where they can have comfort and shelter in their dinner time. We also propose to build four class rooms, two libraries—a library where the newspapers and books will be handed out by the librarian, and a library where a man can read a book, and smoke his pipe, and make himself comfortable. We further propose building a hall to hold about 600 or 700 people, where lectures and concerts can be given and enjoyed in comfort. The district about there is increasing, and such a place is wanted very much. In anticipation that such accommodation would be provided, we started, some little time ago, the Silvertown Institute, and the teaching has been very successful. Some of the students have been examined at Kensington, and also at Guildhall, and I think they have taken five gold medals, eight silver medals, and several certificates. By and by, when this hall and class room are built, the place will not be handed over to them, but they will get it at a nominal rent, and they will thus have a place where they may combine amusement and instruction close to their work.

Mr. J. O. HANSON seconded the resolution, and it was carried unanimously.

A vote of thanks was then passed to the chairman and directors, and,

The CHAIRMAN having briefly acknowledged the compliment, the proceedings terminated.

THE TELEPHONE COMPANY (LIMITED).

The final meeting of this Company (in liquidation) was held at the City Terminus Hotel on the 26th ult., under the presidency of Mr. Charles Schiff.

The CHAIRMAN said: Gentlemen, it is my duty to report to you now the result of the liquidation of the Telephone Company, and I am happy to say that it has been carried out completely, and with satisfactory results. In point of fact every shareholder of the Telephone Company (Limited) has received one share in the United Telephone Company for every share held in this Company, and as you know the shares of the United Company have been sold as high as 8, 9, or 10. The shareholders have also received two distributions of 10s. each, and I am able to distribute another 2s. 5d. as a final distribution. We have had £9,369 of debts to pay, and the whole cost of the liquidation has amounted to £562 6s. 2d. On the other hand we have received cash, for interest on our deposit pending the liquidation, to the amount of £399 18s. 1d., so that practically the cost of the liquidation has been less than the amount of interest you have earned pending the liquidation. I do not think I have anything more to add, and I shall therefore put this resolution, and after that is passed the cheques for the 2s. 5d. final distribution will be at once forwarded. I beg to move this resolution:—"That the liquidator having laid before this meeting an account showing the manner in which the winding up has been conducted, and its property has been disposed of, resolved, that the same be, and is hereby approved and adopted."

Mr. H. D. BIRD formally seconded the resolution, which was carried, and the proceedings then terminated.

SLIP

German Union Telegraph Company.—The next meeting of this company will take place on March 9.

Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ended 16th instant amounted to £3,824.

To be Wound Up.—A petition for the winding up of the Electric Carbon Company is to be heard to-day (Saturday), before Vice-Chancellor Bacon.

A Contrast.—The cost of taking out an American patent for seventeen years is about £7, whilst in England the same patent would cost about £200 for 14 years.

The Charing-cross Electric Railway.—The Corporation of London have resolved to petition Parliament against the Bill for the construction of this railway.

Electric Lighting in Spain.—The Tarragona, Barcelona, and French Railway Company is about erecting ten Gramme arc lamps to light its principal station.

A New Paper.—*L'Electricidad* of Barcelona is announced as the latest recruit to join the ranks of journalism devoted to electricity. It will be a bi-monthly publication.

"The Electricians' Directory."—*The Electricians' Directory* for 1883 is now published, and may be had from this office, or through any bookseller. The price is 2s.

Gas at Hull.—The British Gas Light Company has reduced the price of its gas supply at Hull to 1s. 10d. per 1,000 cubic feet. Ten years since the corresponding price was 2s. 6d. per 1,000 cubic feet.

Postal Telegraph Appointments.—Mr. J. Donaldson, Telegraph Superintendent at Reading, has been appointed Postmaster at Trowbridge; and Mr. J. Gregson, telegraphist at Rochdale, Postmaster at Workington.

Royal Society.—On Thursday last Mr. W. H. Preece, F.R.S., was to read the following paper before the Royal Society, viz.:—"The Effects of Temperature on the Electromotive Force and Resistance of Batteries."

A Fort Struck by Lightning.—Recent news from the Transvaal states that one of the forts erected for the investment of Mapoch's stronghold had been struck by lightning. One man was killed and 28 men wounded by the flash.

Electric Lighting for Ships.—The Electric Carbon Storage and Apparatus Company have received instruction to light up the ss. "Buninyong," now lying in Sandon Dock, Liverpool, with incandescent and arc lamps throughout.

The Telephone Case.—The solicitors of the United Telephone Company, Messrs. Waterhouse and Winterbotham, deny that Messrs. Harrison, Cox-Walker, and Co. have lodged an appeal in the House of Lords against the recent decision.

Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ending 16th February, 1883, were £2,523, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

Mr. Brush's Storage Battery.—The English patent taken out by Mr. C. F. Brush, through his agent, for a system of storing electrical energy occupies no less than 46 pages of print. The number of the patent is 3108, and it is dated 1st July, 1882. We shall give a brief abstract of it in an early issue.

Savoy Theatre.—A performance of *Iolanthe* was given at this theatre on Thursday week for the special entertainment of the theatrical profession. All the fairies, together with the principal peris, wore electric lights in their hair for the first time. Only a few of the principal fairies had previously worn them.

Electric Lighting on Trains.—The experimental lighting of trains running between Brussels and Antwerp has been put a stop to for a short period, to permit of certain modifications in the plant. It has been found difficult to obtain a sufficiently constant current, and it is with the object of insuring this that the temporary cessation of the lighting has been ordered.

Electric Lighting in Edinburgh.—Messrs. John Mitchell and Son, art furnishers, 106, Princes-street, Edinburgh, have arranged with the Electric Carbon Storage Company, Leith, to have their windows and part of their premises lighted up every evening with incandescent lamps, worked by means of storage batteries, in order to show the effect of the light upon interior decoration, colour, and furnishings.

An Army Telegraph Corps.—Lieut.-Colonel Du Plat Taylor, commanding the 24th (Post Office) Rifle Volunteers, has received instructions from the Secretary of State for War to form an army telegraph corps which might take the field in time of war. The nucleus of this "sister service" to the Army Postal Corps is a company raised principally from the Postal Telegraph Branch, which will be recruited to a strength of 200 rank and file, and supplied with the necessary field equipment.

Applications for Provisional Orders.—According to a report by the Board of Trade on the Bills of the Session, there are 106 applications for provisional orders relating to electric lighting, the capital proposed being £2,752,778. According to the list of provisional orders applied for, given in Vol. X., p. 91, of *The Electrician*, and reprinted in the *Electricians' Directory* for 1883, there were 152 applicants. Comparing this with the Board of Trade report, it will be seen that of this number, 46 have allowed the matter to drop on Mr. Micawber's principle, we suppose.

More Exhibitions.—It is reported that an electric exhibition is to be held in Spain this year, and will open on the 21st December next. The locality is not mentioned by our authority.—An electric exhibition is to be held in Königsberg, in Prussia, and will open on the 15th of April. The committee of organisation includes the names of Dr. Albrecht, director of the Technical School; Dr. Saalschütz, Professor at the University; Herr Sack, councillor; Herr Seidel, director of Telegraphs; and Herr Seydler, apothecary. We believe that the time for sending applications for space has gone by.

Electric Lighting in Sunderland.—A trial of Gülcher arc lamps has lately been made at Lambton Drops, Sunderland, where the operation of loading coal vessels is carried on. The trial has so far been very successful, enabling vessels to be loaded long after dark, or in fact all night long if required. The dynamo, a Gülcher, is driven by one of Tangye's high speed vertical engines. The Gülcher, like the Edison, is a low tension system, and in all cases where ordinary labourers having no knowledge of electricity are liable to come into contact with wires or lamps, this is a consideration.

Digitized by Google

ELECTRIC LIGHTING AND GAS.—The president of the Midland Association of Gas Engineers, Mr. H. Woodhall, of Leeds, is good enough to acknowledge that "the activity and spirit of enterprise which now pervades the (gas) profession," is no doubt due to "their friend the electric light" and its "quickening influence." The public might add that the lowering of gas charges, and the better lighting of the streets in many towns is also due to the same "quickening influence." Gas engineers have been quickened into a trot lately, but they must break into a gallop soon if they do not want to be left behind.

ELECTRIC LIGHTING FOR THE HOUSE OF COMMONS.—It has been stated, says the *Daily News*, "that the use of the electric light is to be extended in the House of Commons, and that the corridors and other parts of the House are to be lighted by the incandescent lamp. On the contrary, the electric light in Palace-yard will henceforward be discontinued. There is a proposal to light the Commons dining room and the library by the incandescent light, but the matter has not gone beyond the stage of consideration." The system in use in the Palace-yard is the Brush. The system proposed for use in the dining room, &c., is, we believe, Edison's.

THE ELECTRIC LIGHT IN SHOPS.—The practical application of electricity to the lighting of shops is being shown on the premises of Messrs. Robinson and Sons' Italian warehousemen, Upperhead-row, Leeds. Two storage batteries are used to feed a series of incandescent lamps, the current to which passes through a number of automatic commutators encased in a box, and by means of which the current is divided, so that it may be carried into distant parts of the building. All risk of accidents from fire caused by a sudden interference with the even flow of the current is removed by plugs, which will, at a temperature of 205deg. Fahr., release the switch of the commutator and secure another, and, under ordinary circumstances, more perfect connection.

A PARADOX.—The Clerkenwell Vestry have had the light given by the Maxim incandescent lamps, which have for some time past been lighting Pentonville-road, tested as to its quantity and quality. Mr. Grimwood, one of the gas examiners of the Metropolitan Board of Works, reported that the lamps in question gave no less than 18 candles more light than was originally stipulated for by the vestry. They wanted 50, and have got 68 candles out of the lamps. Notwithstanding this, however, the special Lighting Committee of the vestry have reported that in their opinion "incandescent lamps are not suitable for out-door lighting." We are not in possession of the full report of the committee, and it is possible there may be something hidden therein which may explain the somewhat paradoxical opinion arrived at by the committee; as it stands, however, we confess to being a little puzzled.

ELECTRIC LIGHTING AND THE FIRE BRIGADE.—An amusing incident occurred on the evening of Thursday week, in connection with some experiments carried on at Messrs. Unwin Brothers' printing office, Little Bridge-street, E.C. At about half-past eight o'clock the neighbourhood was suddenly and brilliantly illuminated by a glare from the first floor windows. A cry of "Fire" was instantly raised, and the neighbouring fire escape and a pair of engines were soon on the spot. The street was thronged with people, but the firemen soon found out they were not wanted. An opposite neighbour, however, was so alarmed that he commenced immediately to move his furniture. The cause of the disturbance was the lighting up of a very powerful "search light," as used by the navy, the carbon of which is 1¼in. in diameter, and capable of giving a light equal to 100,000 candles. This lamp was maintained by a current from an Elphinstone-Vincent dynamo. The effect was splendid, and the crowd who remained greeted the exhibition with an appreciative cheer at the close.

THE INVENTORS OF DYNAMOS.—The following list of the best-known names of inventors of dynamos will be interesting:—Brush, American; Bürgin, Swiss; Edison, American; Elmore, English; Elphinstone and Vincent, English; Ferranti (we do not know Mr. Ferranti's nationality, but we do not think he is English); Gordon, English; Gramme, French; Gülcher, Austrian; Higgs, English; Hopkinson, English; Jablochkoff, Russian; Lumley (the inventor of the dynamo known as the "Lumley" is an American, we believe); Maxim, American; De Meritens, French; Pilsen, Austrian; Schückert, German; Fein, German; Siemens, German; Weston, American; Wilde, English. Reducing this list to numbers, we get the following figures:—American inventors of dynamos number 5, Austrian 2, English 6, French 2, German 3, Russian 1, Swiss 1, and 1 doubtful (Ferranti). Summing up these figures give us 15 foreign inventors of dynamos against 6 English. It says something for England, however, that nearly all these 15 dynamos are to be found in London, and most of them are made there.

ELECTRIC LIGHTING AT LIVERPOOL.—At the meeting of the City Council of Liverpool on Wednesday, a lively discussion was occasioned by a recommendation from the Library Committee to accept a tender for repairing the dynamo which supplies current to the lamps in the Public Library. The sum of £140 was thought to be a great deal for the repair of a dynamo, and it was suggested that whilst the council were about it, they might as well get a larger machine, which would supply current for the lamps in the library, and at the same time to others, which it was suggested should be placed in St. George's Hall. According to a member of the council, it costs a very considerable sum of money to periodically re-decorate the hall, owing to the black deposit occasioned by the present gas burners. It was pointed out, however, by another member, that the money available for St. George's Hall came from a different source to that which was applied to the library purposes. In the end it was agreed that the Finance, Library, and Watch Committees should go into the question and see what could be done.

TELEGRAPH CLERKS' GRIEVANCES.—A large and enthusiastic meeting of telegraph clerks was held at Manchester on Saturday night last. The following resolution was adopted:—"That this meeting desires to record its dissatisfaction with the scheme of revision lately applied to the telegraph services, inasmuch as it fails in many instances to satisfy the just claims of the clerks as set forth in the united petition in 1881, and cannot accept it as a final settlement." The "miserable recognition" by the Government of the services of telegraph clerks was freely commented upon, and the Central Committee were urged to take immediate steps to obtain a parliamentary inquiry into their grievances. It was pointed out that, whilst telegraph clerks in London were paid for their Sunday services, it was "repeatedly and unjustifiably" denied to their provincial brethren. The meeting expressed its gratification at Mr. Fawcett's recovery from illness, and tendered its cordial thanks to him for his earnest endeavours to ameliorate their condition; and also to mem-

bers of Parliament, the Press, and the public for the support which had been accorded to the agitation.

THE TRANSMISSION OF POWER BY ELECTRICITY.—M. Hospitalier thus sums up the results of the Miesbach-Munich experiments of M. Marcel Deprez, in a recent issue of *La Nature*. He says that the experiments established the following fact, viz. :—"Two Gramme machines, type A, identical in every respect, wound with fine wire, can, when the generator exerts an effective mechanical work of 100 kilogrammetres per second (1·33 h.-p.), transport to 60 kilometres distance, over a line of about 1,000 ohms resistance, an effective power of 20 kilogrammetres per second ($\frac{1}{4}$ h.-p.), with a mechanical return of 20 per cent. and an electrical return of 40 per cent." After criticising the arrangement of machines and conducting wire at the recent experiments made by M. Marcel Deprez in the workshops of the Northern of France Railway, of which he was an eye-witness, M. Hospitalier says :—"The experiments made at the Northern Railway will have no meaning until the day when the line is subjected to conditions such as external influences exercise on the elements of the transmission of power of the same kind and the same power as actually occurs under the normal conditions of practical working."

PICTURESQUE ELECTRIC ILLUMINATION.—The electric light has been applied of late in various cases, where the effect has been singularly picturesque. Thus, during a congress of Greek medical men at Athens last year, several electric lamps were placed at elevated points about the Acropolis, and the aspect of the ruins so lit up is said to have been very striking. The Company of Steam Navigation on the Rhine and the Lake of Constance started last year a night service of steamers supplied with Bürgin electric lamps to illuminate the beautiful banks of the river. The steamer left Schaffhausen at fall of night and sailed to Biesingen, and passengers were enabled to enjoy the scenery in those novel circumstances. Further, the falls of the Rhine have been illuminated at night by a powerful electric light placed on the right bank. To appreciate fully the remarkable appearance of the foaming torrent so lit up it is necessary to reach the principal rock, on which is a small pavilion, and where the stream divides into two large parts. Again, there is a regular night service instituted between Cannes and the Lerin Islands, the vessel being the steam yacht "Cannois," which has a powerful Mangin lamp, also thirty-four Swan lamps, arranged between the masts and elsewhere. The electric light guides the course in the difficult navigation which often occurs in these trips and furnishes many lovely views of scenery.—*The Times*.

COMPOUND STEEL AND IRON ELECTRO-MAGNETS.—We take the following from a patent recently issued to Messrs. Ayrton and Perry (No. 3036, dated 27th June, 1882, price 6d.) :—"The first part of our invention consists in the use of a combination of steel and wrought iron in the field magnets of a dynamo electric machine. The steel and iron may be combined together as a tube of steel enclosing a wrought-iron core, or a tube of wrought iron enclosing a steel core, or alternate tubes of wrought iron and steel enclosed within one another, or alternate plates of steel and wrought iron, or any combination of these arrangements. We find that a dynamo machine with field magnets of this kind behaves to some extent like a combination magneto and dynamo machine, and the result is, that with a proper arrangement of winding, at a certain speed, it is possible to obtain a constant electromotive force between the two ends of the outside circuits, whatever be the resistance of the outside circuits; and with other arrangements of winding, and with other speeds, it is possible to obtain a constant current through the outside circuit. In fact, we are able to obtain either constancy of electromotive force or constancy of current, so that whether we work incandescent lamps or motors in parallel circuit, or lamps or motors in series, we get a very large increase in steadiness that enables one motor or lamp to be independent of all the rest."

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—A petition for the confirmation of a special resolution passed by this company for reducing its capital came before Mr. Justice Pearson last week.—Mr. Rigby, Q.C., appeared in support of the petition, and stated that it was not intended in any way to interfere with the rights of creditors. The company consisted of 69,000 shares of £20 each, every one of which had been issued, and every farthing paid up. At the time they were formed into a company they were also concerned in another company, called the Central Company of America, which turned out to be a failure. Money was lent to finance the Central Company, and in 1866 the company was wound up, the sole asset of the company being a telegraph cable somewhere in the Caribbean Sea, which, after examination, turned out to be worthless. The whole of the portion of the capital invested in that company was therefore lost. As the petitioners wished that the share capital should be properly represented, they asked the leave of the Court to reduce their shares to £15, thus striking off one-fourth of their share capital. They further asked that they might be permitted to advertise the amount of the capital of the company as fully paid up, and without the addition of the words "and reduced."—His Lordship said he thought that this was a very honest step on the part of the company to desire that their capital should be properly represented, and not to have it supposed that it was one-fourth more than it really was He should, therefore, grant the application.

ELECTRIC LIGHT WIRES IN INDIA.—"It is somewhat unfortunate for the electric light companies," says the *Times of India*, "that their operations should be impeded by the danger which the presence of their wires causes to the ordinary telegraph wires. Some months ago the Municipal Commissioner of Bombay addressed Government suggesting that the telegraph wires should be so hung as to permit a clear headway of thirty feet to allow for the possible laying of electric light wires throughout the municipal limits of Bombay. Thereupon the local Government referred to the Government of India, which, under date of the 2nd inst., wrote back stating that 'no such general request as that of the Bombay Municipality can be attended to,' as the orders of the Supreme Government require that a clear interval of thirty feet shall be maintained between the wires used for electric lighting and the ordinary telegraph and telephone wires. This, under present circumstances, can be secured in most cases in which the lines are parallel by laying the electric light wires at a sufficient distance from the overhead wires horizontally. There may, however, be cases in the streets of a city in which the interval of thirty feet cannot be secured without raising the telegraph wires or lowering those of the electric light, and in all cases of crossings the Government of India direct that one or other of these alternatives be adopted. Each case must be decided on its own merits, both with regard to priority of occupation of the ground and to the comparative cost of raising or lowering."

ANOTHER IMPORTANT TELEPHONE DECISION.—The long litigation between the Bell Telephone Company and the Dolbear Telephone Company came to an end in the Circuit Court, at Boston, January 24, victory resting with the former. In his decision Judge Gray held :—That Mr. Bell was the

Digitized by Google

first inventor who successfully used the electric current for the transmission of articulate sound. The differences of Dolbear's and Bell's plans are not such as to warrant the former to claim an invention of the entire system. The essence of Bell's invention consists not merely in the form of apparatus which he uses, but in the general process, or method, of which that apparatus is the embodiment. Notwithstanding the distinct difference claimed by the Dolbear receiver, they avail themselves of Mr. Bell's discovery that undulatory vibrations of electricity can intelligently and accurately transmit articulate speech, as well as of the process which Bell invented and by which he reduced his discovery to practical use. They also copy the mode and apparatus by which he creates and transmits the undulatory electrical vibrations corresponding to those of the air. And in the plate charged with electricity, which they have substituted for the magnetic coil in the receiver, the charge constantly varies in accordance with the principle which Mr. Bell discovered, and by means of the undulating current caused by the process and in the mode which he invented and patented. The defendants have, therefore, infringed on Bell's patent by using his general process or method, and should be restrained by injunction from continuing to do so. —*Scientific American.*

Severe Thunderstorm in Zante.—We have received the following from a correspondent in Zante:—The island of Zante was visited recently by one of the most severe thunder and hail storms ever known. The lightning was most vivid, and struck several buildings and trees, both in the town and surrounding country. A large flagstaff, situated on the mole of the Eastern Telegraph Company's quarters, was most beautifully struck. The electric discharge struck the round block at the lanyards, smashing it to atoms. From thence it passed, serpent-like, all down the pole, leaving a splintered groove three inches wide and two deep, right away to the stone-built base, which was split into various pieces by the current in its passage to earth. There is not the slightest trace of fire on any part of the pole, its appearance being rather the result of an axe than of the electric fluid. Several cables run in the immediate vicinity of the flagstaff, but they were in no way affected, nor was it necessary to put the wires to "earth" there, except on one circuit (recorder) for a short time, although the lightning lasted the entire night. Much damage was done by the hail, or, rather, blocks of ice; one piece was picked up weighing fourteen ounces. In one village not a single earthenware tile is intact, and in many places a quantity of large and small birds have been destroyed. Subsequently a violent south-easterly gale sprang up with very heavy seas, and all steamers were three or four days behind their time. It is a strange fact that this island has of late enjoyed a great immunity from earthquake shocks, hitherto of almost weekly occurrence, but, it is to be presumed, nothing will be lost by waiting.

Electric Exhibition at Vienna.—We have received the following additional information with reference to the electric exhibition which it is proposed to hold in Vienna this year. It appears that his Imperial Highness the Crown Prince Archduke Rudolph of Austria has consented to become a patron of the exhibition, and takes great interest in it. His Majesty the Emperor has, through Prince Hohenlohe, given an order to Carl Giani for the production of a very handsome pavilion to be shown at the exhibition. It is intended to drape the interior of this pavilion with rich hangings and embroideries, and to light it up by means of different systems of electric lighting, so as to show the adaptability of the electric light for the purpose, and also to afford a means of comparison between various systems. The extent which the exhibition is likely to reach may be estimated by the fact that the motive power which will be required has been fixed at 1,000 h.-p. About 700 h.-p. is intended to serve for lighting the exhibition buildings and grounds. The boilers and engines employed will, in the majority of cases, be of the fixed type, although portable boilers and engines will not be excluded. All boilers and engines of whatever type will be objects of exhibition. It has been proposed to arrange the boilers and steam engines as they would be if erected for permanent work, and so that they may be easily inspected by visitors. The machinery department will thus offer a good opportunity to engineers of making valuable comparisons. Although such an arrangement will considerably add to the expenses, nevertheless the Commission has consented to sacrifice a greater amount of money in order to secure an opportunity of general instruction, and thus hasten the solution of the important question—how to construct boilers and engines for electric lighting purposes.

A Christmas Card.—We have this week received a copy of a Christmas and New Year's Card for 1882-83, which has been sent us by the officers of the Post and Telegraph Department of Queensland. It is a specimen of one that has been sent, we believe, to all Australian offices. It is very neatly, not to say artistically, got up. It is folded in the centre, and has, therefore, four faces. On the outer face we have photographic coloured views of some chief towns in Brisbane and their post offices, with an elaborate border. Inside we find a list of the chief postal and telegraph officials of the colony. The latter, we may mention here, are Mr. A. F. Matveieff, Superintendent of Telegraphs, and Mr. R. O. Bourne, General Inspector for the Northern District. We also make acquaintance with the following facts, viz., that the colony was established on December 10, 1859; that its population in 1860 was 28,056, and in 1881 226,968; and that the telephone system was established October, 1880. Numerous statistics are given which are interesting, thus we find that the revenue from telegraphs in 1860 was only £938, whilst in 1881 it was £43,940, against an expenditure, in 1860, of £1,652, and in 1881 of £62,124. We may note here that the colony borrowed £439,138 for telegraph construction works in 1881. The number of telegraph offices in 1860 was 7, in 1881 it was 170. The number of messages transmitted and received in the same two years was 6,189 and 661,464, a large increase. Finally, the number of miles of line in 1861 was 169, and there being only a single wire line then, the miles of wire were represented by the same figures; in 1881, however, the miles of line had increased to 6,203, and the miles of wire to 9,089. The back of the card contains what we presume to be an artistic representation of tropical vegetation and a tropical sky, in the centre of which is to be found the greeting and good wishes sent by the Queensland Post and Telegraph Department to their colleagues. We must congratulate the compilers and originators of this Christmas card on their production, and beg to thank them for their good wishes, so far as we are concerned.

Electricity, its Characteristics and Uses. — This was the title of a lecture delivered during the week at Queen-street Hall, Edinburgh, before the members of the Philosophical Institution, by Mr. J. H. A. Macdonald, Q.C., A.S T.E., &c. The lecturer remarked at the outset that electricity was a subject about which we should all soon require

Digitized by Google

to know something practically, because it seemed extremely likely that it would come inside our houses as a practical agent for many useful purposes. It was almost impossible for us, he pointed out, to move about for ten minutes at any hour of the day without bringing electricity into manifestation, and in illustration of this he performed several experiments, in course of which he showed that it was propagated by such simple frictional operations as the brushing of a hat, combing one's hair, and so on. It was explained, however, that the effect of the experiments was considerably neutralised by the damp state of the atmosphere. It was shown that this frictional electricity made an effort to fly off along any substance by which it could escape, and that it could only he imprisoned by the use of substances which would not, easily conduct it; while it was also demonstrated that it rested upon the surface of bodies, consequently the amount of electricity which a body could take up did not depend on the quantity of the material in that body, but on the extent of the surface which it was able to show. Speaking of lightning, the lecturer quoted from the writings of John Wesley to show that the idea of preserving buildings from the action of lightning had occurred to that celebrated divine as early as 1750. After alluding to the other practical methods by which electricity might be got—namely, chemical action, heat, and magnetism—he remarked that these were not exhaustive, because they could get electricity even from animals—there was the torpedo, from which our explosive torpedoes took their name—and no doubt it was also manifested in the growth of plants and in other ways. Altogether the lecture was very interesting. The hall was illuminated by means of 18 Lane-Fox incandescent lamps and one Brush arc lamp, the current being supplied by Faure-Sellon-Volckmar accumulators of the 1 horse-power type. The work was superintended by Mr. F. W. White, of the Electrical Power Storage Company.

New Technical College at Finsbury.—Mr. Philip Magnus, director and secretary of the City and Guilds of London Institute, delivered an opening address in the new Technical College recently erected by the institute in Tabernacle-walk, E.C. There was a large attendance of well-known men of science and others. Amongst them were Dr. Siemens, Dr. Gladstone, Sir F. J. Bramwell, Professors Abel, Ayrton, Perry, and Roscoe, and Sir Sydney Waterlow. The building has been temporarily lighted by the Edison incandescent system. We cannot find room for anything like a full report of Mr. Magnus's address, but we may quote a few sentences with advantage. He said that "considerable misapprehensions still existed as to the importance and possibilities of technical education. Some persons looked to it to remedy all our industrial shortcomings, while others failed to see its advantages or its necessity. Some again referred to science teaching as technical, while others restricted the use of the word to the teaching of an actual trade; the majority of people took a very narrow view of the extension of this term, while others were unable to understand the different kinds of training to which it was applicable. He proposed to call the training, education, or instruction, technical which had direct reference to the career of the student who received it, whether he were engineer, weaver, manufacturing chemist, or cabinet-maker. If he were asked to state in a word what had given rise to the necessity for technical education in the narrower signification of the term, he should answer the invention of the steam engine, as it was to that primarily that we owed production on a large scale, which in its turn had led to the breaking up of the apprenticeship system, thus necessitating some other kind of training. . . . . Every pupil on entering the college would declare to what industry he wished to apply himself, and then he would find a course of instruction drawn out for him on the indicated lines. As it was he thought there were several features in the curriculum of each department of the college which he ventured to think would mark it out as a new departure in educational work, and cause it to rank as intermediate between a school and a college; while the definite course of instruction laid down for each pupil would, if properly pursued, give him a wide and cultivated knowledge of the business to which he meant to devote his energies."

Provisional Orders and the Board of Trade.—An important meeting was held at the Board of Trade on Saturday, of which we take the following account from *The Times*:—"There were present Mr. Farrer, the secretary, Mr. Calcraft, assistant secretary, Captain Armstrong, the electric adviser of the Board; for the Brush Company, Mr. Moulton, Messrs. Webb (solicitors), Mr. Offor (manager), and the company's electric engineer; Mr. Mossop, chairman of the Chelsea Electric Committee, and Mr. Stayton, C.E., their surveyor; Messrs. Dyson for the Metropolitan Board, and the solicitors of St. George's and Mary-le-Strand. Mr. Farrer made a statement as to the general conclusions the Board had arrived at. They wished the local authorities to act for themselves. If two companies applied for the same district the vestry must select the company. The Board would have no bogus companies. The area of supply chosen by the company must be restricted. The company and the vestry agree on the area, and the Board would see that the company had enough means to work the area selected, and the money required must be set aside for that district. As regards the company's profits, and as to any portion of that profit going to the public, the Board would not listen to such a suggestion. The price must be regulated by competition with the gas company, and, if necessary, with other electric companies. Provision for safety against fire must be left to the public, the company, and the fire insurance companies. No meter had yet been found to satisfy the Board; but when one was found it would be introduced. Model clauses would be prepared by the Board and issued to the public in a week's time to promote uniformity. It was stated that the President did not interfere because Birmingham was so largely interested in the subject.—Mr. Mossop cordially approved the proposed conditions, but suggested that the Board might be so stringent that the parish would get no electric light. The companies were entitled to a fair profit.—Mr. Moulton was glad to find that the vestries were not the ogres they had been represented to be. He contended that besides the limited area A the companies should have a much larger area B. It was the company who had to experiment, and they ought to profit by their own experience.—Mr. Mossop said the argument simply meant that the companies were to go on learning, and the rest of the world was to rest and be thankful.—Mr. Farrer said they must agree as to their areas with the vestries. The same provisions would apply to schedule B as to A as to money and so on. Mr. Farrer pointed out that if a company went into a parish and took the cream of it and neglected the rest of the parish the Board would have power to take away some of the cream and give it to another company willing to light the poorer district.—Messrs. Dyson asked what was to be done in those cases where the vestries had determined to oppose the provisional order *in toto*?—Mr. Farrer said the parishes could reconsider that matter when the model clauses were before them."

CURRENT ENERGY.—II.

BY OLIVER HEAVISIDE.

Given two closed circuits of any form with steady currents in them, placed at any distance apart in any relative positions, we have found (p. 223 *ante*) that the mechanical force between them may be completely defined by the variation of a certain quantity, M, which has a definite value for every configuration. Any linear displacement dx of one conductor, moving as a whole without rotation, is assisted by a real force arising from the mutual action of strength $-\frac{d\mathrm{M}}{dx}$, or the rate of decrease of M per unit displacement; and, extending the meaning of a displacement to signify any small change of position, and at the same time generalising the meaning of force so that its definition shall be contained in the statement "force × displacement = work done by the force during the displacement," we have the same relation, force $= -\frac{d\mathrm{M}}{dx}$.

This expression of the force as the variation of the quantity M is simply a reversal of the statement that M is the integral of the force. For the method of obtaining M is entirely founded upon the fact that the mechanical force between two conductors bearing currents is the same as that between two magnetic shells of the same strengths as the currents, and with coincident edges, which again is reducible to forces acting according to the law of the inverse square of the distance between quantities of magnetic matter, so that M is really the mutual potential energy of the distribution of matter. We may also say that M is the mutual potential energy of the currents, remembering, however, that the currents must not vary; for our equivalent magnetic shells are rigidly magnetised, and we so far ignore the existence of changes in the currents produced by the relative motion of the circuits.

The quantity M for the complete circuits is the same as if any pair of current elements of strengths C and C′ and lengths ds and ds', at distance r apart, one being in the first and the other in the second circuit, contributed the amount $-\overline{\mathrm{CC}}'\frac{ds\,ds'}{r}$, (equation (5) p. 225). From this we may see how the energy and the forces are affected by changes of dimensions in similar systems. For let there be another pair of circuits similar to the first, of n-fold linear dimensions, and similarly situated, so that every line joining corresponding points is magnified n times; divide the circuits into the same number of elements of length as the first pair, thus making each element n times as long; then $\frac{ds\,ds'}{r}$ is multiplied $\frac{n\times n}{n} = n$ times. Hence if the currents are the same in both cases, the energy is n times as great in the magnified system.

As for the forces, they are quite unaltered. For if dx be a displacement in the first case, it becomes $n\,dx$ in the second; and the changes in M corresponding are $d\mathrm{M}$ and $n\,d\mathrm{M}$. But the force is the change in M per *unit* displacement, and is therefore simply $d\mathrm{M}$ as before. Thus, in similar linear systems with the same currents, the forces are independent of, and the energy varies as the linear dimensions. [The law, force in similar systems unchanged, was made one of the bases of Ampère's theory, as an experimental fact; from it follows, that if the actually observed actions were due to mutual forces between the different parts of the two conductors or currents, such forces must vary as the inverse square of the distance, when the inclinations of elements are the same. This, of course, also follows from $\frac{ds\,ds'}{r}$; its rate of decrease along r being $\frac{ds\,ds'}{r^2}$.]

In varying the linear dimensions we kept the currents constant, so that it did not matter whether we varied the *sections* of the conductors or not. But, varying all the linear dimensions, if we keep the current densities constant, so that with a doubled sectional area we have a doubled current, then, since an n-fold increase of linear dimensions multiplies each of the sections n^2 times, the currents are made n^2 times as great; hence in the magnified system the energy is multiplied $n\times n^2\times n^2$, or n^5 times instead of only n times, whilst the forces are multiplied n^4 times.

This law of the fifth power, which in its application to dynamos has been pointed out by M. Marcel Deprez, is a particular case of a more general law. The potential energy of any similar distributions of matter with the gravitational law of inverse squares varies as the fifth power of the linear dimensions and as the squares of the densities. (Thomson, "Electrostatics and Magnetism," p. 435). The matter may be of the electric or magnetic kind, repulsion between like, and attraction between unlike kinds. If ρ is the volume-density and P the potential, $\frac{1}{2}\Sigma\mathrm{P}\rho$ is the potential energy, the summation including all the matter. Here $\mathrm{P} = \Sigma\frac{\rho'}{r}$ as usual; hence the energy $= \frac{1}{2}\Sigma\Sigma\frac{\rho\rho'}{r}$, where ρ and ρ' are the quantities of matter in any two elements of volume and r their distance apart. Now, in a system of n-fold dimensions, divided into the same number of elements of volume, each of them is n^3 times as large, and their distances apart are all multiplied n times; hence the energy is multiplied $\frac{n^3n^3}{n} = n^5$ times. And, of course, when the density varies, the energy varies as its square, since ρ and ρ' are both similarly increased.

But applying this law to similar magnets of different dimensions, but of the same *intensity of magnetisation*, at corresponding places, the law becomes that of the cube, not of the fifth power. This may be easily seen by comparing two similar magnets, solenoidally magnetised. If their intensities of magnetisation are the same, the surface densities of free magnetism are the same. But the law of the fifth power applies to *volume* densities, hence there is a loss of two dimensions. Or, replace the surface-density, say σ, by a volume density $\frac{\sigma}{t}$, t being the small thickness of the layer. An n-fold increase of linear dimensions with volume density constant would increase the energy n^5 times as before; but then, since t would be multiplied n times, σ would experience a like increase to keep $\frac{\sigma}{t}$ the volume-density constant; consequently, the intensity of magnetisation, which is numerically the same as the surface density, would also vary as the linear dimensions. Thus, with the intensity of magnetisation kept constant, an n-fold increase of linear dimensions of a magnet makes the volume-density (replacing the surface-density) vary inversely as n. Hence, remembering that the energy varies as the square of the volume-density, we have the energy multiplied only $\frac{n^5}{n^2}$ or n^3 times.

Yet, although the n^3 law holds for magnets with intensity of magnetisation constant, it does not hold for current systems, with the density of current kept constant, even when we replace the currents by magnetic shells producing the same fields of force. For the strength of the equivalent shell in any case is its intensity of magnetisation multiplied by its thickness, and the strength must be numerically equal to the strength of the current it replaces. Now, the latter varies as n^2 with constant current-density; hence, if the thickness of the shell becomes n times as great in the magnified system, its intensity of magnetisation or the surface-density must be also multiplied n times to keep pace with the current it replaces. Thus we have the case of similar magnets whose intensities of magnetisation vary as the linear dimensions, or of similar distributions of matter of contstant volume-densities, and therefore the n^5 law holds. [I observe, however, that Sir W. Thomson, in the paper above referred to (on p. 435) makes the cube law hold both for magnets ("polar magnets") with constant intensities of magnetisations, *and* for

Digitized by Google

current systems ("electro-magnets," or systems of magnetic force due entirely to electric currents) with constant densities of current (or "intensities"). This may be a slip, or I may not catch the meaning correctly, or the n^5 law may not apply to currents as it appears to do.]

As regards the *magnetic* force in similar systems of current, since at a point P it is the sum of $\frac{Ch}{r^3}\,ds$ for each element of a linear circuit (p. 177. *ante*), r being the distance of P from the element, and h its distance from the axis of the current, h, r, and ds are all multiplied n times in a system of n-fold linear dimensions with the same integral current C in corresponding places; the magnetic force is therefore multiplied $\frac{n.n}{n^3}$ or $\frac{1}{n}$ times, and thus varies *inversely* as the linear dimensions. But under the same circumstances, with density of current constant, so that C varies as n^2, the magnetic force varies as $\frac{n^2}{n}$ or n, *i.e.*, *directly* as the linear dimensions.

Now, the energy is expressible, as will be seen later, also in the form $\frac{1}{8\pi}\Sigma$ (force)^2, the summation being extended throughout all space. Here (force)^2 varies as n^2 under the last-mentioned circumstances, and the volume as n^3; hence we obtain the n^5 law again with density of current constant.

Leaving now the question of dimensions, let us pass on to the more general case of the mutual energy of two arbitrary current systems. If we have a closed linear current C in presence of any number of others, C′, C″, &c., we know exactly the value of M for our selected circuit C, and any one of the others, say C′, if the rest of the system were non-existent. It is numerically C × amount of magnetic force through it due to C′, or *vice versâ*. Also, − M is the amount of mechanical work that would have to be done by external force against the electro-magnetic forces to separate C and C′ from their actual positions to an infinite distance apart, keeping the currents constant. Now, this being the case for C and C′ alone, and for C and C″ alone, when C′ and C″ exist together, the mechanical work required to remove C is simply the sum of the amounts of work done separately in the former cases. It is, indeed, obvious that the amount of magnetic force that C′ and C″ when co-existent send through C is the sum of the amounts they would separately send through C; and that the corresponding proposition is true for the work done follows from the mutual nature of the mechanical forces between the conductors, and is most easily seen to be true by replacing the currents by magnetic shells, by which we are reduced to mutual forces between sets of attracting or repelling points. In the case of the current, we may either remove C, fixing C′ and C″, or fix C and remove C′ and C″, or remove both C and the pair; but the pair must move as a rigid body without relative motion; or, if there be any, it must be cancelled later. And, in general, the energy of C with respect to any current system is the sum of its energies with respect to the individual members of the system. And here remark that we have no concern with the mutual energies of the members of the system amongst themselves.

This being true for one closed current in presence of a system, is true for a second, or for any number; and, therefore, we have the result that the mutual energy of two arbitrary current systems (arbitrary in all except that they must consist entirely of closed currents) is the sum of the mutual energies of all the pairs that can be made, taking one member of a pair from one system, and the other from the second; and, since in neither system are we concerned with the internal energy, their mutual energy is the work to be done to bring them together to their actual positions moving as rigid bodies, without internal relative motion; or, if there be such, we must not count work so performed.

For the expression of this and other results in a simple manner, it will be convenient to introduce volume-elements of current, instead of the linear elements previously used. If we have a current in a wire, and consider the latter as a mere line, we have, of course, infinite concentration of current. There is no appreciable error caused by replacing wires by lines so long as the wires are not very close together, and there will be no error if we locate the lines properly; but when we are considering currents in general, it is best to take things as they are, viz., finite currents across finite areas.

A current system may be split up into tubes of flow, which are all closed. Any tube is independent of the rest, in so far that there is no current from it to its neighbours, for it is bounded by lines of flow. Now, by splitting up the tubes into an indefinitely great number, we at the same time reduce their sections indefinitely, and also the currents they carry; hence in the limit we may treat every current-tube as a closed linear circuit carrying an infinitely small current. Let ds be an element of length of such a tube, dS its section anywhere, then $ds\,d$S is an element of volume, say, dV. Let, now, C be the current density, *i.e.*, C dS = current crossing dS, so that C would be the current across unit of area normal to the current were its density all over the unit area the same as at dS. Now, our linear element (p. 225) was integral current × element of length; this now becomes (C dS) ds or C dV. Further, we may conveniently take the element of volume to be the unit volume, since the latter may be as small as we please. We now have, instead of equation (5) (p. 225), the following:—The mutual energy of two closed currents is the same as if every pair of unit volumes, one belonging to the first, and the other to the second circuit, contributed the amount

$$-\frac{1}{r}\,\overline{\mathrm{CC'}} = -\,\overline{\mathrm{AC'}} = -\,\overline{\mathrm{A'C}} \quad . \quad . \quad . \quad (1)$$

Here, A = C ÷ r, is the vector-potential of C at C′, and A = C′ ÷ r is the vector-potential of C′ at C, r being their distance apart.

Now, applying (1) to two arbitrary current systems. We know that (1) is true when summed up for two closed tubes of indefinitely small section, and that our systems may be split up into such tubes. It follows that when we divide space into elements of volume (ignoring the tubes completely), and apply (1) to every pair of volume elements that can be made between the two systems, and sum up, we shall obtain the mutual energy, for as soon as we have finished the summation we have closed all the tubes.

Therefore, the mutual potential energy M of two systems of densities, C and C′, is

$$\mathrm{M} = -\,\Sigma\Sigma\frac{1}{r}\,\overline{\mathrm{CC'}} = -\,\Sigma\,\overline{\mathrm{AC'}} = -\,\Sigma\,\overline{\mathrm{A'C}}. \quad . \quad (2)$$

when A is the complete vector-potential of the first, and A′ of the second system. In one form we have a double summation, viz., to all pairs of current elements; in the other forms there is but one summation, because the vector-potential itself is obtained by a summation. Thus, in the form of $-\,\Sigma\,\overline{\mathrm{AC'}}$, we sum up $\overline{\mathrm{AC'}}$ for every element of the second system; here A expresses a summation over the first system, viz., $\Sigma\frac{\mathrm{C}}{r}$ (vector sum).

Corresponding to (2) these are exactly analogous expressions for the mutual energy of two systems of electrification, and the comparison is instructive. ρ and ρ' being the volume-densities of free electricity, P and P′ the potentials, and M the energy, we have

$$\mathrm{M} = \Sigma\Sigma\frac{1}{r}\rho\rho' = \Sigma\,\mathrm{P}\rho' = \Sigma\,\mathrm{P'}\rho \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Here ρ, the density of electrification, corresponds to C, the current density in (2), and P the scalar potential to A, the vector-potential. Both ρ and P are scalars, and their product is found as in algebra. But in (2) both the currents and their potentials are vectors, which is how it comes about that we have to multiply by the cosine of the angle between their directions, indicated by the stroke. As for the negative sign in (2) and positive in (3), it arises from similarly directed currents attracting, whilst similar electrifications repel.

[The following rule is useful in adding the scalar products of vectors. If A_1, A_2, A_3 . . . are any vectors whose vector-sum is A, and C is any other vector, then—

$$\overline{\mathrm{A}_1\mathrm{C}} + \overline{\mathrm{A}_2\mathrm{C}} + \overline{\mathrm{A}_3\mathrm{C}} + \ldots = \overline{\mathrm{AC}}.]$$

SOME EXPERIMENTS IN THE TRANSMISSION OF POWER BY ELECTRICITY.*

BY GEORGE AND WILLIAM C. GIBBS.

Description of Generator and Motor.

The dynamo-electric machine used as a generator was one of Mr. Weston's latest pattern, known as the "fifty light incandescent machine." The machine used as a motor was identical with the preceding, except that it was only intended to run forty lights.

The machines were of the derived field type, that is, the field magnets were wound with comparatively fine wire, so that their resistance was about 800 times the resistance of the armature. The terminals of the field wire were connected with the brushes directly, and, therefore, when the machine was running, the magnets became charged even if the main circuit was not closed.

In this machine the magnets are horizontally arranged above and below the armature. They are essentially two horse-shoe magnets with like poles turned toward each other. The armature is wound with a continuous heavy wire, which is brought out at every turn into a loop and soldered to the commutator.

The core of the armature is made up of thin wrought-iron discs separated by small washers of gelatinised fibre. The discs are shaped somewhat like a gear wheel, that is, they have teeth on the edge to the number of perhaps twenty, and of the width of one-fourth of an inch, so that when the armature is complete there are a number of ridges running its whole length parallel to the axis. In the hollows between the ridges is wound the wire of the armature in a single layer, which, when finished, is of the same height as the ridges, making the whole a true cylinder. The ridges are called "polar extensions," for by projecting through the layer of wire they come very near to the field magnets and increase the polarity of the armature when the machine is running, and consequently the intensity of the lines of magnetic force. The core is, moreover, pierced from end to end with several holes arranged at equal angular distances apart, and the discs of which it is made up being separated from each other by the space of about a twentieth of an inch, a complete system of ventilation is kept up by the action of the machine, and the armature is thus kept cool. Each disc has also two radial slots cut in it to prevent the formation of an extra current. The commutator is composed of copper sectors separated by gelatinised fibre strips.

The brushes are of silver plated copper, each brush being composed of several strips, placed on one another, so that although the brush has great flexibility it has also sufficient springiness to cause it to press uniformly on the commutator.

Each brush is, besides, held in a spring clamp, which yields to any inequality of the commutator. The brushes are adjustable at any angle about their axis, and are in practice turned to the point of least sparking, which is the neutral plane of the machine. When properly adjusted the sparking is inappreciable.

The wire from each pair of field magnets terminates at a binding post on the top of the machine. When the generator is working to its full capacity these posts are connected by a short wire, but when it is desirable to use any part of the power of the machine, a variable resistance is placed between them. By altering this resistance the intensity of the magnetic field is varied, and the work done may be perfectly controlled. The resistance of the armature was ·03 ohm, and the resistance of the field was 24·5 ohms, measured while warm, immediately after the experiments ceased.

Description of Dynamometer.

In measuring the power to be transmitted from the engine to the generator, the Kent dynamometer built by the class of '76 of the Stevens Institute was used. In this dynamometer the receiving and transmitting pulleys are each carried by a separate shaft. These shafts are in the same straight line, and upon the ends which face each other there are two bevel wheels. A third bevel wheel at right angles to these two connects them and transmits motion from one shaft to the other. This wheel is loose upon its axis, which is prolonged to form a pendulum, and is supported by a brass pin passing through it and fitting into holes in the transmitting and receiving shafts. A heavy weight is attached to the end of the pendulum, and when the machine is running the pendulum is deflected from the normal vertical position to a position approaching more or less the horizontal.

The sine of the angle of deflection, the weight of the pendulum and "bob," and the number of revolutions per minute determine the power transmitted.

The dynamometer was standardised as follows:

The pendulum was supported in a horizontal position by a prop at a distance of two feet from the centre of the pin connecting the shafts. The lower end of the prop rested on a platform scale.

The weight indicated was 170·5lb., and since the lever arm of this weight is divided by two, by the arrangement of gear wheels above described, the weight at *one* foot is 170·5 pounds.

Then to get the power transmitted we have,

$W = 170{\cdot}5 \times \text{sine } \theta \times (6{\cdot}28 = 2\pi) \times$ number of revolutions.

Where W = work done in ft. lb. per min.

Of this power, however, a certain percentage is lost in overcoming the friction of the bearings, and must be allowed for.

To find the friction, the main and field circuits of the generator were broken, but the brushes left on the machine. A 7in. pulley was fastened on the shaft of the generator, close to the 12in. driving pulley. On the small pulley a prony brake was arranged, so that when the engine was transmitting power to the generator through the dynamometer the energy absorbed by the brake was substituted directly for the electrical energy developed by the machine when the circuits were closed.

Several experiments were made at different deflections of the pendulum.

The variation was not great, but the mean is given.

The speed was constant, and was the same as in all the experiments on the efficiency of generator.

Dynamometer:

Sine of deflection = ·33.
Weight = 170·5lb.
Radius of driving pulley = 16in.

Therefore the constant pressure indicated $= \frac{170{\cdot}5 \times {\cdot}33}{1{\cdot}33} =$ 42·3lb.

Prony brake:

Length of arm = 30in.
Pressure on scale = 7·25lb.

Pressure at circumference of pulley $= 7{\cdot}25 \times \frac{30}{6} = 36{\cdot}25$lb.

Since the dynamo pulley is 12in. diameter; $42{\cdot}30 - 36{\cdot}25 = 6{\cdot}05$ = loss by friction, and $\frac{6{\cdot}05}{42{\cdot}3} = 14{\cdot}2$ per cent. friction.

Fricton of Armature Bearings.

Lack of suitable apparatus prevented us from determining this experimentally, but since it has been found for similar machines by repeated experiment to be less than 3 per cent., and since the bearings in the machine used were as nearly perfect as skilful workmen and accurate mechanical means could make them (being a steel shaft running in gun metal bearings), we felt at liberty to assume the friction as 2·5 per cent. The bearings were oiled by continuous oilers, and the heating was so small as to be imperceptible even after long runs.

Efficiency of Generator.

In making tests for the efficiency of the generator, the current generated was carried by iron wire resistances running across the room from side to side in the open air, so that the heat generated was rapidly conducted away.

* Abstract of a Thesis written at the Stevens Institute of Technology. [This abstract has appeared in *Van Nostrand's Journal*, a specially corrected proof being sent to us by the authors.—ED. *E.*]

Digitized by Google

A switch was so arranged that the generator could be instantly thrown out of circuit and the resistance of the line measured within five seconds. In this way the varying effect of temperature on the resistance was eliminated.

All resistances were measured by a Thomson high-resistance galvanometer. An electric lamp placed in a magic lantern threw a ray of light on the galvanometer mirror, which was reflected to a screen. This gave an immensely magnified motion to the image, so that the scale could be read from some distance in a well-lighted room.

Calorimeter Test.

In determining the electrical energy developed by this method a calorimeter was used in circuit with the iron wire resistance.

This calorimeter consisted of a cylindrical vessel of galvanised iron imbedded in sawdust in a wooden box. By this means any great waste of heat by conduction and radiation was prevented; but as some heat must have been conducted by the wood, it was allowed for in each case by taking water at the atmospheric temperature and cooling it by means of ice to as many degrees below that temperature as it was to be raised above it by the heating of the coil. In this way the transfer of heat from the sawdust to the water during the first half of the experiment was equal to the transfer from the water to the sawdust during the second half. The electrical energy expended in the calorimeter was measured by its heating effect on a coil of German-silver wire. The wire used in the coil was of No. 8. B. W. G.

The coil itself was entirely immersed in the water, and its ends were soldered to two copper rods which were fastened in the calorimeter cover. In this way the high resistance wire being entirely under water, any over-heating was prevented. The resistance of the coil was exactly ·09 ohm at 74° Fahr. in the water.

Distilled water was used in the calorimeter, it having a much higher resistance than ordinary water, thus diminishing the tendency of the current to pass through the water from one turn of the coil to another. No evidence of such an action having taken place was, however, observed at the conclusion of the tests.

An uniform temperature of the water in the calorimeter was secured by using two miniature screw-propellers of wood, which were constantly turned in the water during the experiments.

When everything was ready for the test the generator was run until the circuit was thoroughly heated, and its resistance remained constant.

The calorimeter was then thrown into the circuit and an equal resistance of circuit thrown out, so as not to alter the total resistance. At the end of the test the resistance was measured as soon as the circuit was broken and before the wires had cooled.

Data from this test.

Weight of calorimeter empty, 31 pounds.
Weight of calorimeter full, 58·25 pounds.
Weight of water in calorimeter, 27·25 pounds.
Range of temperature, = 91·2° = 68·6° = 22·6° Fahr.
Specific heat for above range, = 1·018.
Time of test, = 25 minutes.
Resistance of iron wires and calorimeter coil, = ·484 ohm.
This resistance and field in multiple are = ·475 ohm.
Total resistance of circuit, = ·475 × ·03 = ·505.
Resistance of calorimeter coil, = ·09 ohm.
Ratio of resistance of total circuit to resistance of calorimeter coil, $= \frac{\cdot 505}{\cdot 09} = 5{\cdot}61$.

Results.

Energy developed in calorimeter =

$$\frac{27{\cdot}21 \times 1{\cdot}018 \times 22{\cdot}6^\circ \times 772}{25} = 19330{\cdot}89 \text{ft.-lb. per minute.}$$

Total electrical energy developed in circuit,

$$19330{\cdot}89 \times 5{\cdot}61 = 108446{\cdot}28 \text{ft.-lb. per minute.}$$

Determination of the energy transmitted by the dynamometer in this test:

Speed of dynamometer, = 340 revs per min.
Sine of the angle of deflection, = ·36.

Therefore, indicated energy =

$$170{\cdot}5 \times {\cdot}36 \times 6{\cdot}28 \times 340 = 131056{\cdot}4 \text{ft.-lb. per min.}$$

Determination of the efficiency of generator from the above:

Energy consumed in turning armature in field of force =

$$131056{\cdot}4 \times {\cdot}858 = 112446 \text{ft.-lb. per min.}$$

$$\therefore \text{Efficiency} = \frac{108446{\cdot}28}{112446} = {\cdot}963.$$

That is, 96·3 per cent. of the power applied to the armature pulley appears as electrical energy in circuit and magnet coils.

Now, to find the "commercial efficiency," or the ratio of the mechanical energy required to drive the dynamo (including friction of armature bearings and agitation of air by armature) to the electrical energy which appears in external circuit, we have:—

Energy actually applied to armature pulley = total indicated energy less the friction of the dynamometer = 131056·4 × ·883 = 115722·8 ft.-lbs. per min. Of the total electrical energy generated there appeared in the armature

$$- 108446{\cdot}28 \times \frac{\cdot 03}{\cdot 505} = 6442{\cdot}35 \text{ ft.-lbs.}$$

And the electrical energy consumed in the field circuit, which appeared partly as heat and was partly used in magnetising the cores $= 108446{\cdot}28 \times \frac{505}{24{\cdot}51} = {\cdot}02 \times 108446{\cdot}28$ = 2168·92 ft.-lbs. per min.

Then the total internal work = 2168·92 + 6442·35 = 8611·27 ft.-lbs. per min.

Therefore the amount of energy appearing in external circuit = 108446·28 − 8611·27 = 99835·01 ft.-lbs. and the commercial efficiency $= \frac{99835{\cdot}01}{115722{\cdot}8} = {\cdot}866$.

Tests by Measurements of the Electromotive Force and Resistance.

In order to determine the electrical energy by this method, we first measured the electromotive force of the machine and the resistance of the line very accurately. From these data we found the current flowing by the formula $c = \frac{E}{R}$. Then, knowing the current, the electrical energy developed in external circuit is given by the following empirical formula $-c^2 R \times 44{\cdot}24$ = energy in ft. lbs. per min.

The electromotive force was measured between the binding posts of the generator by means of a condenser and a Thomson high resistance galvanometer.

The standard of electromotive force employed was the Latimer Clarke cell. Two of these cells were obtained newly made up from the Western Union Telegraph Company. They were allowed to charge a microfarad condenser, and the condenser was then discharged through the galvanometer. A number of experiments were made with these in order to determine accurately the deflection on the scale corresponding to a cell. This deflection is proportional to the current flowing through the galvanometer coils, and, consequently, of the charge held by the condenser, which depends upon the electromotive force of the charging cell.

The deflection corresponding to one cell was found to be exactly five divisions of the scale. Elliott Brothers' switch was used to connect the dynamo and galvanometer alternately with the condenser.

The connections were made as perfect as possible by amalgamation.

Data.

Capacity of condenser = ·05 microfarad. Deflection o

Digitized by Google

galvanometer with condenser charged by cell = 5 divisions. Average deflection of galvanometer with condenser charged by dynamo = 103·5 divisions. Electromotive force of cell = 1·457 volts.

Therefore, 5 : 1·457 : : 103·5 : (x = 30·159 volts). Resistance of line while hot = ·431 ohm. Since the electromotive force was measured between the binding-posts the resistance of the armature was excluded.

Resistance of armature = ·03 ohm.

∴ Resistance between binding-posts = ·401 ohm.

Then $-c = \frac{E}{R}$.

$$c = \frac{30·159}{·401} = 75·2 \text{ webers.}$$

Energy developed in external circuit

$= c^2 R \times 44·24 = (75 : 2)^2 \times ·401 \times 44·24 = 100330·8$ft. lbs. per min.

Total electrical energy,

$$100330·8 \times \frac{·431}{·401} = 107352·95\text{ft. lbs. per min.}$$

Energy indicated by dynamometer,

Sine of mean deflection = ·352

Mean speed = 340 revs.

Indicated energy,

$170·5 \times ·352 \times 6·28 \times 340 = 128306$ft. lbs. per min.

Applied energy (equal total energy minus combined friction) = 128306 × ·868 = 110087 ft. lb.

Therefore, efficiency of machine $= \frac{107352·95}{110087} = ·975$ or 97·5 per cent. actually appeared as electrical energy in external and field circuits.

Determination of the commercial eff.

Energy actually applied to armature pulley—

$$128306 \times ·883 = 113294·19 \text{ ft. lb. per min.}$$

Of this there appeared in the armature—

$$107352·95 \times \frac{·03}{·431} = 7472·35 \text{ ft. lb. per min.}$$

And in the field circuit—

$$107352·95 \times \frac{·431'}{24·51} = 1887·76 \text{ ft. lb. per min.}$$

Therefore, total internal work =

$$7472·35 + 1887·76 = 9360·11 \text{ ft. lb. per min.}$$

Then there appeared in external circuit—

$$107352·95 - 9360·11 = 97992·84 \text{ ft. lb.}$$

And commercial efficiency =

$$\frac{97992·84}{113294·19} = ·864.$$

The resultant efficiency of the generator will be the mean of the two efficiencies as determined by the two methods, or;

Average efficiency = ·969,

Average commercial efficiency = ·865.

Efficiency of Motor.

In determining the efficiency of the motor as a machine for converting electrical energy into mechanical, we connected the generator and motor by heavy copper rods in order to reduce the loss of energy in the line to a minimum. A prony brake was applied to the pulley of the motor and the pressure of its arm upon a platform scale measured directly. This gave an accurate indication of the power of the motor.

To avoid heating of the brake by friction, it was arranged in such a manner that a stream of cold water entered it at the top, and after passing through it to the pulley, escaped by a hole in the bottom. In this way we were enabled to make runs of any length of time. Between the nuts which tightened the brake, and the brake itself, were placed thick rubber washers, which by their elasticity yielded to any inequality of motion, and kept the speed and corresponding pressure on the scale very constant.

By means of the brake we could apply variable loads and get various ratios between the speeds of the two machines.

The electrical energy entering the motor was controlled by altering the variable resistance in the field of the generator.

Although this alteration diminished the intensity of the magnetic field, the work done in the coils did not vary until after the third decimal place, so the commercial efficiency of the machine remained constant.

The conditions, however, having been altered, the results are not such as can be plotted in a curve.

It is to be remarked that in these experiments the machines which we used were so large that it was not possible to work them up to their full capacity, the dynamometer being unable to transmit sufficient power.

The results obtained are tabulated as follows:—

Dynamo.

Efficiency of Motor.

The motor, as a machine for converting electrical energy

Digitized by Google

into mechanical, seems to be excellently adapted to the purpose. The only point that admits of improvement is probably the resistance of the magnet coils, which should be higher in proportion to the resistance of the armature, thus taking less current to keep up the magnetic field.

Efficiency of the Combination.

It is when the generator and motor are coupled together that the efficiency of the whole falls, as is shown by the tables, to such a low percentage.

The reason for this, however, and the means of remedying it seem obvious.

By one of the fundamental laws of electricity, we know that the work done in any portion of an electric circuit is directly proportional to its resistance.

In the case of the two machines coupled, as in the above series of experiments, the resistance of each was very low and equal, while the resistance of the line was practically nothing.

Under these conditions, nearly half the work must necessarily be done in the generator, and the results verified this law.

In order then to increase the efficiency of the combination, more work proportionally must be done in the motor and less in the generator. To accomplish this, we find by applying the above rule that one of two things may be done—we may either decrease the resistance of the generator or increase the resistance of the motor. In practice, a compromise would probably be made, that is, the generator armature would have its resistance reduced, and the motor have the resistance of its armature raised sufficiently to cause nearly all the work to be done in the motor.

This applies to a single motor.

Where several motors were supplied with current from a single machine they would probably be arranged in "multiple arc," and be of such a resistance that they would take only a certain amount of current, and, when coupled up with the generator, their resulting resistance would be the same as would be given to a single motor doing the combined work of all.

In this way each machine does in a measure induce its own current and controls the current generated, so that if only one motor is running, the current generated is only sufficient for it, and as each one is put in circuit the current increases in a ratio which just keeps each motor supplied with the proper amount of current.

When by a course of experiment the proper ratio of resistances shall have been determined, there seems to be no reason why the combined efficiency should be below 80 per cent.

THE ACTION OF THE MICROPHONE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Smillie's suggestion (p. 208) that the resistance of a transmitter in vacuo is diminished by extracting the air from the pores of the carbon is fallacious, for the reason that the carbon forms a continuous structure, and the pores formed by this structure might be filled with paraffin without altering the resistance, provided a good surface contact is made by dissolving the paraffin on the outside, or scraping it off. He further says he cannot conceive two bodies in contact and a third between. Certainly not. But I pointed out that a loose contact may not be a contact at all, and this conception is, I think, easily within the reach of probability.

Truly, the admission of an intervening air space is "favourable" to the arc theory, but the arc is not a necessary consequence. But supposing by a proper increase of pressure on the "loose" contact we produce a "real" contact, this would not do away with the air layer when the contact changes under the vibration of the voice.

I hope soon to continue the experiments with a Sprengel or Geissler pump, which thus far I was not fortunate enough to have at my disposal, and I have no doubt that in "high" vacuo, where the condensed air will disappear from the carbon surface, the character of the sound produced by vibrating the contact will be similar to a true "metallic" contact.

In the meantime the practical telephonist will be careful to avoid Professor Blyth's arc transmission, and use as hard a carbon and as low an electromotive force as possible.—Yours, &c., E. BERLINER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: If Mr. Smillie will be good enough to read my letter on p. 230 a little more carefully, he will see that I simply intend to point out that there must be a variation of pressure between the electrodes when the transmitter is in action, and that this variation is sufficient to account for all the results. On p. 109 Mr. Smillie sets forth the theory that the action is due to the variable resistance of carbon *per se*. Now, it has been shown over and over again that this is not so, and that the variation of current arises from a variation of conductivity between the electrodes consequent upon the variation of the closeness or the pressure of contact. In not a single one of his experiments has Mr. Smillie attempted, so far as I can ascertain, to eliminate this effect. To prove his case, he should show the behaviour of a block of carbon coppered on opposite sides, and having the circuit wires soldered to the copper, and then, as he objects to vices and steam hammers, he might tickle it with the bristle, or blow upon it with the bellows.

Since he, with considerable fairness, reproduces my reasoning, and agrees with the conclusions I obviously indicated, I fail to see how I am hoist with my own petard. I merely take one objection, and that is to the use of the words "maintenance of a closed contact;" for "contact," I would substitute "circuit." Mr. Smillie set forth with the theory already alluded to, and all I desired to do was to show that in the experiments conducted by him the essential condition of an absolutely closed circuit with no possibility of a variation of resistance save within the carbon itself, which is required to prove his case, was conspicuously ignored.

Will he kindly explain how or when he tried to induce me to sign my name that he expresses sorrow for his failure in obtaining. If the revelation will tend to his happiness, or add force to the argument on either side, it is heartily at his command. I merely consult my personal feelings in employing my initials only.—Yours, &c., W. E. H.

NEW TELEPHONE SWITCH BELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 10th I notice a sketch and description of a new switch bell, the chief feature of which appears to me to be the arrangements of the circuits through the switch, *i.e.*, instead of the movement of the telephone hook working as a switch, to put in circuit the bell or telephone as required, it works as a shunt to short-circuit that portion of the apparatus not required, excepting the double contact springs. There seems to be no other novelty in the bell than that one of the transmitter screws is dispensed with. The bell is stated to have been designed by Mr. Volk for Mr. Haworth. If this is so it is very singular indeed, for I have now in my possession a bell made some ten months ago from drawings and sketches supplied to me by Mr. Haworth, and this bell is, in every particular, similar to the one illustrated in your valuable paper. There is no doubt whatever that the credit of designing the bell belongs entirely to Mr. Haworth. Your readers will, probably, notice that one of the stops for the telephone hook is put in the wrong place.—Yours, &c., W. BANKS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you please allow me to draw your attention to the following improvements in the bell (illustrated and described on page 299, Feb. 10), due to Mr. Haworth, and not myself:—1. The use of screw terminals instead of milled heads, and placing the same at the bottom of the bell instead of at the top. 2. Abolishing one of the connections between transmitter and bell. 3. The arrangement of the circuits so that the telephone and bell circuits are cut out by means of a shunt instead of the usual make and break. 4. The special method of reversing the current by means of the springs s, s', s''.

The stop under the hook lever should have been shown lower. As now shown there would be no room for the lever to travel.—Yours, &c., M. VOLK.

THE ELECTRICIAN.

TO CORRESPONDENTS.

All letters intended for insertion in THE ELECTRICIAN, *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

All communications to be addressed to 396, *Strand, London, W.C.*

We cannot undertake to return drawings or manuscripts, and must, therefore, request Correspondents to keep copies.

SUBSCRIPTIONS.

THE ELECTRICIAN *can be had, by order, from any newsagent in town or country, at the various railway stations; or it can, if preferred, be supplied direct from the office, on the following terms (paid in advance):—*

Quarterly	4s. 10d.
Half-yearly	9s. 9d.
Yearly	19s. 6d.

P.O. Orders to be made payable to James Gray, at West Strand Post Office.

NOTICE.

VOL. IX. of THE ELECTRICIAN,

STRONGLY BOUND, WITH COPIOUS INDEX,

NOW READY.

Price 10s. 6d.

CASES FOR BINDING ALSO READY. Price 2s.

Order of any Bookseller or Stationer.

ANSWERS TO CORRESPONDENTS.

J. D. H. Roubaix.—Vol. IX. dates from May 13 to November 11, 1882. We published a supplement, containing "Hints for Electric Light Engineers," with our issue of January 7, 1882, in pocket form. The publisher has some on hand still; the price is one penny. We intend to publish other supplements from time to time in continuation of the above.

P. N., Haverstock Hill.—The pocket book is not yet completed. We intend publishing additional supplements in continuation of No. 1.

P. Howell.—The works you mention are not printed in English. The most important results contained in M. Deprez's papers have been given from time to time in our columns.

J. M., Jersey.—It would be made an action for libel if we were to answer your question fully.. Our advice would be, have nothing to do with concessions in any shape or form.

THE TELEPHONE APPEAL CASE.

The contest between the several claimants for patent rights in telephones has been renewed so frequently, both in this country and in America, that hardly anything new remains now to be said about it. Its reappearance for nearly a fortnight in the English Court of Appeal during the concluding days of last month and the opening days of the present was noteworthy only in the circumstance that the issues had been narrowed since it came before the Court below, and the claims more strictly defined. For one thing Mr. Edison had eliminated the phonograph from his original specification, the English law permitting that course to be taken where an inventor has inadvertently gone beyond the range of what he finally determines to claim. The Edison carbon transmitter was thus left face to face with the Hunnings carbon transmitter; and the Court below having had no hesitation in deciding not merely that Mr. Edison's invention had priority but that Mr. Hunnings's was an infringement of it, the decision remained unchallenged. In the opinion of many people the invention and publication of the microphone by Professor Hughes ought to invalidate the claims of both these parties—at all events in England; but we can quite understand why neither of them set up a plea which, if it destroyed the pretensions of his rival, would be equally destructive to his own. When the two Foxes quarrelled over the Goose they studiously avoided all mention of the Farmer.

We cannot dismiss this part of the case, however, without once more adverting to the anomalous position in which the decision, just and equitable though it be, has landed us. Mr. Hunnings's transmitter is acknowledged to be a very good one; its predecessor is said to be not so good, and in several respects not so serviceable for everyday use. Be this as it may, one thing appears to be certain, that whatever its superiority might have been, the later invention would have been condemned, and the public consequently deprived of its use, because somebody else had contrived an earlier and similar, though less useful, instrument. This is a case, it seems to us, where patent laws, while very properly protecting the rights of inventors, tend to discourage the efforts of improvers, and are thus not conducive to the public interests. It is nowhere suggested that the Hunnings transmitter is a wilful piracy, or even a colourable imitation; on the contrary, some eminent experts have testified to its being a new and independent invention, besides being one of considerable practical utility. By this judgment it is, we suppose, now shut out of the market, and the public consequently compelled to use another invention, whether they like it or not. Probably the public, if they had any voice in the matter, would disclaim any wish to deprive the first inventor of his rights; but, in public estimation, rights are simply another word for merits, and on their merits respectively the two inventions—so the public would say—ought to stand.

Having said this much on behalf of the improver, and in the interests of the public, we feel ourselves at liberty to be equally candid in respect to original inventors. As regards the main invention involved in this appeal, that is to say the telephone invented by Mr. Bell, we hold that if he had been deprived of his claim on the strength of the plea set up against it the result would have been most deplorable—deplorable not merely in its immediate consequences to the inventor, but to all inventors ever afterwards. It would have shown that no invention, however valuable or however original, is safe from assault on any technical plea that happens to come handy. The one selected in

Digitized by Google

the present trial was that Professor Bell had published his invention before he patented it; and the law of this country is such that only by a quite providential accident did the famous inventor escape the consequences of his indiscretion. The telephone he sent to Sir W. Thomson fortunately would not speak, and, either by accident or design, arrived in a condition so that nobody could make it speak. True, the experts on the other side are now able to persuade it to behave something like the perfect instrument, but this only *after* they have learnt what the perfect thing should be from the very patent which they seek to upset. A flute is no use, as one of the judges remarked, unless you know how it should be played, nor, we may add, if the holes are stopped up, or both ends knocked out.

As to the other pleas urged against Bell's patent, if they are guiltless of mere legal technicality they are hardly less free from the charge of disingenuousness. It is true that Reis and Borseul, and Page, and Varley, and Gray had all been at work in the same field of discovery as Graham Bell, and most of them before his time. If he had independently discovered something which they had already found out it would be much to his credit, but not in the least to his profit. But the fact is he made not only an independent but a totally new discovery. It is by no means certain that the other investigators were even aiming at the result he aimed at—telegraphic signalling being far away different from vocal signalling, and, on the other hand, it is perfectly certain none of them had realised the one condition upon which alone vocal signalling could be accomplished. Here again the instruments contrived by Bell's competitors, notably that of Reis, in the hands of experts, can now be made to speak like a telephone, or, at all events, some people are obliging enough to fancy that it can; but in the hands of Reis it could not articulate, and on the principle of construction adopted by him it never would have articulated, except by accident. That accident did not occur, or, if it did, it threw no light on the cause of its occurrence, and the true conditions of success in vocal telephony remained as dark as ever. To Professor Bell belongs the high, and, indeed, rare merit of starting on fresh lines, pursuing his object on scientific principles, and finally grasping the very thing he was in search of. Having done all this, and having, moreover, done it before anybody else had so much as dreamt of its being done in *that* way, it would be a flagrant injustice to deprive him of any of the fruits of his labour on the plea that *sounds* had already been transmitted by electricity, still less on that of his having sent a crude pattern of his invention in a friendly way to this country before taking legal means of securing it from piracy there.

Electric Lighting in the Mersey Tunnel.—Some time since these extensive works were lit up with incandescent lamps. These have now been supplemented by twenty-four Brush arc lights driven by two Brush dynamos. Twelve of their arc lamps are now being used in the tunnel at the Birkenhead side of the river with good effect, and have proved of great benefit to the men working in the tunnel. The installation at the Liverpool side is now nearly complete. The lights will be brought into use next week. The whole work has been placed in the hands of the Hammond Electric Light and Power Supply Company, Liverpool, and has been efficiently carried out under the superintendence of Mr. J. Shaw, district manager.

Electric Lighting in Italy.—It is said that the town of Alcamo has concluded a contract with a company called the Société Industrielle Franco-Italienne for the lighting of its streets by incandescent lamps.

The Edison Light at the Holborn Restaurant.

On Thursday evening, Feb. 15, we had the pleasure of being present at what might be termed the inaugural dinner of the Edison Installation at the Holborn Restaurant. Mr. Arnold White, the secretary of the company, presided, having as his *vis-à-vis* Dr. Fleming. The guests were, as far as we could gather, principally those employed upon the special installation. During the evening Mr. White referred to his recent visit to Mr. Edison, and to the improvements in the electric light apparatus that indefatigable worker had made during the last three or four months—improvements which it was hoped would place them well to the fore, in spite of any and every competitor. Dr. Fleming referred to the valuable assistance and suggestions received from Dr. Hopkinson, whose ability and energy were so highly appreciated by all who came into contact with him, and especially those present, who knew how much was due to him for those suggestions which, being well carried out, made their work so successful. We were especially struck, as we always are when brought into contact with representatives of Mr. Edison, with the individual belief in the powers of Mr. Edison, in his ability not only to give them equally good, but better lamps and machines than those of other inventors. We like this spirit; we like to see men with faith in the thinkers whose thoughts and realisations have to be carried into practice by them. We do not say that Mr. Edison is the only inventor whose assistants have such a feeling towards him; we could point to other men and other minds for similar examples, but we recognise the fact that those brought into contact with Edison do throw their hearts into their work, and the result is seen in the many successes which have been achieved with his system. The English Company is to be congratulated upon the success of the installation at the Holborn, and we trust it is but the first of a large number of similar installations that we shall have to record.

The Holborn Restaurant is so well known to those who live in or frequently visit London, being one of the most popular establishments in London, that we need not refer to it at length. During the last year it has been undergoing extensive alterations, which it is hoped will be finished in a few weeks, when some of the finest rooms in the metropolis will be at the command of the public. It has been decided as one of the improvements to substitute the electric light throughout the premises for gas, and this work was placed in the hands of the Edison Company. The necessary plant for 500 sixteen candle lamps has been placed in position at 10, Little Queen-street, a building adjoining the restaurant. The plant consists of two K or 250 light dynamos, driven by two of Ransome's semi-portable engines specially built for electric light work, each of sixteen horse-power nominal, and fitted with automatic governors. From the generating station the current is conveyed underground by the system of leads designed by Mr. Edison, through the churchyard of Trinity Church to the building to be lighted. The whole of the internal fittings are not yet complete, owing to the fact that a portion only of the building is undergoing alteration at one time. When the whole is complete, we hope to be able to give a plan of the circuits, &c. The rooms completed are those known as the Prince's and the Colonel's room. The dinner we have briefly referred to above was held in the Prince's room, which we thought well lighted with 18 A (16 candle) lamps. We do not believe in overlighting any more than we believe in underlighting, though the latter may be tolerated, while the former is dangerous. We closely watched the lamps for several hours, and they gave an admirably steady light of, we should judge, quite 16 candles per lamp. We felt more strongly than ever that the incandescent light is as superior to gas as gas is to a tallow candle, and that it is a mere question of time for the one to be adopted in place of the other. The number of lamps to be sustained by the plant is about 650, partly A and partly B (eight candle) lamps. The remainder of the lamps required for the building will be supplied from the station at 204, High-holborn. The fixtures, which, so far as we could judge, are elegant and tasteful, have been designed and supplied by Messrs. B. Verity and Sons, of King-street, Covent Garden.

STUDENTS' COLUMNS.

CITY AND GUILDS EXAMINATIONS.

[*These answers are intended to guide, to give information and references, to put the student in the way of getting information, and* NOT *to give the exact answers that should be written in an examination.*]

The solutions in this number are solutions to some of the "*Honours*" questions in the paper hitherto considered, by E. C. RIMINGTON, ESQ. (School of Electrical Engineering), 12, Princes-street, Regent-street.

15. Describe methods of ascertaining the exact connection between the speed of the generator, the speed of the motor, the resistances of the machines and of the connecting wires with the efficiency obtained in the electric transmission of power.

Ans. If E be the total E.M.F. of the generator, and E_1 be the total back E.M.F. of the motor, that is to say, the E.M.F. produced by the rotation of the motor, and which always opposes that produced by the generator, and ΣR be the total resistance in circuit, current $= \frac{E - E_1}{\Sigma R}$.

Horse-power applied to drive generator

$$= \text{H.-P.} = \frac{EC}{746} = \frac{E(E - E_1)}{746 \Sigma R}.$$

Horse-power expended electrically by the motor

$$= h.p. = \frac{E_1 C}{746} = \frac{E_1 (E - E_1)}{746 \Sigma R}.$$

Now, efficiency is the ratio of the horse-power put into the generator to the horse-power given out by the motor

$$= \frac{h.p.}{\text{H.-P.}}$$

$$= \frac{\frac{E_1 (E - E_1)}{746 \Sigma R}}{\frac{E (E - E_1)}{746 \Sigma R}} = \frac{E_1}{E}.$$

When current is constant E.M.F. varies as speed. Let S be speed of generator and s be speed of motor. According to Professor Lodge

$$\text{E.M.F.} = \frac{K S \rho \phi C}{2}$$

where K is a constant depending on the size and arrangement of the armature of the machine; S = speed; ρ = internal resistance of generator; and ϕ is a function determined by the size, shape, and quality of iron of the dynamo.

In a dynamo to obtain the maximum efficiency *per se* the resistances of the armature and field-magnets should be equal. If this be not the case the above equation would be written

$$\text{E.M.F.} = K S \sqrt{a b}\, \phi C.$$

Now, efficiency $= \frac{h.p.}{\text{H.-P.}} = \frac{E_1}{E} = \frac{\frac{K_1 s \rho_1 \phi_1 C}{2}}{\frac{K S \rho \phi C}{2}} = \phi_1 \frac{K_1 s \rho_1 \phi_1}{K S \rho \phi}$.

If the two dynanos are exactly similar efficiency $= \frac{s}{S}$.

16. Given the resistance of the generator and motor, and of the line wire per mile, calculate a formula which tells the amount of power lost from the heating of the wires when a certain amount of power is transmitted over a certain number of miles. Apply your formula to several numerical cases.

Ans. The heating of the wires entirely depends on the amount of current passing, and is equal to $C^2 R$.

The amount of current passing depends on the relation between the E.M.F. of the generator and the opposing E.M.F. of the motor. The more nearly the latter approaches the former, the less the current passing, the less the total power in the whole circuit, but the greater the ratio of the power transmitted to the total power. From the resistance of the wire on the machines and that of the line wire, it is, therefore, impossible to calculate the required formula. If, however, some other datum, such as the E.M.F. of the generator, the back E.M.F. of the motor or the current, be given, we can obtain this formula.

Let us first suppose that the current is given, then the power absorbed in heating the wires $= \frac{C^2 R}{746}$ h.-p., where R is the resistance of the generator, the line wire, and the motor.

Next, let us suppose the back E.M.F. of the motor to be given. Call this e.

Let w be the power transmitted expressed in horse-power, ρ = resistance of generator, ρ_1 = that of motor, r = resistance of line wire per mile, and n = number of miles of line wire.

Call the sum of these resistances R, so that

$$R = \rho + nr + \rho_1.$$

Let E = E.M.F. of generator, an unknown quantity at present, and W = power put into the generator, also unknown at present.

Then we have the following two equations:—

$$\left.\begin{aligned} \frac{w}{W} &= \frac{e}{E} \quad (1.) \\ W &= \frac{E(E - e)}{746 R} \quad (2.) \end{aligned}\right\}$$

From (1.)

$$W = \frac{w E}{e}$$

$$\therefore \frac{w}{e} = \frac{E(E - e)}{746 R}$$

$$\frac{w}{e} = \frac{E - e}{746 R}$$

$$E e - e^2 = 746 w R$$

$$E = \frac{746 w R + e^2}{e}$$

$$\therefore W = \frac{\frac{w (746 w R + e^2)}{e}}{e} = \frac{w (746 w R + e^2)}{e^2}$$

But power absorbed in heating the wires is the difference between the power put into the generator and that given out by the motor. $= W - w$.

$$\therefore H = W - w = \frac{w (746 w R + e^2)}{e^2} - w;$$

$$= \frac{w (746 w R + e^2 - e^2)}{e^2} = \frac{746 w^2 R}{e^2};$$

$$= \frac{746 w^2 (\rho + nr + \rho_1)}{e^2}.$$

Again, suppose we know E and do not know e, we have, as before,

$$\frac{w}{e} = \frac{E - e}{746 R},$$

$$e(e - E) = -746 w R,$$

$$e^2 - E e + \left(\frac{E}{2}\right)^2 = \frac{E^2 - 2984 w R}{4},$$

$$e - \frac{E}{2} = \frac{\pm \sqrt{E^2 - 2984 w R}}{2},$$

$$e = \frac{E \pm \sqrt{E^2 - 2984 w R}}{2},$$

$$\therefore W = \frac{2 w E}{E \pm \sqrt{E^2 - 2984 w R}},$$

$$\text{and } W - w = \frac{w (2E - E \mp \sqrt{E^2 - 2984 w R})}{E \pm \sqrt{E^2 - 2984 w R}}$$

$$= w \cdot \frac{E \pm \sqrt{E^2 - 2984 w R}}{E \pm \sqrt{E^2 - 2984 w R}}$$

Multiplying numerator and denominator by

$$E \mp \sqrt{E^2 - 2984 w R}$$

we obtain

$$H = \frac{w (E \mp \sqrt{E^2 - 2984 w R})^2}{E^2 - E^2 + 2984 w R}$$

$$= \frac{(E \mp \sqrt{E^2 - 2984 w R})^2}{2984}$$

$$= \frac{E^2 + 1492 w (\rho + nr + \rho_1) \mp E \sqrt{E^2 - 2984 w (\rho + nr + \rho_1)}}{1492 (\rho + nr + \rho_1)}.$$

In practice the minus sign will be the one employed in the expression

$$\mp \sqrt{E^2 - 2984 w R}.$$

SELF-REGULATING DYNAMO MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of Jan. 6 you speak of "taking some members of the technical press into confidence, and put out of question once and for all claims to priority by a suitably worded paragraph which records but does not enter into details." Your observation may be a very just one, but it is open to several objections. There are, unfortunately, in the world a great many people who claim for their inventions what is not a peculiarity of their invention particularly, yet who will say when they hear that So-and-so does with his invention such-and-such a thing, "Oh, mine does all that." But it does not. So when, after previously indicating the advantages of your invention, you come to bring it before the public, it is really astonishing to find how many old inventions are claimed to have that peculiarity. I will trouble you with an instance. We all know that it is practically impossible to burn an arc lamp and an incandescent lamp together on a simple shunt-circuit machine unless there is very wasteful resistance in the arc lamp circuit; at least, we all ought to know it, because the reason is simple enough, and can be easily seen to be that the very small external resistance during contact of the carbons reduces the potential difference at the ends of the shunt-coil to too low an amount to charge the magnets. Yet I have thrice this week been told that the "combination" system had no advantage in this respect. In the last case I insisted on seeing so extraordinary an improvement on common sense, and had shown to me a merely ordinary series dynamo as "self-regulating." Verily, the world—or some of it—has assurance. I think, however, I will turn purchaser of one of these pseudo-inventions, and having effected my purchase under strict agreement and otherwise unconditionally, I will prosecute my vendor for obtaining money under false pretences.

Another reason is that in some countries such a publication would invalidate one's application for a patent. Your correspondent, Mr. Menges, seems to intimate that this is the case in Germany. *How much better would it be if priority of publication in scientific journals gave prior patent right!* As it does *not*, but unfortunately *invalidates* that right (as has been contested in the telephone case, for example), the choice lies between fame and bread and cheese. Many inventors are like me, they prefer the latter.

Yet another reason is illustrated in the letter of your correspondent Mr. Menges. Appearing at the close of a discussion as to priority it would indicate, without giving any date, a desire to claim priority to my patent of 1881 for the "combination" shunt and main-circuit magnet system of winding dynamos, and to endeavour to base a new invention on the place of connection of the shunt wires. Don't you think that when communications are made *in confidence* they should be backed up by some statement as to date, and that the editor receiving the communication should, as in the present instance, intimate the date? Speaking as having been an editor myself, I would do so affirmatively.

Your correspondent, Mr. Menges, appears to claim the insertion of the shunt-circuit at the machine terminals; perhaps some one will be kind enough to patent their insertion on the nth convolution of the main-circuit magnet. The only sensible suggestion I have seen is that described by Professor Sylvanus Thompson in his Cantor lecture, and termed the "Long-Shunt" combination system, one that I use under some arrangements of external circuit, and used in the autumn of 1880.

I think I have given you three fair reasons for secretiveness in inventing, and I fear that these reasons will hold good until you can induce the authorities to alter their dictum that priority shall depend on date of patent and not of publication in a journal of known issue. But why not agitate for this alteration, one that would give every workman far greater protection than "provisional specifications" of any kind?—Yours, &c., PAGET HIGGS.

ERRATUM.—On page 329 of our last issue we attributed our abstract of the report of an interview with Mr. Edison to the *New York Sunday Herald*. It should have been the *Boston Sunday Herald*. Last week's abstract dealt with Mr. Edison's opinion on storage batteries. In next week's issue we shall give his opinion on electric lighting.

CANTOR LECTURES.*

DYNAMO-ELECTRIC MACHINERY.

BY PROFESSOR SILVANUS P. THOMPSON, B.A., D.SC., M.S.T.E.

Lecture III. (concluded).—The Dynamo as a Motor.

(CONCLUDED FROM PAGE 329.)

It is, of course, possible to use as a motor any direct current dynamo, whether the field-magnets be series-wound, shunt-wound, separately excited, or permanently magnetised. There is this curious point of difference in different cases. Suppose the dynamo to be arranged so as to work as a generator, and then to be supplied with currents from an exterior source, to make it work as a motor. If the dynamo is series-wound, it will run the reverse way (or against its brushes), no matter which way the currents run through it. If the dynamo be shunt-wound, it will run with its brushes, whichever direction the current runs through it. The direction of rotation taken by the separately-excited and the magneto machine will also be with the brushes, if the current is in the right direction, through the armature. These points have to be taken into account in any attempt to combine the different systems.

If we attempt to apply to motors rules and suggestions, such as these applied to generators in the first of these lectures, we shall find that, whilst some of them apply directly, others are singularly in contrast. For example, we found it advisable, for the sake of steadying the currents in generators, to use large and long field-magnets with plenty of iron, and with heavy pole pieces. In the case of motors, there is no such necessity laid upon us; for we want here to produce a uniform steady rotation. Now, even if the impulses be intermittent, the mechanical inertia of the moving parts will steady the motion. Electric currents have no such inertia (except in so far as the self-induction in a circuit exerts an influence like that of inertia), and hence the precautions for generators. In the case of generators, we found that, to produce steady currents, we had to multiply coils on the armature in many separate paths, grouped round a ring or a drum, involving a complicated winding and a collecting apparatus, consisting of many segments. In motors no such necessity exists, provided only we arrange the coils that there shall be no dead points. I do not say that, for large motors, it may not be advisable to multiply the paths and segments for other reasons—as, for example, to obviate sparking at the collectors—but, for securing steady running, the inertia of the moving parts spares us—at any rate, in small machines—the complication of parts which was expedient in the generator. Some of the most successful of the little motors that have recently appeared—those, for example, of Deprez, Trouvé, and Griscom—have for their armatures the simple old shuttle-wound Siemens armature of 1856, and in these motors, of course, there is the disadvantage of dead-points to take into account. Deprez, in his first motors, placed this armature longitudinally between the poles of a horse-shoe magnet, with the axis parallel to the limbs. He has also constructed motors with two such armatures on one spindle, one of the coils being 90deg. in advance of the other, so that while one was at the dead point, the other should be in full action. The same suggestion has been carried out in Akester's motor. Trouvé has tried to get over the dead-points, by utilising the method of oblique approach mentioned earlier in my lecture. The Griscom motor, which has little copper rollers as commutator brushes, has, for field-magnets, a compact tubular electro-magnet wound in series with the armature. It has the disadvantage of dead-points. There is, in all these motors, the disadvantage that at every half-revolution the magnetism of the armature core is reversed; and as in all these forms this core is of solid iron, there must be waste by heating in the cores. In fact, to the rotating armatures of motors, as to those of generators, apply all the rules about slitting to get rid of induced eddy-currents, avoiding idle coils and useless resistances, &c. The rules about proper pole-pieces, adjustable brushes, multiplication of contacts, also are mostly applicable to motors as well as to generators.

In order to meet the case of a handy and reliable motor, I have designed a machine, the smallest size of which is on the table before you. The field-magnets, which also constitute the bed-plate of the motor, are of malleable cast iron, of a form that can be cast in one, or at most two, pieces. The form of them is that of a Joule's magnet, with large pole-pieces, and wound with coils, arranged partly in series, partly as a shunt, in certain proportions, so as to give me a constant velocity when worked with an external electromotive force of a certain number of volts.

As an armature, I employ a form which, I think, unites simplicity with efficiency for the end desired. I do not want dead

* Reprinted from the *Journal of the Society of Arts*.

Digitized by Google

points, and yet I do not want to have a complicated armature. I have, therefore, modified the old Siemens armature by embedding, as it were, one of these shuttle-shaped coils within another, at right angles to one another. And having duplicated the coils, I must, of course, duplicate the segments of the commutator, which, therefore, becomes either a four-part collector, or else a double collar, according to circumstances. There are no solid iron parts in the armature, but the cores are made of thin pieces of sheet iron, stamped out and strung together. Of the efficiency of this little motor you were witnesses a little while ago, when I employed it in the experiment with the galvanometer.

There are here on the table two other forms of moter, one of which is the design of Mr. A. Reckenzaun, C.E., and which is interesting because its armature, though a drum-armature in form, in reality consists of independent coils, connected, like those of the Brush dynamo, to separate commutators. There are, in fact, four commutators grouped as two twos, and two pairs of brushes in contact with them.

The other motor is one of the pattern invented by De Meritens, who employs a ring-armature very like that of Gramme, but places it between very compact and light field-magnets, which form a framework to the machine. There is one point about this machine of great interest, which is, however, a later addition. It is provided with a reversing gear, which, when I move the handle, reverses the direction in which it runs. This gear, which is the invention of Mr. Reckenzaun (to whom I am indebted for the loan of this motor) is shown in Fig. 38. In it there are two pairs of brushes; the two upper are fixed to a common brush-

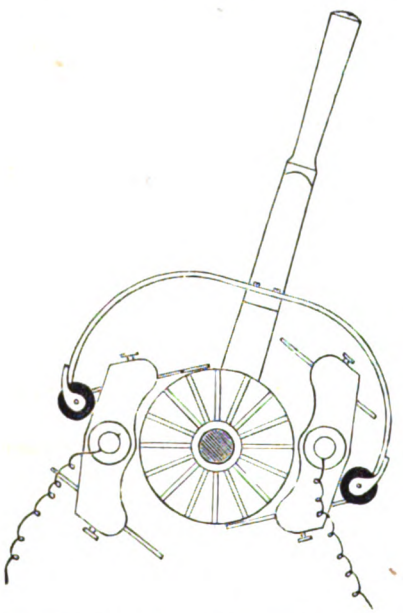

FIG. 38.—Reckenzaun's Reversing Gear.

holder, which turns on a pivot, and can be tilted by pressing a lever handle to right or to left. The two lower brushes are also fixed to a holder. Against each brush-holder presses a little ebonite roller, at the end of a bent steel spring, fixed at its middle to the handle. The result of this arrangement is that, by moving the lever, the brushes can be made to give a lead in either direction, and so starting the motor rotating in either direction. Such a reversing gear is obviously a most essential adjunct for industrial applications of motors, and, if the difficulties of sparking at the brushes, caused by the sudden removals of them from the collector, be obviated, must prove much better than any mechanical device to reverse the motion, by transferring it from the axle of the motor through a train of gearing to some other axle. One great advantage of electric motors is, that they can be so easily fixed directly on the spindle of the machine they are to drive; an advantage not lightly to be thrown away.

There is, indeed, an immense field for useful industrial application of electric motors, so soon as we once have at our disposal regular town supplies of electric currents. Already we have got the little motors of Griscom, Howe, and others, adapted to work sewing machines and instruments requiring very small power. Larger motors, for driving lathes and heavier machinery, though not yet much known to the public, are in the market. Messrs. Siemens have brought out an electric lift or elevator,* in which a small dynamo, itself running very quickly, drives an endless screw, and communicates a slow, but powerful, motion to a drum, on which the hauling chain is wound. If town-supplies of electricity were accomplished facts, such lifts will be multiplied. Indeed, there are very many purposes for which hydraulic power is used, for which electric power might be advantageously substituted. The electric railway, dimly foreshadowed by George Little, in 1844, when he patented an "electro-locomotive," has become an established fact. From the electric railway first established in Berlin, in 1880, by Siemens and Halske, we already have had the further developments of the electric tramway in Paris, and the experimental electric railway at the Crystal Palace. Edison has constructed an electric railway at Menlo Park, and built electric locomotives to ply upon it. Nor must I omit to mention how, in the bleaching fields of France, an electric tramway does most satisfactory duty; nor how, finally, in the sister isle, at the Giant's Causeway, Messrs. Siemens Brothers have established a line of electric railway, which is now actually in operation.

Latest of all the applications of the dynamo as a motor is that of electric navigation. Jacobi, as we know, fitted up, in 1838, an electric paddle boat, which he propelled on the Neva, first with Daniell's and afterwards with Grove's cells, and was even able, when he used 128 large cells, to carry fourteen persons against the stream, at a speed of about 1¼ miles per hour.

M. Trouvé, of Paris, was the next to apply electric power, in the shape of Planté's accumulators, to a pleasure boat, with which he navigated the Seine. But M. Trouvé has more recently abandoned storage cells, and has returned to the use of a bichromate battery, wherewith to drive the little boats, which he fits up with his little motors, mounted upon the top of the rudder, and turning a light screw-propeller by a driving belt, which passes down behind the rudder into the water.

Still more recent is the electric launch which made its trial trip on the Thames* last September. This is an iron boat twenty-five feet long, fitted with a screw, and able to carry twelve persons while running against the tide, at a pace of eight miles an hour. No existing motor of requisite power having yet been made of a form convenient to place directly upon the axis of the propeller, the expedient has, in this case, been resorted to of driving the screw by belts from an overhead counter-shaft, which receives its motion from two small Siemens dynamos placed below. Each of these dynamos has been provided by Mr. Reckenzaun, who designed the fittings of the launch with reversing gear like that shown in Fig. 38. The current which actuates these dynamos is derived from forty-five accumulators of the Sellon-Volckmar type, which are charged while the launch lies at its moorings. Though this is a great step in electric navigation, I venture to believe that it is yet but a beginning of greater things. As with steamboats, so with electric boats, we shall find that we begin with small experimental attempts, and increase in size as experience dictates. It is but a few days since I was reading in an old volume of the *Philosopoical Magazine* for the year 1801 of Symington's early little steamboat—the forerunner both of Fulton's and of Bell's—and the writer of the article hardly dared to think of this as more than an ingenious experiment, and doubted whether large vessels could ever be practically driven by steam. When I read this curious narrative, I bethought me of the trial trip of the little launch "Electricity," and began to think that I was not so very hopelessly wrong, when I wrote in September last, "Who shall say to what proportions this latest application may not attain in the next decade?"† Could we look forward, and see with our eyes to-night the electric boats of fifty years hence, we should not, perhaps, be more surprised than those who beheld the first rude steamboat would be, if they could now rise from their graves to behold the great ocean-going steamships of to-day. Indeed, when I look around and see so many opportunities for the future application of electric motive power, so many instances in which the dynamo would supply a welcome and economical‡

* Dr. Hopkinson has also invented an electric lift, in which the armature of the motor, running at a high speed, works the chain of the lift by a train of toothed wheels, which reduce the speed. This elevator was shown in operation at the Paris Exposition of 1881.

* In 1856, Mr. G. E. Dering constructed, at Messrs. Searle's, an electric boat worked by a motor, in which the rotation was effected by magnets arranged within coils, like galvanometer needles, and acted on successively by currents from a battery. It succeeded, I am informed, in making headway, though at small speed, against the tide at its swiftest.

† It is well known that a no less authority than Dr. Lardner publicly pronounced it impossible for any steamboat ever to carry coals enough to enable her to cross the Atlantic. It is also recorded that a very eminent public man offered to swallow the boilers of the first steamboat that should succeed in crossing the Atlantic. But he would be a bold man who would nowadays promise to swallow the accumulators or the dynamos of the first electric boat that shall successfully make the same trip across the water.

‡ As to the economy of electric motive power, I may, perhaps, be allowed to quote a passage from a recent lecture of my own in Bristol, in which a concrete case is presented:—"When it is possible thus to obtain power by merely turning on a tap, there will be an enormous impetus to all kinds of small machinery. Motors to work sewing-machines already

Digitized by Google

means of doing that which is now done by less advantageous means, I begin to wonder why we do not establish central supplies of electric currents for this purpose, which is surely as important as electric lighting. Here we have the possibility of introducing machinery that is portable and light, giving us power without the inconveniences and risks hitherto attending the employment of power. Surely there must be many workshops in every town where the owner would be glad of having power without the trouble and danger of a furnace, boiler, and steam-engine, or even of a gas-engine, in his place; where a boiler cannot be put for want of space, and where a steam-pipe cannot be carried because of the inevitable condensation. So thoroughly am I convinced of the great future that lies before dynamo-electric machinery, from this point of view, that I am disposed to think electric lighting a very small item by comparison.* When once we get a proper system arranged for the general distribution of electric currents in a regular town supply, we shall begin to realise the hundreds of ways as yet undreamed of in which electricity may be utilised to meet our wants, and to subserve the ends of civilisation.

ON ELECTRIC LIGHTING FOR WORKSHOPS AND LARGE SPACES.†

By Mr. ANDREW JAMIESON, A.M. Inst. C.E., F.R.S.E., &c., Principal, College of Science and Arts, Glasgow.

The subject of electric lighting has lately received a large amount of attention from many of our most scientific and practical men, public interest has been greatly awakened regarding it, and the Patent Office has been inundated with specifications and applications all more or less proposing to give us perfect electric lighting. Numerous companies have been formed, with large subscribed and still larger nominal capital, with a view in some instances only to sell patents and patent-rights; in others, with the more honourable and honest purpose of making and installing their appliances, each one claiming its speciality or system to be the best either as a whole or in some particular feature.

Our leading scientific and engineering journals have of late been full of descriptions of this or that dynamo and electric lamp, or of some special installation or electrical exhibition, using terms and electrical phraseology which to some must have appeared new and difficult to understand.

There is at the present moment scarcely a town in the kingdom which has not had a trial of the electric light, and whose authorities are not worrying themselves as to whether they shall or shall not seek for a "provisional order," and thus have the right, under the Board of Trade, of supplying their inhabitants with "the light of the future."

In this paper I do not propose to describe anything very new or startling; neither do I wish to advocate one particular system in preference to another (for I have no pecuniary interest in any of them), but rather to lay before you a short description of how the various and necessary appliances are constructed and applied in order to produce electric lighting suitable for workshops and large spaces, and to make clear a few of the most common of the electrical terms, as well as to compare the efficiency and cost of electric lighting with that of gas lighting.

Practical Electrical Units of Measurement.

In the first place I shall define the several units of measurement required in measuring electrical currents in connection with electric lighting. The practical electrical units of measurement, now universally adopted by all electricians, were finally determined upon at the International Congress of Electricians, Paris, 1881, and British Association, 1882.

Since electricity, by whatever means generated, is the result of the expenditure of energy (mechanical energy, as a rule, in the case of electric lighting), and as the measurement of energy involves *space*, *matter*, and *time*, the three fundamental units adopted were the centimetre for length, gramme for mass, and second for time, which is termed the centimetre, gramme, second system, or, shortly, the C.-G.-S. system; and upon these fundamental units all the practical electrical units of measurement are based.

Analogy Between Water and Electricity.

An electric current may, for all practical purposes, be considered analogous to a fluid, under conditions somewhat similar to those by which water flows along a pipe.

1.—*Electromotive Force Compared to Head or Pressure.*—The difference of level or pressure, due to gravity, between the top and bottom of the water pipe (Fig. 1)*; in other words, the "*head*" causes the flow of water

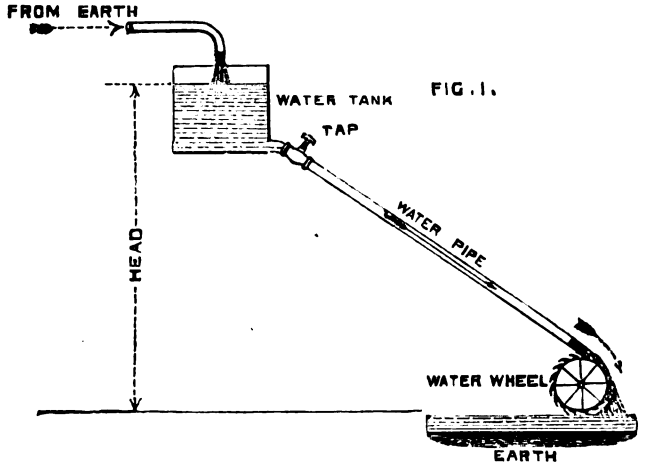

FIG. 1.

along the pipe, while the difference of potential or electrical pressure between the ends of copper wire (Fig. 2),* in other words, the *electromotive force*, as it is termed, causes the flow of electricity along the wire. The potential or pressure, in both cases, determines the power of doing work, as illustrated by the water now flowing from the elevated tank along the pipe and driving the small water-wheel on the table, and by the voltaic

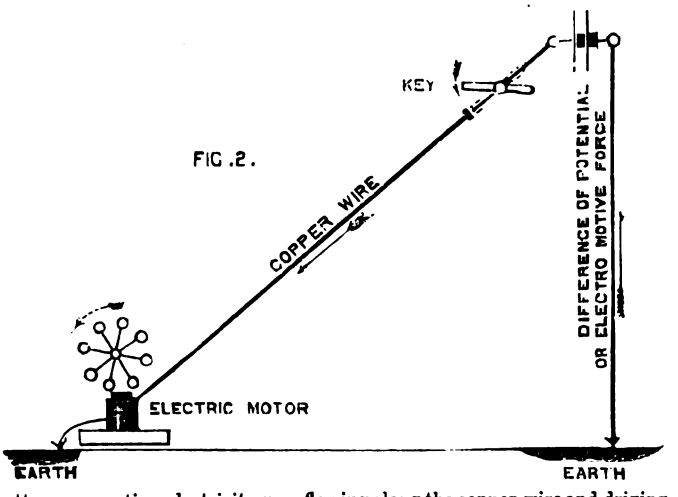

FIG. 2.

battery generating electricity now flowing along the copper wire and driving the small dynamo-electric engine, also on the table, and usefully employed pumping water.

2.—*Electric Resistance Compared to Friction.*—The *friction* generated between the running water and the inside of the pipe offers a certain amount of resistance to the flow of the water, and may be considered so far analogous to the *resistance* offered by the metallic conductor to the flow of the electricity along it.

---

exist, and would be used literally by millions, if the source of electricity were but at hand, in the form of a friendly wire always ready to bring the needed power. . . . . Again, the establishment of a town supply of electricity will tend unquestionably to develop the industries of small workshops and home workshops, where a little power is required. I have already explained how, with steam power, small engines of one horse-power or less are uneconomical. But with electricity it is not so. The smallest electro-motors may be made just as economical as are the largest There is, moreover, another point in their favour. They may be made far smaller, lighter, more compact, and far cheaper than steam-engines of corresponding power. . . . . It is certainly possible to construct an electric-motor of two horse-power for ten pounds, and such a motor would be ample for the purposes of many small workshops. Why do we not, it may be asked, hear and see more of these little machines, if they are so excellent? Why do not people adopt them? The answer is simply they cannot be used until we have a central supply of electricity. I do not hesitate to affirm that such motors will be found to present an enormous economy in comparison with steam-engines of equal power. Take the case of a small workshop, which wants just two horse-power to turn a few lathes or drilling machines. A small steam-engine and boiler will, together, cost about £70, and the consumption of coal will be about 13lb. weight per hour. Instead of this, put in a motor costing, let us say, £20, which allows for handsome profits on manufacture. Here is a saving in capital outlay at once. Moreover, the motor may be put right into the workshop, for it is small—perhaps, 2ft. long, 18in. broad, and 1ft. high—and is not liable to leak or explode. The next point to consider is the cost of running it. Let us suppose that it has only an efficiency of 70 per cent., or that it only turns 7-10ths of the energy of the current into useful mechanical work. (Many motors will do far more than this.) Let us also suppose that the currents are furnished by a dynamo, whose efficiency is 90 per cent. (which figure is also capable of being attained in practice), worked by a large central steam-engine, consuming only 1½lb. of coal per horse-power. Allow 4 per cent. for loss, by resistence, in the conducting cables; this reduces the total efficiency of the generator to 86 per cent., and of that 86 per cent. only 7-10ths—*i.e*, 60·2 per cent.—is generally converted back into useful work by the motor. We have, then, 40 per cent. wanted in order to get 60 per cent. of useful work. How does this affect the coal consumption for two horse-power? At the central station 3lb. of coal per hour would suffice were there no loss in conversion into electric energy, and back again into mechanical power. As it is, 5lb. of coal per horse-power will be needed, 3lb. of which represent the 60 per cent. of useful power transmitted, and 2lb. to represent the 40 per cent. wasted. In practice, I believe, a far less margin of waste might be looked for. Yet even with this large waste there is still an immense economy effected, for we get our two horse-power by an expenditure of 5lb. of coal at the central station, instead of 13lb. of coal in the furnace of a small steam-engine. It is clear, then, that electricity offers an enormous future to small motor machinery."

* What is the proportion of coal used for the manufacture of gas in Great Britain, compared with the amount consumed in procuring motive power. The answer to this query amply justifies my view.

† A Paper read before the Institution of Engineers and Shipbuilders in Scotland.

* These models were kindly lent to the lecturer by Mr. White, Optician, and Messrs. Baird and Tatlock.

Digitized by Google

3.—*Strength of Electric Current Compared to Flow of Water.*—The flow of the water along the water pipe, and the strength of the electric current along the conducting wire, are in each case determined by the pressure overcoming the resistance.

4.—*The Quantity of Electricity Compared to the Volume of Discharge or Volume of Flow of the Water* is in each case determined by the current passed in a second.

5.—*Power.*—In order to estimate the power of the current developed in each case, we have simply to multiply the total pressure by the current passed per second.

Exact Definitions of Practical Electrical Units.

1.—*Electromotive Force* = (E).—*The Volt* is equal to 10^8 C.-G.-S.* units of electromotive force, or about 8 per cent. less than the E.M.F. of a standard Daniell cell. Electromotive force is equivalent to the difference of potential between two points.

2.—*Resistance* = (R).—*The Ohm* is equal to 10^9 C.-G.-S.* units of resistance. It is equal to the resistance of a column of pure mercury 1·0624 metres long, of a square millimetre section, at the temperature of zero centigrade; or roughly, the resistance offered by 240ft. of pure copper wire, No. 18, B.W.G. (1-20th inch, or 1·274 millimetres in diameter), at 60° Fahr., is equal to one ohm. Resistance of copper increases with the temperature by about 0·21 per cent. per degree Fahr. Resistance varies directly as the length, and inversely as the sectional area of the conductor.

3.—*Current* = (C).—*The Ampere* is equal to 10^{-1} C.-G.-S.* units of current. It is the current produced by a volt through an ohm.

$$\text{Ohm's law...current} = \frac{\text{electromotive force}}{\text{resistance}}, \text{ or } C = \frac{E}{R}.$$

4.—*Quantity* = (Q).—*The Coulomb* is equal to 10^{-1} C.-G.-S.* units of quantity. It is the quantity of electricity given by an ampere in a second.

5.—*Power* = (P).—*The Watt* is equal to 10^7 C.-G.-S.* units of power. It is the power conveyed by a current of an ampere through a conductor whose ends differ in potential by a volt; or, in other words, the rate of doing work when an ampere passes through an ohm, and it is equal to 10^7 ergs (1·746th of a horse-power).

$$\therefore E \times C = \text{Watts, and } \frac{E \times C}{746} = \text{horse-power} = 33{,}000\text{lbs. per min.}$$

Motive Power for Driving Dynamos.

Before describing the dynamo, or generator of electricity, I shall just say a word or two about the most suitable machines for producing the mechanical power which has to be converted into electrical energy by the former.

First, we have the steam engine; second, the gas engine; third, the water-wheel or turbine; fourth, the wind mill; and a fifth has been proposed, but not yet put into practice, viz., a machine for utilising the rise and fall of the tides.

Of all these, the most suitable and, at the present time, the most popular, is the steam engine. Whatever kind of machine is adopted, it is absolutely necessary that so long as the power developed by it is applied to driving a dynamo, in direct circuit with the electric lamps, the motion should be as uniform as possible, in order to insure a steady current or electromotive force. For this purpose, in the case of the steam engine, it should be fitted with a sensitive and efficient governor, and it should be capable of easily furnishing the necessary power without in any way overstraining any of its parts, and be constructed of the very best materials and in the best possible manner, so as to minimise the chance of a breakdown. In the case of workshops, where there is an ample reserve of power developed by the shop engine, and the demand upon its energy does not alter very rapidly, it has been found suitable, in many instances, to drive the dynamo by means of the same; but this should not be attempted before carefully testing and considering well the capabilities of the engine.

The demand for electric lighting has necessitated a special class of engines for this work, and several well-known makers, notably Messrs. Marshall and Sons and Messrs. Tangye Brothers, have devoted much attention to this subject. The driving connection between the engine and the dynamo is usually carried out by means of belting either direct from the fly-wheel to the dynamo pulley, or by the intervention of a counter shaft.

It is only in the case of steamships, or where the space is limited, that the motion is communicated direct from the engine shaft to the dynamo, without the intervention of belting or gearing, and in such cases the engine must be run at a very high speed, or the dynamo so arranged as to work at an abnormally slow rate.†

Gas engines are becoming more popular, and, by using a fly wheel on the dynamo shaft, with long slack belting to counteract the effect of their somewhat irregular motion, they are, in many instances, found very serviceable. Sir William Thomson has adopted a six horse-power Clerk's gas engine at his laboratory, and Professor Blyth, at Anderson's College, an eight horse-power one, apparently with good effect.

Water power has, as yet, been but sparingly employed, either through the intervention of water-wheels or turbines, probably from the fact that where the electric light is in greatest demand, water is not available; but there cannot be much doubt that, as the mill-owners whose works are supplied with plenty of water power begin to realise the advantages of this form of artificial light, water power will be greatly taken advantage of; and, from the ease with which it can be manipulated, it will be found quite as efficient as the best steam engine, and certainly prove less costly.

Windmills and tidal machines are out of the question until that much-required desideratum, viz., the storage of electricity, can be economically effected.

* Electro-magnetic system. For the other units see Rankine's "Rules and Tables," sixth edition.

† As examples, we have the electric lighting on board the ss. "Servia" by means of Swan's lamps, where a Brotherhood's three-cylinder engine, running at about 600 revolutions per minute, drives direct Siemens's exciter and alternate current dynamos; and the ss. "Waihora," just completed this week by Messrs. Denny, of Dumbarton, and fitted throughout upon Edison's system with 150 incandescent lamps, the dynamo being driven direct by a three-cylinder Brotherhood's engine running at 500 revolutions per minute.

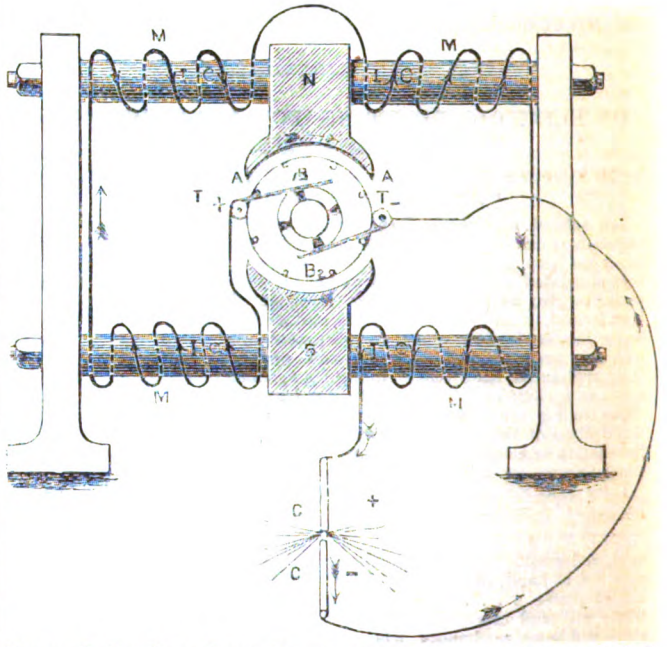
Dynamos.

We now come to the dynamo, or producer of electricity, for feeding electric lamps.

Gramme Dynamo.—To illustrate the general principle upon which this machine depends, your attention is called to Fig. 3, where

S represents	Shaft
A, A,	armature revolving between
N, S,	the north and south seeking poles of
M, M, M, M,	the electro-magnets, around the
I, C, I, C,	iron cores of which the wire from
T +	the + terminal of armature is wound as shown until it joins the
C +	carbon (+) or upper carbon of the arc lamp,
T −	the (−) terminal of armature being joined to
C −	the carbon (−), or lower carbon, of the arc lamp;
B_1, B_2	the brushes which collect the current from
C	the commutator, whose metallic parts are soldered to the nearest points of the coil of wire which forms the armature.

FIG. 3



Note.—In the above figure the armature is shown at right angles to its true position for clearness.

There being always some residual magnetism in the pole pieces N S and iron cores I C (after having once been magnetised), there exists a weak magnetic field between N and S, and the lines of force pass through the armature A A and its iron core, at right angles to the copper wire coiled round the same. Consequently, upon revolving the armature A A, its copper wire coil cuts these lines of force at right angles; a current is thus generated which is led off by the brushes in the direction shown by the arrows, still further increasing the magnetism of N and S, which, in turn, reacts on the armature core and coil until such a speed is attained that the electricity generated and flowing round M M M M completely saturates its iron cores and pole pieces with magnetism. Any further increase in speed will cause unnecessary heating of the electro-magnet coils, owing to the current passing through them being in excess of that required to saturate the cores and poles with magnetism.

Brush Dynamo.—In the Brush machine the armature coils are caused to revolve in a most advantageous manner, and as close as practicable to the poles of the electro-magnet, thus inducing great electrical energy (E × C) for a given speed. A reduction of the total resistance of the armature coils is made by cutting out of circuit two of them when in the least effective position. The commutator and its brushes are so placed upon the shaft, outside of the main bearings, that they can be easily got at for cleaning and repair, and are, therefore, more easily kept in good working order. The capability of generating currents of high electromotive force, with a mean current strength of 10 amperes, so that any number of lamps, from 1 to 40, may be worked in one circuit, in series, and the comparatively low speed at which the larger machines are to be driven, viz., 750 revolutions per minute for a 16-light machine are advantages.

The Brush system has been constantly at work at the well-known engineering works of Messrs. Mirrlees and Watson, and Messrs. Robert Napier and Sons for two years, where I find it has given great satisfaction, and it has lately been installed in Aberdeen and Dundee for their street lighting.

(TO BE CONTINUED.)

Underground Wires in New York.—A New York contemporary says:—"The Committee on Ferries and Franchises of the Aldermen of this city have presented to the Board a report on the petition of the New York Electric Lines Company for permission to lay electric wires under the streets. They recommend that the petition of the company should be granted, its operations, however, to be subject to the provisions of the ordinance regulating the laying of underground wires."

ELECTRIC LIGHTING AND LOCOMOTION.*

Forty-three years ago it was practically shown by Jacobi, on the River Neva, that locomotion by the aid of electricity was possible. No experiment, then, merely to prove this fact is needed at the present day. Nevertheless, both experiments and calculations are still necessary to convince the world that electric locomotion is not only possible but also commercially practicable. That electric transmission of power possesses great advantages—arising, first, from the small weight of the electromotor per horse-power developed by it; secondly, from the fact that large amounts of power can be transmitted through quite thin flexible wires—must also have struck any one who has ever seen a powerful machine driven by electricity. Its disadvantages are generally summed up in the single sentence that it is too expensive. But people, as a rule, do not trouble themselves to inquire whether it is really more expensive than other modes of transmitting power, and whether, if this be the case, it arises from some inherent defect in the principle itself, or merely from some removable imperfection in the machinery hitherto employed for the purpose.

At the present day the public may be divided into two classes—the one who thinks that electric locomotion and transmission of power will act as a sort of philosopher's stone, and solve all difficulties: the other, that it is a new fangled notion, and carefully to be shunned. The first class implores to be allowed to buy shares in any company that can in any sort of way have the word "electric" tacked on to its title, while the other buttons up its pockets at the mention of the word electricity, and busies itself with what it terms "something useful and practical." And, unfortunately, the repeated failures of the sanguine members of the first class to reach the El Dorado they have imagined to themselves only strengthens the belief of the more cautious members of the second class in their shrewdness and in the wise decision they fancy they have arrived at, that electricity is a mere will-o'-the-wisp.

But you, I am sure, will not have that opinion when you have seen to-night what can be done by electricity. I turn on this electric tap, and at once this fan commences to revolve rapidly, and sends forth a rush of wind. That, perhaps you will say, could as well be done by a belt driven by a steam engine: but I turn on another tap in the same supply wire, and at once the fan is lighted up by this electric lamp. That could not have been done merely by a steam engine. Again, a third tap; this electric fire burns, and the water starts boiling in this glue pot. [Experiment shown.] This thin flexible wire then furnishes a supply of electric power which can at will be used for producing motive power, light, or heat.

Now, to produce this supply of electric power, we must first have a steam engine, a gas engine, a water-wheel, or windmill to produce motion, and a dynamo machine to convert the mechanical energy into electric energy. These may be in the same room, or in another part of the building, or in another street, or away in the country; the electric power may be brought by a wire and used directly, or it may be stored in Faure-Sellon-Volckmar accumulators and used at some subsequent time, as I am doing now, thanks to the courtesy of the Electric Power Storage Company. Indeed, I may mention that in all my experiments I am using only stored electricity; and in this room, where we are utilising this supply of electric power, we must have an electro-motor if we want motion, an electric lamp if we want light, and an electric fire if we want heat. The transmission of power by electricity seems, then, very useful. Can it be made commercially remunerative?

As there are, doubtless, many in this hall who are deeply interested, either from scientific or from commercial reasons, in the answer to this question, and generally in the practical applications of electricity, it will be well to commence this lecture by considering, as shortly and as popularly as possible, what are the real difficulties besetting electric transmission of power, and what are the means electric engineers are proposing for surmounting them. Let us then attack the question together, not in the rosy, sanguine humour of the promoters of electric bubble companies, nor with the cold, hard scepticism of those who forget that with the early locomotive engines the fireman had to run along the road by the side and stoke, but as common-sense Englishmen who are anxious to know whether at the present moment the pros or the cons are in the majority.

An electric current, as you have seen, can produce heat; but, unfortunately, not only can an electric current produce heat, but an electric current always is producing heat. Now, while it is very proper that heat should be produced in an electric lamp or furnace, it is quite out of place in the dynamo machine or generator of electricity, or in the leading wires, or in the electro-motor, which converts the electric energy into mechanical energy. In all such cases the heat produced by the electric current corresponds with the heat produced by friction in machinery, and causes the same sort of waste of power.

But this loss of power, we shall see, is not necessarily so very great even when the power has to be transmitted a considerable distance, for when there are a number of machines, lamps, or motors that have to be worked by electricity there are two ways in which they may be connected together. They may all be joined in what is technically called "parallel," or they may be connected in "series." In the first case the current (as was illustrated by diagrams) that passes through any one of these machines does not pass through any other, and the generator must produce a large current—as large, in fact, as the sum of all the currents passing through all the machines. In the second case, the "series" arrangement, the same current of electricity passes through all the instruments one after the other in succession, and the generator only produces a current equal to that passing through any one of them. The ordinary methods of supplying houses with water or with gas are examples of the parallel system, because the water or gas that is supplied to any one house does not go to any other. The postman brings the letters and the boy leaves penny papers at a number of houses in parallel, while a copy of *The Times*, lent out at a penny an hour, is furnished to a neighbourhood in series.

And just as a newspaper or a book from a circulating library loses in freshness, although gaining in thumb-marks and dog-ears, when supplied to its readers in series, and as water loses head or pressure as it flows down a stream, so electricity loses its potential or power to work in passing through a number of machines worked by it in series.

To work, then, a number of electric motors or lamps in the multiple arc system we must at starting supply a large quantity of electricity at, it may be, only a low potential or pressure; whereas, if they are joined in series, the current may be small, but the initial pressure must be great.

In all electric railways and tramways constructed up to the present time the multiple arc system has alone been adopted. This you will see from the photographs that I will now project on the screen of all the most important electric railways yet constructed. First comes three photographs [Photos. on screen] of the small circular railway, 900 yards long, of 3ft. 3in. gauge, laid in the grounds of the Berlin Exhibition in 1879, and exhibited in 1881 at the Crystal Palace, Sydenham; next, a photograph of the Lichterfelde Railway, near Berlin; then the electric tramway in the Champs Elysée, Paris; and that of Charlottenburg, near Spandau. The latest electric railway, the one six miles long, now in course of construction at Portrush, near the Giant's Causeway, in Ireland, I shall reserve, as I shall have much to say about it later on in these lectures.

[Photographs were then exhibited of the various electric railways, which were described in detail.]

But the amount of power lost in heat when a certain definite amount of power is being transmitted through a given wire is very different, whether the multiple arc or the series system be adopted, because the heat produced per minute depends on the strength of the current used in the transmission and not in the amount of power transmitted. Indeed, it depends not merely on the current, but on the square of the current, so that if the current be doubled the waste of power becomes four times as great as before. Economy in electric transmission, therefore, requires small current, and, if much power is to be transmitted, small current necessitates high potential and the motors or lamps working in series. Similar considerations apply to the transmission of power by water; to obtain great economy high pressure is absolutely necessary. The accompanying tables, taken from Professor Perry's Cantor Lectures, show the amount of loss of power when different amounts are transmitted different distances by water at an united pressure of 700lb., and at 1,400lb. per square inch, as well as the amount lost when electricity is employed with a difference of potential between the terminals of the dynamo, first of 8,000 volts, secondly of 80,000 volts.

But high electric potential or pressure is generally considered to mean danger to life, and series working of machines or lamps has this disadvantage, that if from any accident the current is stopped passing through one it is stopped passing through all.

The danger arising from the use of high potential can be very much diminished if, instead of using the earth as part of our return circuit, we employ not only an insulated wire to convey the current, but also another insulated wire to bring it back again, and if in addition the current flowing through the whole circuit is not intermittent. This may be shown by the following experiment:—Attached to these wires, well insulated from the ground, are the insulated coatings of this battery of charged Leyden jars. Now, although the difference of potentials between the wires is some thousands of volts, far, far greater than is at present used, or proposed to be used, in any system of electric transmission of power, I can, as you see, touch either wire with perfect impunity. But if either of these wires be replaced by a wire in contact with the earth, say replaced by one of the gas pipes, and I were now to touch the other, I should receive a violent shock.

As, however, my love of electric experiments does not extend to shocks, I will touch the insulated wire by deputy, using this metallic rod, and the result is, you see, a bright spark. [Experiment shown.] Both the going and return wires, therefore, should be insulated.

But, next, the current flowing in them must not be discontinuous if danger is to be avoided. For if, instead of keeping the difference of potentials between any two points in the two insulated wires constant, I allow rapid fluctuations in this difference to take place, then, no matter how well the wires be insulated, a violent succession of shocks will be received on touching either of the wires, even although the other be not touched, so that no circuit in the ordinary sense is completed through the body. To show this experimentally I shall replace this insulated battery of Leyden jars with an induction coil, which, as well as the voltaic cells used in charging it, are thoroughly well insulated from the earth in every part. Let me, however, touch either of these wires—again by deputy—and you see bright sparks passing to the earth. [Experiment shown.] Bear in mind that I am touching one wire only, not both, so that, although the Ruhmkoff coil is doubtless an old friend to you, I am using it to-night in a new way to illustrate my point.

Now let us consider why it is that when a current goes and returns by a wire completely insulated from the ground no shock is experienced when the current is perfectly steady, even if a bare part of the wire be touched; but if there are rapid variations in the current strength severe shocks are felt even if only one part of the wire be touched.

In each case the effect of touching the wire is to reduce the potential of the point touched to that of the earth, and to effect a corresponding alteration of the potential along the whole line. This means the addition to a subtraction of a certain quantity of electricity from the wire. In the case of a perfectly steady current this operation only occurs *once* for once touching the bare wire, and unless the electrostatic capacity of the wire be very great, or the potential of the point touched immensely different from that of the earth, this *single* addition or substraction of electricity produces hardly any perceptible feeling. But in the case of a varying current the potential of the point would naturally be undergoing constant variations of potential, so that in order to keep the point touched at the same potential as that of the earth, constant additions and subtractions of electricity are necessary, and if these occur with sufficient rapidity a severe shock is produced, even although the body forms no part of the main circuit.

A single puff of air through this syren produces no audible sound, a rapid succession of even minute puffs a loud roar; so the single small electric discharge is not perceptible, but the rapid shower of Lilliputian arrows is terribly painful. This, indeed, is the same analogy Professor Perry employed in his lecture at the Society of Arts to prove the powerful action of rapidly recurrent effects in connection with our method of signalling to ships by means of sound waves sent through the water.

High potential, I have explained, is absolutely necessary for economy in electric transmission of power, and I hope I have also made it clear to you that, contrary to the received opinion, this high potential is not necessarily at all dangerous to life if the currents employed are not at all discontinuous. But the discontinuity of current we have to deal with is not merely the discontinuity that exists in the so-called reverse current machines. Even many dynamos, like the Brush, do not produce a really constant current, although generating a current of sufficient mean constancy to cause a perfectly steady deflection on one of the ordinary ammeters of Prof. Perry and myself, an instrument, be it remembered, so dead-beat that it records with perfect accuracy the change of current produced every time the joint in the driving-belt passes round the pulley of the dynamo, as well as the regular increase of current at each of the explosions of the gas in the cylinder of a gas engine.

The variations of current I am now referring to occur many hundreds of times a minutes, and although they cannot be detected by ordinary current meters, and although but little attention has been given to them, they are, in my opinion, a source of great danger when the dynamo produces a high electromotive force.

In any machine for the mechanical production of electricity a coil must, as you no doubt all know, be alternately rapidly brought up to a magnet and then withdrawn. Bringing up the coil produces a current in one direction in the coil, and withdrawing it a current in the opposite; and although by a simple piece of mechanism, called a commutator, the direction of the current in the external, or useful, portion of the circuit may be always kept the same, even although the direction of the current is alternately reversed in the coil no mechanism can make the coil produce a current at the moments of rest, when it changes its direction of motion. Wheatstone, in 1841, proposed to overcome this difficulty by combining two or more dynamos in series, like the two cylinders of a steam engine, in such a way that the current produced by the one was strongest when the current produced by the other was weakest; but Pacinotti, in 1860, showed us scientifically, and Gramme, in 1870, practically, how to combine a number of moving coils in one machine so as to give a current comparable in steadiness with that produced by a voltaic battery. The power of any dynamo depends roughly on the speed at which the coils move and on the strength of the magnetic field in which they move. Now, from the construction of the well-known Gramme machine, the strength of this magnetic field is necessarily weak when the machine is made of large size so that the greater power and efficiency which ought to come from enlarging the machine is partially compensated for by the relatively weaker magnetic field; indeed, even in a small Gramme machine the magnetic field is probably weaker than the magnetic field produced long ago in the old reverse-current machines of Holmes and Wilde. Hence more recent inventors, like Brush, have adopted a compromise between the perfect uniformity of strength of current obtained with the Gramme dynamo and the strong magnetic field in the old reverse-current machines. But in almost all the high electromotive force dynamos continuity of current has been somewhat sacrificed to strength of magnetic field. The plan, however, described in 1879 by Professor Perry and myself of oblique coiling of the armature, has enabled us, especially in our recently-constructed machines, to combine the continuity of current produced by a Gramme with the powerful magnetic field necessary for obtaining high electromotive force, and these results are in no way diminished when the machine is increased to the size necessary for utilising hundreds or thousands of horse-power and for obtaining that high efficiency which both theory and practice show is obtainable with the use of very large dynamos.

The next point to consider is how can we measure the amount of this dangerous discontinuity in the current produced by a dynamo without having to resort to the inconvenient process of killing off a certain number of people. We want a "discontinuity meter," and such an instrument I have here, employed by Professor Perry and myself for this purpose. It consists simply of an induction coil in which both the primary and secondary circuits are of thick wire. The one is put in the main path of the current, the other is attached to one of our "Spring Ammeters," which measures the mean square of the strength of the reverse currents produced in the outer secondary coil by the intermittencies of the main current.

Now, what are the results obtained when such an instrument is practically employed? Why, we find that when a current of ten amperes, produced by a three-light Brush dynamo, is flowing through the primary, there is a reverse current through the secondary which increases to about five amperes, when the secondary is nearly short-circuited, and which, be it remembered, is produced merely by the commonly ignored discontinuities in the current in the main current produced by the Brush machine. On the other hand, when the same current, ten amperes, is sent through the primary by a Gramme machine running at about the same speed, no visible current, certainly not a quarter of an ampere, is produced in the secondary. Hence it is clear that the continuity of the Gramme current is immensely greater than the continuity of the Brush current.

A telephone may also be used as a discontinuity meter, the two terminals of which are in different experiments attached to two points close together in the main circuit of the dynamo. For quantitative experiments these two adjacent points in the main circuit should be selected, so that in all cases there is the same difference of potentials between them, and then the pitch of the note heard in the telephone will tell the number of variations per minute in the main current, and the loudness of the note the magnitude of such variation.

And I strongly advise any one who is procuring a high electromotive force dynamo to ascertain for himself, before purchasing, the magnitude of the discontinuity factor of the machine, and about which he will find no information, as a rule, given in any description of the machine.

The other inconvenience arising from the use of high potential and small current, viz., that as the motors and lamps must be put in series the accidental stoppage of the current passing through one stops the current passing through all, is easily remedied by the use of what are technically called "cut outs." A cut out, as you see, consists of an electro-magnet wound with comparatively fine wire, and which allows a small part of the total current to pass through it instead of through a particular motor or lamp. If, however, from no failure in the generator, no current can pass through the motor or lamp, then more passes through the cut out, the electro-magnet of which becomes stronger than before, attracts the armature which closes this side circuit, and so allows all the current to flow by the bye-pass thus formed.

We have seen, then, that for economic electric transmission of power high potential must be used; secondly, to avoid danger to workmen and others likely to touch the wires, both the going and return wires must be insulated, and also the current must not only be what is practically called a constant current, but must not be subject to the rapid variations in intensity such as are produced by many existing dynamos.

Next, in a satisfactory system of distribution of power, be it electric or otherwise, the supply should be exactly equal to the demand: a greater or less demand for power on the part of any consumer should not be accompanied by a less or greater supply to any other consumer of power. In the distribution of gas to a town this problem has never been completely solved. Owing partly to the mass possessed by the gas in the mains no automatic regulator has ever yet been devised to use at the gas works so perfect that our burners do not flare at about nine o'clock in the evening, when the consumption of gas in the town is being rapidly diminished; and, indeed, at the present day a gas engine in a building even fed direct from the main will cause unpleasant pulsations in all the lights in the same building, also

Digitized by Google

fed directly and separately from the main, so that the number of explosions in the gas engine can be counted all over the building. The pressure regulator at the gasworks cannot act quickly enough, so that Sugg and others have devised automatic regulators to attach to the burners themselves in the houses.

Constant pressure in the case of gas corresponds for electric lamps or motors in parallel, with constant difference of potentials between the leads and with constant current for lamps or motors in series.

As an illustration of the importance of these considerations you see this battery of three Grove's cells will light this incandescent lamp, or, it will drive this electro-motor, but when I attempt to unite them in multiple arc together, the light of the lamp is, you observe, much diminished in intensity, due to the fact that the difference of potentials at the ends of the carbon filament is diminished when the motor is started. Again, I have these two lamps in series; I now allow the current to pass through a third lamp in the same series, and you observe that all the three are duller than either of the two were before, due to the current being diminished. [Exp. shown.]

And, conversely, if from a sudden diminution in the consumption, arising from many of the lamps being suddenly turned off, the difference of potentials between the main wires is much increased, all the remaining incandescent lamps are suddenly broken. Indeed, when the governing of the difference of potentials or of the currents was much less perfect than at present, it was no uncommon thing for hundreds of incandescent lamps, costing many pounds, to be suddenly broken.

Consequently, the problem of supplying either constant difference of potentials in the parallel system, or constant current in the series system, independently of the consumption of electric energy, and which might at first sight appear rather a dry and uninteresting problem, is in reality of great practical importance, since it must be solved before one train on an electric railway shall not suddenly start going faster because another has stopped, or before the electric lights in one train shall not become dim or break because the passengers in another train have turned theirs on or off. It is a problem, therefore, to which electrical engineers have devoted much attention during the past few years.

(TO BE CONTINUED.)

THE TELEPHONE CASE.

JUDGMENT.

We have already given the judgments of the Master of the Rolls and Lord Justice Lindley in this case. We now give that of Lord Justice Bowen, which ends our report so far as the details of the case are concerned:—

Lord Justice Bowen: I am of the same opinion. With regard to the questions which arise on the construction of the document, I confess that I think the case an extremely difficult one. I am not sure that there have not been times in the history of the Patent Law when documents worded not more obscurely than this have been upset; but I do think that applying the principles which have obtained in the construction of documents through, at all events, the greater portion of the history of the Patent Law, that one can see one's way clearly to disposing of this appeal in the way in which we have done. It would be wrong to disguise from ourselves or from those whose case we are deciding, that as regards the construction of the document we are deciding the case on what may be called the benevolent principle, the principle of which has been called in many cases the benevolent principle of construction, and that is the way Mr. Hunnings's powerful, and in some respects very difficult, argument is made out; and it is in order to answer him that I propose to say a few words on what I think, and I believe the rest of the Court think, about the benevolent principle of construction. It is for the last hundred years that that principle has been applied. It was applied as early, and for anything I know, applied before, but certainly as early as Windon's case in 1st "Turnbull;" and it has been applied as lately as Hinck's case, when the Master of the Rolls, in language which I read again because I think it will make clear the few words I am going to say about it, said. The Master of the Rolls in that case says:—"I am anxious, as I believe every judge is who knows anything about the Patent Law, to support *bonâ fide* inventors who have actually invented something novel and useful, and to prevent their patents being overturned upon mere technical objections or mere cavillings with the language of their specification so as to deprive the inventor of the benefit of his invention. This is sometimes called the benevolent mode of construction. Perhaps that is not the best term to use; but it may be described as construing a specification fairly with a judicial anxiety to support the invention, if it can be supported on a reasonable construction of the patent. Beyond that the benevolent mode of construction does not go." That seems to me exactly to define what the benevolent principle of construction is; and it is, in fact, no new principle. It is an old principle of the law applied to a very special subject matter. It is not the dispensing of charity to a patentee. It is not that the Court will, because they wish to favour him, make him a present of an impossible construction, giving to the words of the patent a construction which cannot be found there; but it is simply this—that if more than one construction is possible, they will, when the patent is a meritorious one—when an idea is a meritorious one, and when there has been complete discovery—because that must be remembered as an essential part of the condition upon which we act—when there has been a *bonâ fide* discovery by the patentee, they will put the more favourable of the two possible constructions upon the specification with the intention of making it good. That seems to be nothing more than the old principle of law that a benignant interpretation is to be put on the document in order to give it effect, if it is to be gathered from the surrounding circumstances that it was intended that the document should be effective. That sort of presumption in favour of the effective nature of the document meant to be effective has been drawn from both inside the document and outside the document. There are cases in which presumption is outside the document, and where it ought to be made in order to give it an effect which it was obviously intended to have. There are cases in which the presumption ought to have been made on the construction of the document itself. The benevolent principle applied to the Patent Law is really an application of the old doctrine of construction. It really only comes to this—that there has been a meritorious invention, that when the patentee has disclosed adequately to the public the nature of his invention, the Court will put themselves, for the purpose of construing the document, in this position—they will remember that the patentee is an honest man and a *bonâ fide* meritorious inventor; and in construing his patent we will assume that he was speaking as such to a public which was competent to understand what he said. So defined, it seems to me that there is nothing in the House of Lords' decision to which the Master of the Rolls has referred, and which extends that doctrine. It may be that in the House of Lords they had in that case put a somewhat unexpected reading on a particular document; but they did not or could not extend the principle which I have ventured, no doubt imperfectly, to express. And the reason of that is this—because the doctrine is a principle of construction, not of misconstruction. It is intended to guide to a reasonable interpretation, not to be an excuse for misconstruction. Therefore we begin by reading this specification in question by remembering that, if there are two reasonable possible constructions to be put upon the specification, the more favourable one is to be adopted, if we think that the invention is a meritorious one, and it has been a *bonâ fide* attempt to discover the exact nature of the thing. That being so, I confess that I feel no hesitation in applying it to the Bell receiver. I will not go through again the explanation of the construction which has been put upon the claim by the Master of the Rolls and by Lord Justice Lindley. Mr. Hunnings argued very powerfully that the claim was too large. In one reading -and, perhaps, in the main reading—his argument can hardly be honest, and I think on the most obvious reading it is too large. But that is not the question. The question is whether there is not a reasonable reading, although not so reasonable; and it seems to me that there is, and on that ground I think that the objection to this patent fails. But next we have to consider the question of infringement and the anticipation, and, in order to decide this properly, we have to make up one's mind what it is that Bell's specification claims as regards the receiver. I think that at all events these points are clear. In reading the description upon page 18, it says that, in the first place, the instrument offered to the public by Bell has got a receiver and transmitter; in the second place, the receiver is to be a plate, or may be a plate; in the third place, it is to be a plate at all events in front of the magnet, and attached in front and close to it, with a fixed circumference. The exact method of the fixture appears not to be material to discuss; and, lastly, the drawing is important because an instrument is shown in a way in which every workman can make it. You have, therefore, not only the luminous idea expounded, but the very instrument which enables it to be worked shown; and I do not hesitate to say that as far as I can judge a drawing in this kind of patent may be looked to just as much as anything else to see what is the instrument which the patentee has brought before the world. The explanation of the principle is not necessary. What he has to do is to show an instrument and show what is wanted. Applying that to Bell's receiver, it seems to me that there has been an infringement in both cases. In fact, Mr. Hunnings himself abandoned that part of it. But there remains the more serious part of the question, as to whether there has been an anticipation. As regards the Reis instrument, I think that one may pass over it lightly, for the reasons given by those who preceded me. But has there been an anticipation in what was done by Sir William Thomson at Glasgow? I am only going to say a few words about the legal test to be made here, just as I said a few words about the benevolent construction. There is no new law laid down in this case, nor can there be any new law. The law about anticipation is as plain as possible. I do not know a better *resumé* of it than that given in the Plympton case by the Master of the Rolls: "The inventor only escapes what constituted the monopolist construction if he is the first and true inventor, and if the manufacture which he puts forward is not in use at the time of the alleged invention." Now we have not got to consider the question of use. But we have to consider when Bell's patent was out, and the person who is clothed with his rights is entitled to say that an invention is mine. An invention is not made if all that is done is to put forward an idea which was not in the stock of public knowledge before, and where there was only a pretence to sell it to the public in return for the monopoly. That really renders the issue very simple. Has there been a previous publication of the same thing? In discussing that question, application really means exactly as much and no more than it does when we are dealing with the publication of the specification itself. Has there been a publication of the same thing at Glasgow, and has it taken an effectual and practical shape? Has the contribution to the world's knowledge been substantial? I take it what I consider to be good law (not perhaps as applying in every single word to this instrument, but as embodying the principle by which we test the cases of previous publication) as laid down by the Lord Chancellor when he used this language:—"On principle I conclude that a prior knowledge of the invention to veto a patent must be knowledge equal to that required to be given by a specification, or rather such knowledge as will enable us to conceive the very discovery, and to carry the invention into practical use." Now, what are the facts? Sir William Thomson came to the British Association. He came with an instrument, and he showed that instrument to the British Association, and he allowed the instrument to lie not only on the table, but in the laboratory of the Glasgow University for some time; and it is unquestionable that everybody who chose could see it, and there is evidence that many did see it, and that many did appreciate it, and attach as they could their own ideas to it, and perhaps rightly, and perhaps reasonably they appreciated what was shown to them, because we had not only accounts given in contemporary publications of the instruments as seen, but also we have drawings more or less imperfect, but still substantially representing what was visible. Now I think it would be almost childish in any one who sends an instrument to the British Association to say that he did not intend it to be a publication of some sort; and what is the publication that he intends? Why the instrument that he sends. A man does not send an instrument to the centre of the scientific world to be shown to the scientific men of this country without intending that they should see what they saw, and without intending to make a present to them of what he sends. I think there was a publication, and the question is of what? Was it a publication of the Bell instrument, or, rather, was it a publication of an instrument substantially the same as Bell's, or which by an ordinary

Digitized by Google

workman could be turned into a Bell instrument? As shown to the world at Glasgow it had unquestionably a lid. I find that on the evidence there was an unmistakable crease. If I had to say as to its sound I should say it had some, not so much as at present. But still I will not decide this case on the assumption that there was a crease at Glasgow. What is said is that it had not got the adjustment which the Bell instrument has got. It was to be worked on the same electrical principle, no doubt. In the first place, it was not identical in appearance, and it was not the same to look at. It was argued in the court below, and was contended at one time before us, that the Glasgow instrument as shown at Glasgow was of no utility. I think that that was a false point if pressed to that length in the court below, because we have seen it work, and know that it works well under certain conditions. We know, now, that it is not true that the Glasgow instrument cannot be made to speak even in its present shape. I do not feel driven to an assertion one way or the other as to whether, in considering the question of utility of the Glasgow instrument, one must judge solely of what was known at the time or since. It seems to me that neither is exactly right, because I can conceive an instrument being useless at the time when its use was not known, but which afterwards became useful. The difficulty would be one for the tribunal to decide; but it would not be a difficulty of law. Again, I can conceive an instrument being useful at one time, and which ceased to be useful. That is not a difficulty in the law, but it may be difficult for the tribunal to decide. But I do think it is clear in judging of the two instruments, and making up one's mind whether the Bell is substantially the same as the Glasgow one we must take care that the conditions under which we judge one and the other are the same, because otherwise there is no such thing as comparison. You cannot compare two things except under fairly similar conditions. There is no doubt some complication introduced into the Patent Act, but down to the time of this trial in this court, and, as far as I know, up to the time of the trial in Mr. Justice Fry's court, the Glasgow instrument never was tried with any except the old transmitter at the time that Sir W. Thomson gave his evidence, and I believe the other witnesses, or some of them, had not seen the Glasgow transmitter under very favourable conditions. We have tried it under favourable conditions; and we know, under more favourable conditions, it works nearly as well as the Bell receiver. That does not seem to me to help the appellants. We come back to ask the question—Would the ordinary workman, when that Glasgow instrument was presented to him, have turned it into the Bell by the exercise of no more than ordinary and reasonable skill without the incitement of invention? because you have nothing to do with the invention of a workman, but must take his ordinary knowledge. It seems to me that the ordinary workman would not have turned it into the Bell, and for this very reason, that the Bell presents a complete adjustment, and the Glasgow instrument did not. Now, it is all very well to call a complete adjustment nothing. In many a patent case, no doubt, an adjustment is nothing more than that. But the fallacy seems to me to be that in a very obscure subject, at a moment of time when knowledge was limited, it was impossible that "mounting" could be disposed of by calling it simply "nothing." The condition in which the Glasgow instrument was presented at Glasgow was such as to give no indication at all to those who saw it as to what was the best adjustment or the best way to use it. In dealing with the subject of electricity, at the present moment it is so obscure that I am not sure that scientific men would say positively as to how the transmitter works; and, going back six years, into the very twilight of the discovery, no one would say that an instrument which presented no means as to what was the best adjustment is the same instrument which shows it. I agree, in considering this question, one must endeavour to see whether there was a crease at Glasgow, or to make the case clearer to show that there was a crease in the Glasgow instrument. If there was a crease, it seems to me that that was obviously misleading, because the "crease" would prevent the lid from being drawn in the ordinary way. "If there was no crease, well, then, at all events," say the appellants, "if proper strength was applied in the current the lid would fall." Aye, if proper strength was applied, and if people knew as much about it as they do now. But they knew nothing about it then, practically, except that it would work, and they knew not under what conditions, and still less by what conditions it worked best. And the best reason for thinking that the ordinary workmen would be put off the scent is this—that Sir Wm. Thomson, the first authority, was put off the scent himself. Let us go back one moment to consider what is material in the various points of adjustment indicated by the Bell patent. We are told there is a plate in front; and it is to be attached to something. We are told that it is close to the main: and we are told what the circumference is to be; and, lastly, there is a drawing. Can any reasonable man believe that if Sir Wm. Thomson had been told all these special particular facts at Glasgow, that in the attempts to make the instrument work feebly and badly, though it might work better, he would not have been assisted. I come to the conclusion that he would have been assisted; and that seems to me sufficient in this case, where the *onus* lies upon those who seek to upset a *bonâ fide* patent, that it establishes a proposition urged in reply that there has been no such complete anticipation at Glasgow of the same instrument in as practical a shape as is necessary to make out that the enrichment of the stock of knowledge of the world which the Bell instrument, upon the confession of the respondents, has made.

SUBMARINE TELEGRAPH COMPANY.

The half-yearly general meeting of the proprietors in this Company was held at the offices, Throgmorton-avenue, London-wall, on the 21st inst., under the presidency of Sir James Carmichael, Bart.

The SECRETARY (Mr. S. M. Clare) having read the notice convening the meeting, the seal was affixed to the register of shareholders, and the report of the directors was taken as read.

The CHAIRMAN said: I have much pleasure in moving the adoption of the report and accounts before you, which, I trust, you will find satisfactory, though we have not been able on this occasion to recommend quite so large a dividend as at the last half-yearly meeting. This is very easily accounted for: in fact, I think by looking at the report you will see that one of the principal items in the increase of our expenditure has arisen from the repair of cables. Those repairs last year have been rather onerous owing to the very exceptional state of the weather. We have had a series of storms and gales, which not only caused damage to our cables, but also very much delayed the operations of our engineer in carrying out the necessary repairs. In the North Sea for the last two or three months there has not been sufficient interval of calm weather to do any constant work. When the engineer has been on the ground after a few hours' work he has been compelled to seek shelter in Lowestoft or some neighbouring port. That fully accounts for the extra expense of the cables, but that is one of those circumstances which submarine telegraph companies must be subjected to, and over which directors can have no possible control. Notwithstanding these drawbacks, our traffic would have been considerably better than it is had it not been for the unsettled state of politics in France, which, no doubt, as you are all aware, has prevented to a large extent not only speculation on the Bourse, but to a certain extent has paralysed all commercial enterprise in the country; in fact, you saw that from the late deputation of merchants and others who waited on M. Grevy, with the view of improving matters. Everything that affects the French Bourse affects us, and diminishes our traffic, because they are our best customers. However, notwithstanding the difficulty that we have had to contend with, I do not think that the traffic, as traffic, has been at all bad, for I find the figures show that during the past half year we carried no fewer than 1,422,178 messages. That is not at all a bad half year's business, and it is 69,352 messages in excess of the number transmitted in the same period of last year. Every one knows that an increase of telegraph messages does not necessarily mean an increase of profit. Still, this shows a steady increase, which, as I have said, would have been much larger, but for the circumstances I have mentioned. I think I have, as far as is in my power, accounted for this diminution of one half per cent. in the dividend this half year. Looking forward to the future, I am able to give you some little encouragement, for what I consider a very important feature has just occurred in the working of this Company's business—that is to say, in the Press wires. We lease special wires to the Press, but hitherto that has been confined to the English newspapers. Three of our principal English newspapers are all customers of ours—*The Times*, the *Daily Telegraph*, and the *Standard*—and they have all special wires from us. Now, I am happy to say that the foreign Press, who have never paid to any great extent for telegraphic news, are now coming forward, and we have just concluded an arrangement with *La Reforme*, which is the property of a very enterprising barrister in Paris, who has lately started this paper, and has made arrangements with us for the lease of a special wire. That is a very important feature, and this arrangement is almost certain to lead to others of a similar nature. Indeed, we have already an application respecting another journal. I hope in the course of the next few months that we may see the system of leasing our wires to the Press still further developed. I do not think that I have any further observations to make, but I shall be happy to answer any questions as to the report or accounts.

Mr. C. N. BOYS seconded the motion, which was carried unanimously.

The CHAIRMAN: I have great pleasure in proposing "That, in accordance with the recommendation of the court of directors, the dividend for the half year ending 31st December last at the rate of 18½ per cent. per annum, less income tax, on the capital of the Company be declared, and that it become payable on and after the 1st of March next."

Mr. CAPPER seconded the motion, which was carried unanimously.

Mr. CASTLE SMITH desired to call attention to the subject of the reserves. When he first joined the Company it struck him that the reserves were too small, and that having regard to the capital and the short period that they had to run they would do well to increase the reserves. On the former occasion the reserve had been for a short time 5 per cent. on the gross receipts, and he suggested that it should be 10 per cent., and after friendly consideration and discussion on the subject his suggestion was acted on. On the present occasion, he ventured to submit that the shareholders would be consulting their interests still more if they were to put 15 per cent. to that fund instead of 10 per cent. They had only now a short time to live, unless by-and-by they should have their monopoly renewed. But, assuming that that was not the case, he believed that they had about six years to run, which was only a very short time in which to build up their interests. His opinion was that putting by 15 per cent. of their capital would place them in a very improved position, especially with regard to their future. He believed that if his suggestion were acted upon it would not interfere with their dividend, and that, therefore, they would not suffer in the present, while as regarded the future they would be greatly benefited.

The CHAIRMAN: I am sure we are all very much obliged to Mr. Castle Smith. I consider what he has said is exceedingly good sense, and must commend itself to every shareholder. I have always been in favour of putting by the largest possible amount to the reserve fund, and I was opposed to its being reduced as it was some years ago, and I am happy again to see it at 10 per cent. If, however, the shareholders wish to increase that to 15 per cent. we should be very glad. The more you can put by the better; but, at the same time, there are some shareholders who wish that everything earned should be divided. This is a matter quite for yourselves to decide. I would point out that we could do nothing at this meeting.

Mr. CASTLE SMITH observed that he would suggest that what he had said be regarded as a motion, which should be seconded and dealt with in the usual way.

Mr. CAPPER: As a recommendation to the directors to take it into their consideration?

The SOLICITOR (Mr. Campbell) stated that the resolution was not one which they could pass to have legal effect, but it should be treated in this way, that if the opinion of the shareholders was that 15 per cent. should be put aside the next time, 15 per cent. would be put aside in the next accounts, and if those accounts were then passed it would be done again. If, however, the shareholders would not pass the accounts next time with 15 per cent. in the statement the matter would fall through.

Mr. CASTLE SMITH expressed himself satisfied if the course indicated by the solicitor were acted on.

Mr. CAPPER said he would second the motion if by making the sacrifice of a large dividend they would be greatly benefited.

Mr. RINGS would not express an opinion in any way as to the advisa-

Digitized by Google

bility of the step proposed, but suggested that it would be better to leave the question till their next meeting, and then for the directors in issuing their next report to say that in consequence of a desire expressed by some of the shareholders that the reserve fund in future should be 15 per cent. a resolution on that, the next occasion, would be moved to that effect. That would give all the shareholders an opportunity of expressing an opinion on the subject, but he thought it would be altogether hasty to make such a considerable change without giving all the shareholders an opportunity of considering it.

The CHAIRMAN thought that the effect would be very much the same acting on either course.

The Hon. ASHLEY PONSONBY observed that as a director he would prefer that it be regarded entirely as a shareholders' question, and that a resolution should be put instructing the directors to open the question at the next meeting. He quite endorsed what Mr. Smith had said as to the advisability of having a strong reserve fund. Towards the end of their concession they would find it very greatly strengthened, and be put in a much better position, while the market value would also be increased. But at the same time he thought that the shareholders should give an instruction to the directors as to putting 15 per cent. to the reserve in the next report.

Mr. SMITH remarked that the question might then be argued on the report.

The Hon. A. PONSONBY assented, adding that it would not involve any dispute as to the accounts.

Mr. RINGS said that the increase from 5 to 10 per cent. which was moved on a previous occasion, he considered very reasonable indeed, but he thought it might be a question with many of the shareholders whether they might not think that taking 15 per cent. out of the gross profits was going too far, therefore he suggested that every shareholder should have an opportunity of expressing his opinion. He asked whether some confusion would not be created in the accounts if 15 per cent. were deducted, and then the shareholders did not assent to the proposal.

The SECRETARY replied in the affirmative.

Mr. RINGS moved as an amendment, "That the further consideration of the subject be adjourned to the next half-yearly meeting."

The CHAIRMAN, in reply to a question, stated that at the expiration of their monopoly all their property, including the wires, would belong to the Company. The cables, too, were in excellent order, and they would be a very valuable property should they be sold at the end of the six years, and he admitted that in keeping their cables in an efficient condition they were strengthening the reserve.

Sir THOS. DAKIN, reverting to the proposal to increase the reserve fund, said it was one as to which the shareholders generally should be consulted. He seconded the amendment.

The CHAIRMAN said that the resolution which had been moved was to the effect that 15 per cent. should be included in the next report as the appropriation of the reserve fund and shareholders might then accept or reject it. If they adopted the resolution, and the shareholders did not approve the increase of the appropriation to the reserve fund, it would throw the accounts into confusion as they would have been prepared with the view of putting 15 per cent. aside. He was in favour of adding to the reserve fund, but he thought it would be better to act on the amendment so as to give all the shareholders notice, when it might be discussed at the next meeting, and if they approved it it would be adopted at once. After some further discussion on the point the amendment was passed as follows: "That due notice be given to the proprietors in the next half year that for the future 15 per cent. of the gross receipts as from the first of January, 1883, be added to the reserve fund, instead of 10 per cent."

A vote of thanks to the chairman concluded the proceedings.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).

Report of the directors to be submitted to the members at the nineteenth ordinary meeting, to be held on Tuesday, the 27th day of February, 1883, at one o'clock precisely. The directors have the pleasure to submit their nineteenth annual report to the members. The accounts for the year show a net profit of £92,260 13s. after charging the interest on the debentures. To this sum must be added £60,394 12s. 9d. brought forward from last year, making a total of £152,655 5s. 9d. From this amount is deducted the interim dividend of 5 per cent., paid July 18th, 1882, amounting to £22,410, leaving £130,245 5s. 9d. to be dealt with. Of this sum the directors propose to distribute a dividend of £1 16s. per share, absorbing £67,230, being at the rate of 15 per cent., and making, with the amount already paid, a total dividend for the year of £2 8s. per share, free of income-tax, leaving £63,015 5s. 9d. to be carried forward to the next account. The operations carried out during the year 1882 have been as follow:—(A) In the early part of the year a cable 550 miles in length was laid, under a concession from the Austrian Government, between Corfu and Trieste, forming part of the Eastern Telegraph Company's system. (B) The German Union Telegraph Company's cable was repaired, in the North Sea, between Lowestoft and Greetseil. (C) The laying for the German Union Telegraph Company of a cable between Valentia, in Ireland, and Greetseil, in Germany, amounting to 776 miles, was completed in April. (D) 254 miles of cable were manufactured for the Western and Brazilian Telegraph Company, and laid in April between Ceara and Maranham, on the Brazilian Coast. The Brazilian Submarine Telegraph Company's cable, off Pernambuco, was at the same time repaired, and the shore end relaid. (E) Between the months of May and September extensive repairs were effected in the Anglo-American Telegraph Company's French Atlantic cable between Brest and St Pierre, in depths up to 2,000 fathoms, after a submergence of thirteen years. (F) In the month of August the Eastern Telegraph Company's cable between Porthcurno and Lisbon was repaired in a depth of 2,700 fathoms, and a cable for the same Company (234 miles in length) was manufactured and laid between Malta and Tripoli in October. (G) During the month of October the Brazilian Submarine Telegraph Company's cable between Lisbon and Madeira was duplicated, 663 miles of cable having been manufactured for this purpose; and the Lisbon shore end of the original cable was relaid. (H) A cable, 965 miles in length, has been manufactured for the Eastern Extension Telegraph Company, which will be laid in the China Sea between Hong Kong and Shanghai. The factories at Wharf-road and at East Greenwich, together with the Company's ships, are in efficient working order. The steamship "Calabria" was chartered by the Government for several months during the year for the conveyance of troops and horses to and from Egypt. The retiring directors are Lord Alfred Paget and Mr. G. W. Campbell, who, being eligible, offer themselves for re-election. It will be necessary for the meeting to appoint auditors for the ensuing year. Mr. John Gane (of the firm of Messrs. Gane and Jackson) and Mr. James Glegg (of the firm of Messrs. Quilter, Ball, and Co.), who retire, offer themselves for re-election.

THE LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (Limited)
(RIVER PLATE and BRAZIL TELEGRAPH COMPANY).

NOTICE is hereby given that the HALF-YEARLY COUPONS which fall due on the 1st March, 1883, of £100,000 Seven per Centum Debentures of the River Plate and Brazil Telegraph Company will be PAID by Messrs. Glyn, Mills, Currie, and Co., 67, Lombard-street, in the City of London, bankers, on and after the 1st day of March, 1883, less income-tax. The Coupons must be left with Messrs. Glyn, Mills, Currie, and Co., for examination three clear days before the same can be paid.

By order,
WM. PAYTON, Secretary.

No. 66, Old Broad-street, E.C., London,
22nd February, 1883.

CALCUTTA INTERNATIONAL EXHIBITION.

THE MACHINERY and HARDWARE MART (CALCUTTA).

The Proprietors (one of whom is a Member of the Working Committee of the Exhibition) are prepared to receive consignments of MACHINERY, HARDWARE PAINTS, and all classes of Goods used by GOVERNMENT and MUNICIPAL ENGINEERS, MILLS, COLLIERIES, MINES, BREWERIES, &c., &c.

Full particulars on application to the London Agents,
Messrs. ALEX. LAWRIE and CO
14, St. Mary-axe, E.C.

INVENTORS of DYNAMOS, ACCUMULATORS, &c., can have Aid of large Engineering Works, Foundry, Skilled Men, and all Appliances in London; or can acquire the same, provisionally or otherwise, for a small outlay. Suitable for an Inventor or small Company.
For address apply, "S.," Messrs. PAYNE and CO.,
18, Cullum-street, E.C.

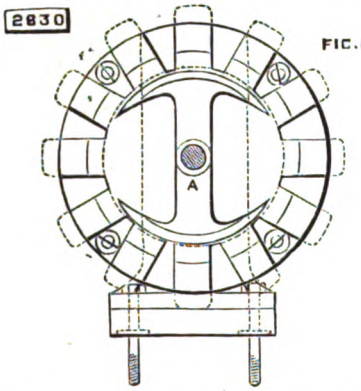
RECENT INVENTIONS.

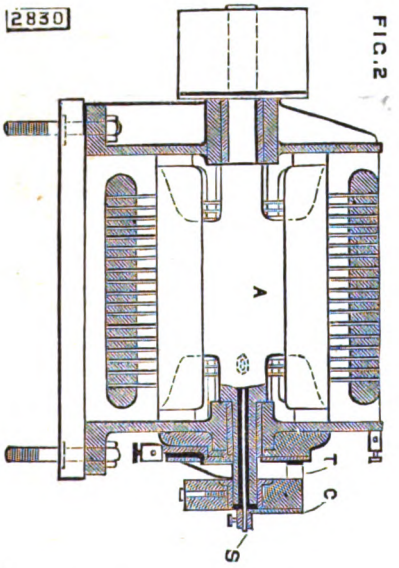
ABSTRACT OF SPECIFICATIONS.

830. Improvements in the Construction and Government of Electro-motors, &c., *Professors W. E. Ayrton and J. Perry, Finsbury.*—15*th June*, 1882. 8*d*.

One form of the invention is shown in Figs. 1 and 2. A is a rotating field magnet formed of soft iron or other material and wound with wire in coils, which are nearly parallel to the axis. This rotates inside a Pacinotti ring. In the



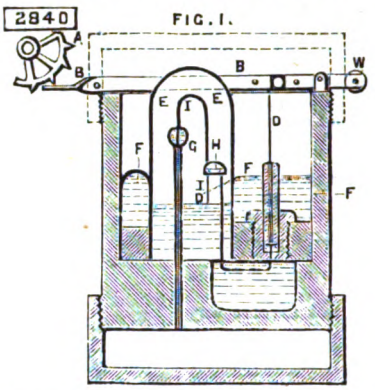
present case one end of the wire on the bobbin is fastened to the iron, and the other end passes insulated through a hole in spindle S, where it is connected to one of the rubbing brushes T. There are twelve coils on the ring, and their rods



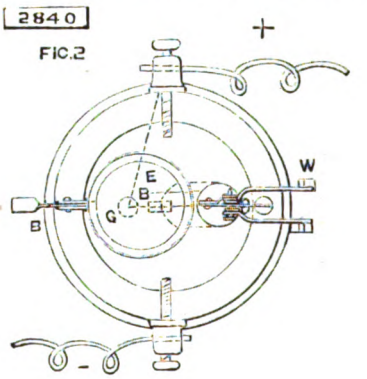
are joined up to the pieces C of the commutator as in the Gramme ring. In addition to the above machine, the inventors claim an arrangement by which the relative positions of the brushes and field magnet may be altered; another arrangement by means of which the relative positions of the commutator and the Pacinotti ring may be altered, &c., &c.

2840. Apparatus for the Measurement and Regulation of Velocity, *H. S. Hele Shaw, Bristol.*—16*h June*, 1882. 6*d*.

According to this invention the moving body, whose motion is to regulate that of another, imparts impulses to one end of a lever or frame, the other end of which communicates with a space from which oxygen and atmospheric impurities are excluded, a suitable purified gas being substituted. This space is separated from the outer air by mercury, through which a portion of the lever or frame, or a wire attached thereto, passes, and in which it works without appreciable friction. In the isolated space, but insulated from the mercury below, is a capsule of mercury, in which the wire attached to the lever dips at every impulse, and thus establishes electrical communication between the two portions of mercury, and so with two wires communicating with a motor whose motion is to be regulated; thus oxidation of the electrodes is almost altogether prevented.



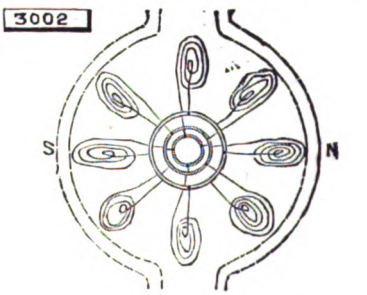
Figs. 1 and 2, which are sectional and plan views of the apparatus, taken with the above description, will explain the invention. A is the escapement wheel of a standard clock, whose motion is to regulate that of another body. B, the lever;



D, platinum wire passing into space filled with purified gas, E; F, mercury separating E from outer air; G, capsule of mercury; H′, glass junction, joining wire D with wire I, one end of which dips in G.

3002. Improvements in Dynamo-electric Machines, *P. Jensen, London.*—24*th June*, 1882.—*(A communication from D. A. Schuyler and F. G. Waterhouse, New York.)* 8*d*.

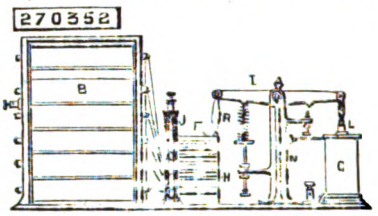
This relates to a novel arrangement of armature coils, &c. The coils are divided into sets of four, those in each set being disposed symmetrically with relation to one another in such a way that each coil of a set is placed at an angle of ninety degrees from its two neighbouring coils in the same set, and diametrically opposite the re-



maining coil of the set. Each set is provided with a separate commutator ring, and one end of each helix in a set is connected to a separate plate of the commutator. With the arrangement of field of force poles employed, diametrically opposite bobbins would be connected to diametrically opposite segments. The remaining ends of the coils are connected or in permanent electrical connection with one another. Commutator brushes are so applied that each bobbin is connected to the brush during its movement from one neutral point to the other. The figure illustrates the manner of dividing and connecting the bobbins to one another and to the commutator.

270,352. Device for Controlling Electrical Currents, *Charles J. Van Depoele, Chicago, Ill.*—*Filed July* 27*th*, 1882.

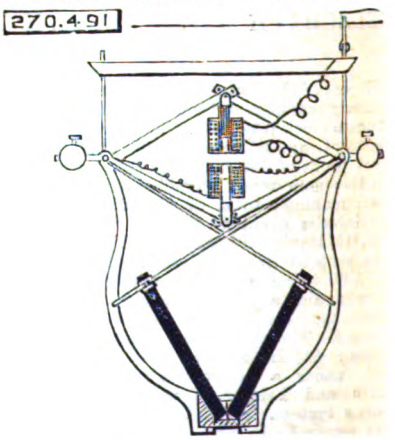
Claim.—(1) The coils B, permanently connected at their outer ends to one of the branch conductors of a multiple arc circuit, and a corresponding series of superposed insulated contact pieces F, each connected to the inner end of one of said coils, and provided with contact points H, and a support, J, provided with adjustable downward acting spring and suitable set screw, in combination with the lever I, provided with link R, electrically connected to the upper one of said contact pieces, the solenoid G, permanently connected to the other conductor of the branch, the core L, and suitable



wire connecting said solenoid and lever, and adapted to elevate or depress said core and lever to separate or connect the contact pieces F, and thereby regulate the branch current passing through the device in response to the fluctuations of the main current, substantially as set forth. (2) In combination with the wires of the external circuit the coils B, contact pieces F, and support J, the solenoid G, standard N, lever I, core L, and suitable connecting wires, all located in and forming part of a branch of a main circuit, an adjustable stop, a regulating tension spring connected to the stop and the said lever I, and suitable adjusting screw, substantially as shown and described.

270,491. Electric Light, *H. A. Seymour, Washington, D.C.*—*Filed June* 1*st*, 1882.

Claim.—(1) The combination, with the carbons of an electric light, of blocks of refractory material, against which the carbons rest, or which serve to support the adjacent ends of the carbons, and devices for automatically separating the blocks by the action of the current, substantially as set forth. (2) The combination, with the carbons of an electric light, of blocks of refractory material, against which the carbons rest, or which serve to support the adjacent ends of the carbons, and devices for automatically moving the blocks toward and from each other by the action of the current, substantially as set forth. (3) The combination, with the carbons of



of an electric light, of blocks for limiting the lengthwise movement of the carbons, and devices for automatically varying the distance between the adjacent ends of the carbons, substantially as set forth. (4) The combination, with the carbons of an electric light, of blocks for limiting the feed of the carbons, a solenoid in the main circuit for separating the blocks, and a solenoid in a shunt-circuit for causing the blocks to approach each other, substantially as set forth. (5) The combination, with the carbon, of an electric light and blocks of refractory material for supporting the adjacent ends of the carbons, of arms having said refractory blocks removably secured to the adjacent ends thereof, and electro-magnets for automatically regulating the distance between the end of the carbons, substantially as set forth.

SLIP

South America.—The cable between Callao and Mollendo is interrupted.

South Australia.—The postal statistics show the receipts for telegrams in this colony to be £42,000 per annum.

Direct Spanish Telegraph Company.—This company's direct cable communication with Spain, *viâ* Bilbao, is now fully restored.

Electric Lighting on Ships.—The steamer "Kate Adams," which plies on the Mississippi, is lighted by means of the Edison system.

Channel Islands.—Telegraphic communication with Guernsey is now restored. The cable between Guernsey and Alderney, however, remains interrupted.

Venezuela.—The land lines in Venezuela being interrupted, telegrams for that country can only be forwarded by way of the West Indies, and thence by post.

Royal Society.—On Thursday last Dr. Frankland, F.R.S., was to read a paper before this society entitled "Contributions to the Chemistry of Storage Batteries."

Royal Institution of Great Britain.—Last night (Friday) Mr. C. Vernon Boys was to read a paper before this institution on "Meters for Power and Electricity."

Electrical Exhibition at Philadelphia.—The Franklin Institute of Philadelphia, U.S.A., give notice of their intention to hold an electrical exhibition in that city during this year.

Provisional Orders.—The applications for provisional orders under the Electric Lighting Act in respect of Rochdale and Stalybridge have been thrown out on standing orders.

The Edison System in Europe and America.—Up to the 20th December last 29,192 Edison lamps were in use in America. Up to the commencement of February 19,536 lamps were in use in Europe.

New Book.—We have received a copy of a translation from the French of the Count du Moncel's excellent little work on the construction of electro-magnets, by Mr. C. J. Wharton. The book is published by Messrs. Spon, of Charing Cross, S.W.

Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ending 23rd February, 1883, were £2,276, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

New Company.—The Sperry Electric Light Motor and Car Brake Company of Chicago has recently been organised with a capital of 1,000,000 dollars, to work the inventions of Mr. Elmer A. Sperry in electric lighting and the application of electricity to motors.

An Explanation.—The Electric Carbon Storage and Apparatus Manufacturing Company wish us to explain that the Electric Carbon Company, referred to in our last issue as likely to be shortly wound up, is in no way connected with them, but is an entirely separate company.

West India and Panama Telegraph Company.—The estimated traffic receipts of this company for the half month ending the 15th February are £3,267, as compared with £2,983 in the corresponding period of 1882. The November receipts, estimated at £2,700, realised £2,707.

Society of Telegraph Engineers.—At the next meeting, to be held at 25, Great George-street, on Thursday, March 8th, at 8 p.m., a paper will be read "On Some New Forms of Telephone Transmitters, with a Note on the Action of the Microphone," by John Munro, associate.

Electric Lighting in Paris.—The Magasin du Printemps, in Paris, which was destroyed by fire about two years ago, has been rebuilt on a magnificent scale, and will shortly be opened. It will be lighted on the Jablochkoff system. Three hundred and fifty lamps will be employed.

Electric Lighting in Russia.—The Edison system is in use in the saw mill of M. Johnson at Yväskylä, in Russia. Forty lamps and an E dynamo constitute the plant at present. This is probably the most northerly point to which electric lighting has penetrated as yet; it is between the 62nd and 63rd degrees of latitude.

Electric Lighting for Newington District.—The *Gazette* of Tuesday last contains a notice from the Vestry of Newington, S.E., that they have applied to the Board of Trade for a license under the Electric Lighting Act, 1882, to supply and distribute electricity for public and private purposes in the parish of St. Mary, Newington.

Electric Lighting at Brunn (Austria).—The installation on the Edison system at Brünn Theatre was examined a day or two ago by the archduke. The machines were all set going for the occasion, and everything explained in detail by Mr. Francis Jehl, who has charge of the work. The archduke expressed great satisfaction with the lighting arrangements.

Telegraph Extension in Canada.—A line of Government telegraph is to be constructed from the present crossing of the south branch of the Saskatchewan River to Prince Albert. The promise to do this is, however, says the *Colonies and India*, made conditionally on the residents in the districts to be benefited contributing the required poles for carrying the wire.

To be Wound Up.—The Brush Electric Light and Power Company of Australasia is to be voluntarily wound up. It has sold all its patent rights to the Australasian Electric Light Power and Storage Company. Creditors should send in their claims before the 10th April to the liquidators, Mr. F. S. Isaac, 22, Great Winchester-street, E.C., and Mr. C. L. Wade, 18, Old Broad-street, E.C.

Prevention of Twist in Cables—A patent has recently been taken out by Mr. G. E. Vaughan for foreign inventors, in which a means of preventing the twisting asunder of cables when being made or laid is described. The inventors propose to wind the insulated core with alternate left and right-handed layers of yarn, one over the the other. The patent is dated 4th July, 1882, No. 3142.

M. Deprez's Experiments.—At the meeting of the French Academy of Sciences on the 19th February, M. Tresca read a paper on the recent experiments by M. Deprez at the workshops of the Northern of France Railway, when he resumed the Miesbach-Munich experiments in the transmission of power by means of electricity. According to M. Tresca, a machine of 6·31 h.-p. installed in the Northern Railway Station actuated another machine by a current transmitted through 8,500 metres of wire. The power received on the brake was 2·03 h.-p., and the return was consequently ·326.

Sunderland University Extension Classes.—The report of the examiner on the results of the recent course of

Digitized by Google

lectures on electricity and magnetism in connection with the University Extension Classes in Sunderland is very favourable. He states in his report "That for a scientific course of lectures to university students the syllabus scarcely admits of improvement." Nineteen students entered for the examination, and of these seventeen passed. Seven were recommended for special distinction—these were John Burns, John H. Cox, Edith Edmunds, G. A. Lax, G. H. Shevill, Maria Stephenson, and William F. Vint.

The Maxim-Weston Electric Company.—Rumour has of late been busy in City circles with the name of this company. Amongst other things we have heard it whispered that the shareholders are not over satisfied with the way in which the business of the company has been conducted, and that they have or will appoint a committee of investigation. The company certainly has not had an air of prosperity about it lately, in fact it seems to have lost the vigour it once had. There must be a reason for this. We have no doubt that the committee of investigation will arrive at a satisfactory solution of the reason why the company has made so little headway recently.

Underground Wires in New York.—According to a New York contemporary, the Western Union Telegraph Company have decided to begin in earnest the work of putting all the wires of the company in this city underground. The first underground main will extend from the company's building at Broadway and Dey-street, up Broadway to 23rd Street. The wires, it is said, will be laid in a tube large enough to contain 200 wires. The contract for this primary line has been given out, and work upon it will begin, it is promised, as soon as the weather will permit. The right to use the streets for this purpose was secured a few years ago. It is promised that, if the undergound system adopted works well, it will be extended to all parts of the city.

Electric Light for H.M.S. "Malabar."—We recently described and illustrated the method that had been adopted by the Swan United Electric Light Company in fitting up H.M.S. troopship "Himalaya" with their lamps. A sister trooper, H.M.S. "Malabar," is also to be lighted by incandescent lamps, the work in this case having been given to the Edison Electric Light Company. The total number of lamps to be employed will be 104 A or 16-candle, and 269 B or 8-candle, of the well known Edison type. The current will be supplied by two L dynamos, which will be driven by two direct acting Brotherhood steam engines. The work is to be finished by the end of April next. Lieutenants and other unfortunates condemned to pass their nights and part of their days in what is known as the "Pandemonium" on board these troopers, which encounter such roasting temperatures as are peculiar to the Red Sea and thereabouts, will bless the names of Edison and Swan.

Insulating Wire.—A new method of insulating wire for electrical purposes has recently been adopted by the Triplex Insulated Wire and Rubber Company. The method consists in tinning the wire; it is then covered with a layer of soft rubber, around which a strip of soaked linen is wrapped, and which in turn is covered by an outer layer of thick, hard rubber. For underground wires another layer is added. The process of manufacture of this insulated wire is very simple, all the layers being put on in one operation by means of machinery, thus making it possible to furnish a comparatively cheap article. The wire is fed from a reel into a groove cut upon two steel rollers heated with steam, and simultaneously two strips of soft rubber, each more than covering one half of the wire. The excess of rubber is stripped. The coated wire is then automatically wrapped with soaked linen strips, and is carried to a second set of rolls, where two strips of hard rubber are united around it to a third coating.

Insulating Compounds.—Two patents have been taken out recently for insulating compounds. The first is numbered 3175, and was taken out, on the 5th July last, by Messrs. Bottomley, Barry, and Lundy. The inventors dissolve leather with dilute muriatic and chloride or sesquichloride of iron, or with caustic soda or other suitable solvents, which solvents may be expressed therefrom or neutralised therein as convenient. They also claim the use of animal, mineral, or vegetable pitch combined with raw or boiled linseed or other drying oil, and either with or without dissolved leather, osseine, glues, gutta percha or gum, as an insulating material. The second patent is numbered 3176, and was taken out by Mr. Mackay on the 5th July last. This invention consists in combining by heat at 100 to 212 deg. Fah. mineral wax, such as paraffin or ozokerit wax, vegetable tar (wood tar), shellac, and asbestos, in the proportions of—wax, 1; wood tar, 24; shellac, 32; asbestos, 32. The inventor also proposes to employ this composition for forming moulds for electro-plating purposes.

Electric Lighting in Bath.—A part of the spacious premises of the Merchants' Alliance Supply Stores in Stall-street, Bath, is now lighted by means of Brush lamps. The ground floor is all that is at present completed, and this is divided into three departments—the shop for general tailoring and hosiery, the second department for mechanics' clothing, and the third for boots. All these are lighted by the Brush system. There are altogether six arc lights, four inside and two outside the premises, one of the latter being placed on the top of the house and fitted with a "head light reflector" similar to the reflectors used on the front of the locomotives in the United States, and capable of throwing a ray of light for a half-mile. These lights are supplied by a No. 5A Brush arc light machine, driven by a six horse-power horizontal steam engine erected by Messrs. Adlam and Son, of Bristol. The lamps and machines have been erected by the Great Western Electric Light Company, under the superintendence of Mr. P. Jolin, their electrician.

Electric Lighting at Parkstone Station.—The railway station and hotel at Parkstone, near Harwich, belonging to the Great Eastern Railway Company, are to be lighted by incandescent lamps. The Swan United Electric Light Company will carry out the work. Two hundred and fifty Swan lamps of 20 candle-power are to be fitted up to begin with. The current will be supplied by 55 four horse-power Faure-Sellon-Volckmar accumulators, as made by the Electrical Power Storage Company. The fittings throughout are to be supplied by Messrs. Laing, White, and Wharton, of Holborn. Parkstone is a very important station, as all the Continental traffic of the Great Eastern Railway Company goes through it. No doubt the new lights will be much appreciated by travellers using the company's hotel, particularly if they happen to have had a rough sea voyage. The cool and fresh atmosphere afforded by the use of the electric light, as compared with the vitiated and burnt air which is peculiar to rooms in which gas been burnt, will, to passengers lately under the influence of *mal-de-mer*, have a particular charm.

The Telephone in Dundee.—The local authorities in Dundee are going in extensively for the telephone. The police commissioners have instructed the National Telephone

Digitized by Google

Company to run eighteen "private" wires from their central station, four to branch stations, one to the chief constable's house, one to the deputy chief constable's house, and one to the police surgeon's house. The other wires will run to the firemen's houses, gas commissioner's office, water manager's office, and other places. The same company are also about to erect private wires from the water manager's office to the two reservoir keepers' houses, and to the manager's private house. Another private wire is to run from the police clerk's office to the burgh engineer's office. The Board of Guardians are going to connect their workhouses and the parochial offices with the Company's Central Exchange in Panmure-street, and, finally, all the municipal offices are to be coupled up to the exchange. The work will be carried out under the superintendence of Mr. Frank Lumley, C.E., the company's electrician and manager.

Telephonic Repeaters.—Mr. T. D. Lockwood, well known in America as an authority on telephonic matters, writes as follows with reference to Mr. A. R. Bennett's telephonic repeaters, recently described and illustrated in our columns:—"As a matter of fact, there is very little new in this device. It was certainly used in the autumn of 1879 by Mr. Thomas A. Watson and myself, the object we had in view being the same as that of Mr. Bennett, viz., the communication of the articulating currents inductively from a metallic to an earth circuit, or *vice versâ*. The only reason we did not continue this, and introduce the plan universally, was that we found that on nearly all the lines the increased loudness attained on the direct circuit compensated so nearly the interfering noises that there was no sufficient advantage apparent in the use of the coils to warrant their introduction. To any thinking electrician who has examined the Blake transmitter, this plan of inductive repetition would be at once suggested, since in every such instrument it is used, the electrical undulations in the primary coil being caused to induce similar currents in the secondary."

The United Telephone Company.—The chairman of this Company has issued a circular to the shareholders, in which he summarises the recent legal proceedings which were taken to uphold the Company's patents. In referring to the last trial, viz., the appeal of Messrs. Harrison, Cox-Walker, and Co., against Mr. Justice Fry's decision of May last, he alludes to the possibility of an appeal to the House of Lords by the above-mentioned defendants, but expresses the confidence felt by the directors that even in that eventuality they will gain the day. The latter part of the circular contains some interesting statistics of the progress made by the Company. It states that, on the 28th February, 1881, the number of subscribers to the London Exchange was 845; on the same date of 1882, this number had increased to 1,505; and on the 28th February, 1883, to 2,541. As showing the use made of the Company's system, the circular further states that the total calls for the five days included between the 15th and 21st February, 1881, were 22,256, or a daily average of 4,451; in 1882, for the same period, they amounted to a total of 48,586, or a daily average of 9,717; and for the same period in 1883 the total was 95,108, giving a daily average of 19,021.

Magnetic Storms and Data.—We take the following from the report of the Kew Committee of the Royal Society for the year ending 31st October, 1882:—"Three magnetic storms, or periods of considerable disturbance of the needles, have been registered during the year; viz., on April 17th and 20th, and on October 2nd. All were accompanied by auroral displays, but these were only observed in this country on the latter date. The following is a summary of the number of magnetic observations made during the year:—Determinations of horizontal intensity, 33; dip, 138; absolute declination, 28. At the request of the Polar Committee of the Royal Society, a number of old magnetic instruments were removed out of store, and after repair, packed and delivered to Captain Dawson, R.A., who has been entrusted by the Government with the charge of a temporary observatory established in connection with the international system at Fort Rae, Great Slave Lake, N.W. America. Other instruments were lent to the Rev. S. J. Perry, F.R.S., for use during their residence in Madagascar for the observation of the transit of Venus by a party under his direction; and a third set were prepared for Dr. Ristori, who projected an expedition to Iceland, but has not yet started for that country."

Electricity; its Characteristics and Uses.—The second lecture under this title was delivered by Mr. J. H. A. Macdonald, Q.C., before the members of the Edinburgh Philosophical Institution on Friday week. Beginning by referring to the relation between magnetism and electricity, the lecturer explained and illustrated the different characteristics of magnets—some of these being that the power they possessed developed itself at the ends only, and in opposite degrees at each end; that magnets could be produced by electricity; and that in electrical magnets their power was displayed in certain regular lines of force. The principle upon which dynamo machines generated electricity was also explained, as was likewise the system of accumulating electrical energy by storage batteries after the Faure-Sellon-Volckmar method. Turning to the uses of electricity, the lecturer explained the telegraph, telephone, microphone, the various kinds of electric lamps, &c. This lecture, like the preceding one, was illustrated by numerous diagrams, apparatus, and experiments. The portion of it dealing with electric illumination was illustrated by a number of Lane-Fox incandescent lamps, supplied from 25 accumulators of the Faure-Sellon-Volckmar patent, made by the Electrical Power Storage Company, London. A 1,500 candle-power arc "Brush" lamp, fed by a dynamo placed in Messrs. Constable's printing establishment, near at hand, was suspended from the roof of the hall.

Electrolytic Estimation of Zinc.—An abstract of a paper by A. Millot, in the *Bull. Soc. Chim.*, Vol. 37, 2nd Series, pp. 339-41, was given in a recent number of the *Journal* of the Chemical Society. According to the author, the process is as follows:—"2·5 grams of the mineral are dissolved in 50 c.c. of hydrochloric acid, and a small quantity of potassium chlorate is added to the boiling solution in order to precipitate the iron. If the mineral contains much silica, it is previously evaporated to dryness with hydrochloric acid. The liquid is cooled, diluted, and mixed with 100 c.c. of ammonia, and 50 c.c. of a saturated solution of ammonium carbonate in order to precipitate the lead and calcium. The liquid is diluted to 500 c.c., filtered, and 100 c.c., corresponding to ·5 gram of the mineral, and containing from ·2 to ·3 gram of zinc, are mixed with 1 gram of pure potassium cyanide and placed in a beaker, in which is suspended a cylinder of platinum gauze, which acts as the positive pole, and a platinum cone like that in Riche's apparatus, which acts as a negative pole. Two Bunsen cells or a Clamond thermo-electric pile of 150 elements may be used to effect precipitation, which is complete in about ten hours. The firmly-adhering deposit is washed with water, then with

Digitized by Google

alcohol, and dried. If the mineral contains copper the latter is deposited with the zinc. The deposit on the cone must in this case be dissolved in nitric acid, and the copper precipitated from the acid solution. If cadmium is present it must be removed by treatment with hydrogen sulphide. The potassium cyanide should be used in the proportion given above. If more is added, the metal is deposited very slowly, whilst if less is added the deposit of zinc is not adherent. Any action on the electrodes may be prevented by mixing the solution with ammonium acetate or nitrate. The latter, however, retards the precipitation of the zinc."

Telegraph Clerks' Grievances.—A largely-attended meeting of telegraph clerks was held in the Glasgow Christian Institute on Saturday night last. After some discussion, the following resolution was proposed :—"That this meeting is deeply dissastisfied with the scheme of revision applied in 1881 to Her Majesty's Telegraph Department, and cannot regard as final any scheme which fails to satisfy the claims put forward in the petition of the postal telegraph clerks of the United Kingdom to the Postmaster-General in 1881." The resolution was seconded and carried unanimously. Another resolution was proposed and seconded, as follows :—"That this meeting calls upon the central committee of the Postal Telegraph Clerks' Association to use every legitimate means to obtain a concession of the claims put forward by the postal telegraph clerks of the United Kingdom in their petition of 1881." The resolution was adopted unanimously. It had been considered wise to give the scheme lately inaugurated a fair trial, but as it had been found in many details to fall short of what was deemed a fair and final settlement of the grievances complained of, the time had now come to renew the agitation and to use all legitimate means to obtain the claims formerly laid before the Postmaster-General. A resolution expressing gratification at Mr. Fawcett's recovery from his recent illness was afterwards passed, and the proceedings were brought to a close.—A meeting of telegraph clerks was held in Dublin on Saturday, at which resolutions were adopted expressing dissatisfaction with the late revision of salaries, and expressing conviction that no scheme could satisfy the service that was not based on the united petition of 1881, and asking for the appointment of a select committee to inquire into their grievances. A motion was adopted strongly condemning the action of the Glasgow authorities in suspending the local secretary for posting a notice convening a meeting of his fellow clerks, and sympathising with him.

The Elphinstone-Vincent Dynamo.—A series of experiments were made with the Elphinstone-Vincent dynamo, on the evening of Wednesday, February 21st, at Messrs. Unwin Brothers' printing office, the Gresham Press, Little Bridge-street, Ludgate-hill. A large warehouse on the first floor was fitted with 350 Swan incandescent lamps, each of 20 candle-power, suspended from the ceiling. Lord Elphinstone explained that the machine was capable of driving 416 Swan lamps, but owing to delay only 350 could be set up. Mr. Vincent briefly explained the construction of the machine, after which several experiments were shown, amongst others a length of about 40ft. of galvanised iron wire, $\frac{1}{8}$in. thick, was rendered red hot. As the heat increased the zinc burnt off in brilliant coruscations, the heat kept on increasing up to whiteness, and finally the wire fused, parts of it as it struck the floor breaking up into brilliant globules of melted wrought iron. Lengths of steel, and also copper wire, each became in turn incandescent, the steel being fused. The current was then made to run through a coil of iron wire immersed in a glass vessel holding three quarts of water. Instantly there was a hiss as when a red-hot poker is plunged into water. This was followed almost immediately by steam; in half a minute the water boiled, and before a minute had elapsed half the contents of the vessel was on the floor. An ordinary steel flat file, 1in. by $\frac{1}{4}$in., was then placed instead of one of the carbons in an arc light, and the current being passed through, the end of the file was melted and consumed like a tallow candle in a fire, throwing off a shower of sparks with a Catherine-wheel-like effect. The experiments concluded by the lighting up of a very powerful "Search Light," as used by the Navy, the carbons of which are $1\frac{1}{4}$in. in diameter, capable of giving a light equal to 100,000 candles. The whole of the mechanical arrangements were carried out by Mr. Arthur Rigg, engineer to Lord Elphinstone and Mr. Chas. W. Vincent, under the superintendence of Mr. S. G. Wilmott, his manager, who also assisted Mr. Vincent with the experiments. The motive power used for driving the dynamo machine was supplied by one of Rigg's patent high-speed engines, capable of developing 60 indicated horse-power. A description and illustration of the Elphinstone-Vincent dynamo appeared in our issue of Jan. 20.

Electric Lighting for Workshops.—In the course of a discussion on Mr. A. Jamieson's paper on electric lighting for workshops recently read before the Institution of Engineers and Shipbuilders in Scotland, some interesting statements were made by various gentlemen who had had practical experience of the working and cost of the electric light. Thus, Mr. A. C. Kirk, of the firm of R. Napier and Sons, stated that his firm had been one of the first in Glasgow to adopt the light. They were using Brush arc lamps in their yard and elsewhere, and were well pleased with them. As to the cost, he stated that he had "found that while burning the lamps three hours a day, the cost of each lamp per week was about 5s. 7d. That was counting twelve lights. He put down 1s. 6d. for the cost of maintenance, and the half of a man's wages for attendance—15s. per week; cost of carbons, 8s. 6d.; and after allowing for the depreciation of the Brush machine, the whole cost was £2 1s. 9d., or 3s. 7d. each for the twelve lamps per week. If the lamps were kept burning 49 hours a week, the cost per lamp would be about 6s. per week. In fact, the increased number of hours did not add very much to the cost, beyond the price of the carbons." Mr. Dick, of the Newton Steel Works, stated that they had been using 14 or 15 Brush lamps. "He had made up a rough estimate of the cost of lighting the works for the six months ending 31st May, 1881, and the six months ending 31st May, 1882. The first great falling off was in the quantity of naphtha used. The cost in 1881 was £172 1s. 6d., and in 1882 £102 8s. 10d. In 1881 the lamps used cost £15 4s. 11d., and in 1882 £2 5s. 6d. Altogether the saving for the six months was £89 3s. 5d. In the foundry alone there was a saving of £19 6s. 1d. Against the total saving there would have to be put £81 6s. for labour and upkeep. He had not been able to form an exact estimate as to the cost of the coal used, but thought that £8 would be pretty near the mark. Although the total saving was but £19 1s. 6d., there was a further profit in the superiority of the work turned out and the amount of it that the men could get through. The lamps were not quite so steady as could be desired, but this was probably owing to the dust that was flying about the works." Mr. Gilchrist (of Barclay, Curle and Co.) said his firm had used the electric light last winter, and through the extra illumination they got a great deal of extra work done by the men, and it was without doubt a capital light for factories, workshops, and large open spaces.

A GUIDE TO PRACTICE IN THE SUBMARINE CABLE TESTING ROOM.

No. XV.

In accordance with the plan marked out at the commencement of these papers, we have introduced to the learner's notice the operations which he would be expected to master as nearly as possible in the order in which he would meet with them in practice, and if he had intelligently gone through the course explained in the preceding numbers he would by this time be in a position to afford useful service in the testing room. With one exception only we have given sufficient instruction to insure his position up to a certain point, even if we extended it no further. This exception is important, and our plan would lack a necessary feature if we intended it to be permanent; we refer, of course, to the working out of the tests, reducing the observations to actual figures, and obtaining particular values for the indications otherwise merely general. In order to explain this part of the subject clearly and thoroughly we must consider the construction of the formulæ which govern the course of calculation; and it appeared safer to make this a separate branch or section than to interweave it between the different tests, a course invariably involving repetition; whilst there is another strong reason for so acting, viz., that in practice the learner will, in nine cases out of ten, acquire the ability to work out the tests mechanically. He will be shown how to add or subtract certain logarithmic numbers in different instances, and can be trusted to present correct results without really understanding the *rationale* of his work. We make these remarks lest we should appear to neglect a most important item in our programme. Before, however, entering on this subject, there are other forms of test for consideration which the learner ought to acquire. They are not so generally used in the testing room during manufacture as those already explained, but are most conveniently introduced at this point, as it will be seen later on that the day will come when one or all of them may be necessary, and no time or opportunity may be afforded for learning them properly. These tests relate severally to copper resistance (C.R.), inductive capacity (I.C.), and insulation resistance (I.R.), and will be considered in this order, as were those in the preceding numbers. We commence with the test for C.R., by "reproduced deflection." It is rarely necessary to employ this test where both ends of the cable are available, and as a rule it is used either during or after submergence. In this case one pole of the battery is to earth as well as the further end of the cable. When taken at the works it can be done in this way, or without using earth connection at all. Mr. Kempe in his work on "Testing" commences by introducing this kind of test, and remarks that, though very simple, it is inferior to no other in point of excellence of principle. This is true, and as the author shows through the whole chapter, it is very comprehensive and useful. But the employment or otherwise of this test depends on circumstances which are not detailed by him, and the conditions are not the same when it is used as there suggested, as they are when taken with a submarine cable. Moreover, without closer explanation than Mr. Kempe has given, a beginner would not succeed in getting any sufficient results, at any rate with the appliances which he finds in the testing room. However, Mr. Kempe does not say his remarks refer solely to submarine cables, nor does he specify the particular instruments to be employed. In considering this test as taken during manufacture we must necessarily omit certain features which are only present during the operation when performed on a submerged cable. These points will come before us at the proper time. The principle of the test is as follows:—We have an *unknown* resistance whose amount we desire to measure, and instead of directly balancing a *known* resistance against this, we measure first the unknown (or cable) resistance by passing a current through a galvanometer in circuit with it, and noting the deflection, and afterwards substitute a variable resistance in its place, and arrange this until the same deflection is reproduced. To avoid needless waste of time the amount of resistance introduced in the place of the cable is chosen as nearly as possible equal to that of the section to be tested, which must be guessed at or rather estimated by means which the learner now readily understands. We may compare this mode of finding the C.R. with the Wheatstone bridge test by referring to the operation of weighing some body or substance.

Achieving a balance with a pair of scales illustrates the latter, and supposing some disturbing influence to prevent our using them in another case, the former method may be paralleled by imagining we have an apparatus as a steelyard without the marks appropriate to the different weights, and, attaching first the body to be weighed, that we mark the place to which the index reaches by the pull on the spring, and then substitute different known weights till the index touched the same mark. The weight is then known to be that of the piece which produced this effect, just as the amount of resistance by which the former deflection was reproduced is the measure of the unknown or cable resistance first put in circuit. It is considered by authorities a superior mode of C.R. testing, partly for its simplicity; and, certainly, under those circumstances in which it is more generally employed, it affords results which it might be almost impossible to achieve with the Wheatstone bridge. As regards the connections for the test nothing can be more simple. The principle is the same as that of the insulation test already illustrated, but there is this difference with regard to the object of measurement—the resistance with which it is concerned is immensely small in the one case compared with that involved in the other, and the standards of comparison in the two cases are very different in their proportion to that which they determine. These points are important in connection with the arrangement of the galvanometer employed in the test now before us; and the fact that the correctness of the result depends partly on the sensitiveness of this instrument is an additional reason for commencing the operation by attending to this arrangement.

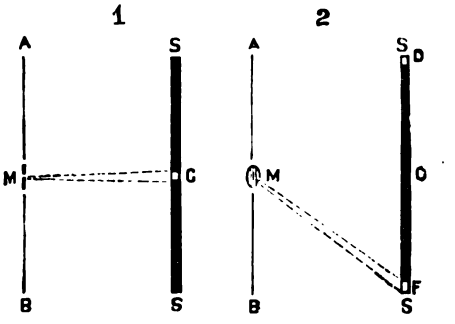

FIG. 33.

As the galvanometer is very sensitive, and the resistances to be measured are comparatively small, the current passing through them from a small number of cells will produce a considerable swing of the mirror, so that unless we had an immensely long scale we should have no readable deflection under the ordinary position of the mirror and magnet within the coil. The learner understands that their normal position, or that when no current is passing through the instrument, is in the same plane as that of the coil surrounding them; and that a line drawn, say, from the centre of the scale on which the spot is at this time reflected to the mirror strikes it at right angles to a line through the centre of the latter in the plane of its suspension (see Fig. 33). (We are supposing the centre of the scale to be practically at the same height above the table as the centre of the mirror. Speaking with absolute correctness, this would not be so, as the reflection on the mirror of the light must leave its surface to fall on the scale at an angle however small). But for our purpose we may assume that the line above mentioned is at right angles to the surface of the mirror when no current is passing, and, therefore, that if the mirror were deflected either way, *this line* would strike the plane of suspension obliquely (see Fig. 33). Any considerable deflection on either side would then throw the spot off the scale. Now, in tests for C. R. it is desirable to take

Digitized by Google

observations with both + and — currents; several of each kind are made, and the mean of these is the truest result. When taking the regular C. R. tests every day with the Wheatstone bridge this is not always done. But when operating with a submerged cable alternate currents are employed, and when testing by a reproduced deflection this object is carefully kept in view. Though we are not now concerned with the work of cable submergence, the test must be explained with as little omission as possible. The point to be aimed at is to arrange our appliances so as to have the zero in the centre of the scale, and that the deflections for either current may be within readable limits. It is evident that whatever length of cable we may have to test, if we allow the whole of the current to pass through the galvanometer coils we shall have too large a deflection; in other words, we are obliged to use a shunt, and one that will divert by far the greatest part of the current. We, therefore, introduce between the galvanometer terminals a short piece of wire, which, presenting a very small resistance, shall yet not actually short-circuit the former. We must leave it sufficient sensitiveness to show some small proportion of resistance. In Fig. 34 we have shown the connections arranged in the simplest manner for the most convenient performance of the operation. But if without further preparation a current were sent through the circuit (the cable being joined up with the galvanometer) a deflection would still not be readable, but would be off the scale. Therefore, before bringing the cable into circuit, we should join up as much resistance as will equal the estimated resistance of the former (always

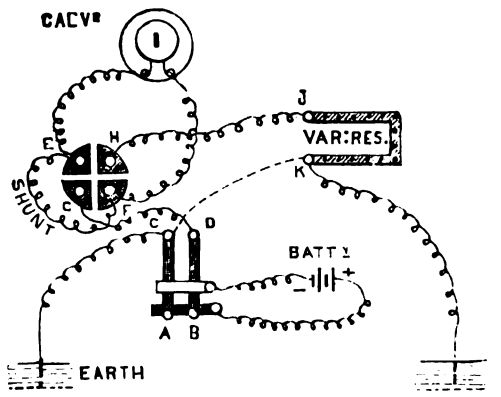

Fig. 34.

approximately known), and depressing the battery key (Fig. 34) the spot will pass off the scale; but by now turning the large directing magnet slowly round the light will be brought back to zero (at the centre), when it must be turned no further. The mirror magnet has been acted on in a direction contrary to that of the current's influence. When this point has been gained, the battery key is released, and the resistance box being disconnected, the cable is put in its place, Fig. 35. A commutator is necessary for conveniently taking this test, and we have suggested the plug arrangement as most suitable, though any reversing key would answer. Its usefulness will be at once apparent on considering that it is desirable to have the deflections for opposite currents on the same side of zero, that is, always in the same direction. We have mentioned this feature in a former number, but may allude to it at this point, as there is additional reason here for reminding the reader of the conditions governing the arrangement of the galvanometer. The thread suspending the mirror is supposed to allow of no torsion or twisting of the fibre, so that theoretically it may hang in any position, and the effect of a current in any direction is equal, or, as it may be put, an equal deflection to the right or left represents truly an equal influence in either direction on the little magnet. But it is safer to allow the opposite currents to act on the mirror in the same direction, and, when reversing the battery, to reverse also the plugs in the commutator, and read off the deflections on one side only of zero. Proceeding with the test, which we can take either with or without earth connections, according to circumstances, there is no doubt that when both ends of the cable are available it is preferable to join them up in a complete metallic circuit. Indeed, the only difficulty arising in the course of the operation is caused by what are called "earth currents," from which the cable is protected if there is no conductive communication with earth. But, as the test is more particularly employed for submerged cables when these connections are indispensable, we prefer to illustrate it in this way. The cable being joined up, we will commence by depressing the right hand key, thus sending a positive current into the circuit. We are to use alternate currents, and, although when the test is taken at the works it does not much matter which current is first applied, yet as the choice of currents to commence with is a point of some importance under other circumstances, we shall imitate it here, explaining the matter later on in its appropriate place. After removing the short-circuit plug, the effect of putting on the current is to cause a deflection on the scale which will be larger or smaller according to circumstances. It must be remembered that, since the directing magnet has been turned so as to deflect the mirror considerably from its original position at zero, when no current is passing in the circuit the spot will be invisible, that is, off the scale. It was only brought to zero after first charging through the circuit made up of the estimated resistance and the galvanometer coils. Therefore, when the cable or resistance is joined up, there is no spot visible until the battery is put on and the short-circuit plug is removed. In saying, then, that the deflection is larger or smaller, we speak of it as starting from zero, and any number of divisions for its value means counting from this point. If when the zero was

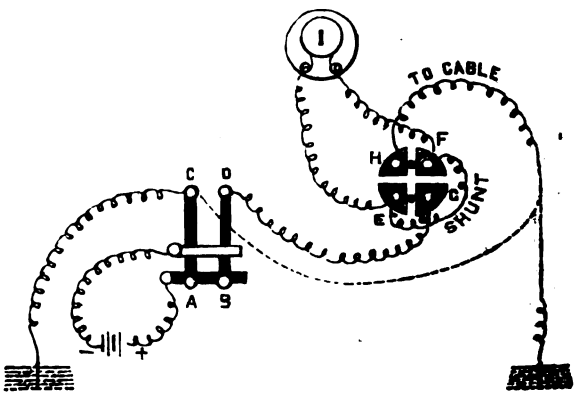

Fig. 35.

arranged the estimated resistance had been exactly equal to that of the cable, there could be no deflection at all beyond zero; but this never happens, or, at least, unless there be disturbing influences, and the resistance of the cable be varying during the test. If there be no such disturbance as arises from earth currents, and particularly if the circuit be metallic throughout (without earth connections) the deflection will be quite steady. When we go over this test at a shore station during the laying of a cable, we shall see that this is not so. Let us now suppose we have a deflection of 100 divisions, say, to the right of zero. The short circuit plug is now replaced, and the commutator and battery are both reversed. The plug between H and E will be removed to the hole between E and G, and the key B released while A is depressed, when a negative current will pass through the circuit; and on removing the plug, which is now the short circuit plug, a deflection is seen in the same direction as the first, say, 98 divisions. The positions of the key and plugs are shown in Fig. 35. By tracing the course in each case it is seen that the positive current entering through E at the terminal of the galvanometer coil has the same effect on the mirror as the negative current which passes in the opposite direction. If both had gone the same way round, the deflections would have been opposite the one to the other. The process is generally repeated several times, using alternate currents and noting the several deflections. The cable will now be disconnected, and the resistance box joined up in its place, the same amount of resistance being unplugged as before, and the deflections just given by the cable are to be repro-

Digitized by Google

duced; or, at least, the last two of each pair if there were several taken. We commence with the negative deflection merely because the commutator plugs are in the right position (as we just now left them), and we had 98 divisions with this current. The battery key A is depressed and the short circuit plug removed; the spot should appear at zero as the original resistance is in circuit. It is required to bring it to 98 on the right hand. The question arises, Shall we unplug more resistance, so increasing the amount in circuit, or plug in so as to reduce it? This depends on the position of the plugs in the commutator when the zero was fixed by inserting the estimated resistance at the beginning of the operation, and also on the current, whether + or −, employed for that purpose. If a + current was used, and, the plugs being horizontal as in Fig. 35, if the spot was sent off scale to the right-hand, it showed that additional resistance in the circuit caused a right-hand deflection *under those circumstances*. Consequently, when with a negative current we desire to deflect the spot to 98 on the right, the plugs must not be in the horizontal position, and the resistance of the circuit must be increased. We therefore employ more resistance until we have the spot at 98. When we reverse the current, and desire to reproduce the positive deflection 100, we must still unplug more resistance, but the commutator plugs must be in the vertical position, as in Fig. 34. In the present instance there is but little resistance to be added. If we had commenced by reproducing the larger deflection, we should have to reduce the resistance when we came to reproduce the smaller value (98), and therefore to plug in the resistance-box which had too great an amount in circuit (that for 100).

If several tests with both currents have been taken, the deflections of each current are reproduced separately; that is, all the + consecutively, and the same with the −. When testing a submerged cable the resistances obtained are all more or less different. It is then customary to take a mean value for each pair of resistances of opposite currents as affording the most correct results. We shall partly explain the working out of the test at this point instead of postponing it as we have done with other tests, without, however, going exhaustively into it. Indeed, the formula once given, there is but little work to do. In this case the object is to find what is called the harmonic mean of each pair of resistances, this being the recognised C.R. of the section under test.

The learner is presumed to know that the mean of any two values or quantities in a progressive series signifies generally the average, and that, unless otherwise specified, the arithmetical mean is intended, so that, if our two resistances were 98 and 100, the arithmetical mean would be 99, or $\frac{1}{2}$ the sum of the two numbers. If there were three numbers the mean would be $\frac{1}{3}$ the sum of the three, and so on. But there is a reason for considering the true mean of two such values as these C.R.'s taken with opposite currents to be slightly different from this. We say "slightly," because the difference in question is very small for certain quantities, and in cases where the values nearly approach each other as 98 and 100. The mean called harmonic derives its name from a law governing the vibration of rods or strings under friction, and is applied in the case of electrical resistance for reasons which we cannot discuss at present. The principle is, briefly, that in comparing or taking the average value of two copper resistances taken as we have stated, that is, with alternate currents, it is not truly found as a mean or term in an arithmetical series, but as a term of a series in harmonical progression. Calculated on this ground, the mean is found by the formula stating it to be twice the product of the two resistances divided by the sum. Thus, instead of being 99 as found by the arithmetical mean we have $\frac{2 \times 98 \times 100}{98 + 100}$, which $= \frac{19{,}600}{198}$, equalling 98·98 (recurring). This difference is very small, but it could easily be seen that with resistances, differing from each other in wider proportion there could be a much greater percentage of difference between their arithmetical and harmonic means. The learner must consult his algebra for the construction of the formula if he is not familiar with the rules. At a later stage we shall consider fully the application of the theory.

THE EFFECTS OF TEMPERATURE ON THE ELECTROMOTIVE FORCE AND RESISTANCE OF BATTERIES.*a*

BY WILLIAM HENRY PREECE, F.R.S.

It is well known that heat influences the conditions of galvanic elements so as to vary the strength of the current generated by them in those parts of the circuits connecting their poles.

In 1840 De la Rive* found that the action of a galvanic pair was accelerated when it was put into hot fluid instead of cold fluid, and he attributed the result to increased chemical affinity.

Faraday† repeated De la Rive's experiment, but he, on the other hand, attributed the result to improved conductivity in the liquid, and he showed that the effect was not due either to motion, to chemical action, or to thermo-electric action, or indeed to any increase in the electromotive force.

Daniell,‡ also, found an increased current due to increased temperature. According to him one of his elements was nearly trebled in strength when raised to 212° F. He attributed the effect to the increased energy of the affinity. Said he, "Changes of temperature even have a marked influence upon the working of the voltaic battery, and must not be neglected in nice comparative experiments."

J. B. Cooke§ made careful observations on the chemical affinity in a galvanic cell, and indicated the error due to changes of temperature, but he remarked, "These affinities do not appear to be affected by any changes of temperature between the ranges of 50deg. and 212deg. F."

Crova investigated the effects of heat on the electromotive force alone, and he showed (1) that the electromotive force of a Daniell element decreases regularly with an increase of temperature; (2) that the electromotive force of a Grove element increases with temperature; (3) that the electromotive force of a single-fluid element of the Smee type is independent of the variation of temperature.

In 1862 Mr. James Dixon took advantage of the influence of heat to take out a patent for hot batteries, and he suggested the employment of these batteries for the production of the electric light.

In the same year (1862) Lindig|| indicated a variation with changes of temperature.

In 1870 Bleekrode¶ made some further experiments in the same direction.

In 1872 Mr. Latimer Clark** showed that the electromotive force of his standard cell varied inversely with temperature about ·06 per cent. for each degree Centigrade.

In 1881 Herwig†† investigated the subject carefully, and showed that polarisation diminishes with temperature. He found that resistance decreased markedly with temperature, and that this was more evident with small electromotive forces than with powerful electromotive forces.

In 1878 the author‡‡ in investigating the peculiar action of Byrne's pneumatic battery showed that its exceptional power was due to an abnormal formation of heat in its interior, and that this acted, principally, in reducing the internal resistance.

As bearing indirectly also upon this question it should be noted that Becquerel, Paalzow, and Kohlrausch and Nippoldt examined the influence of heat upon the resistance of electrolytes, and showed that it invariably diminished as the temperature rose. This was determined by them for various solutions.

Now it is to observed that in all these inquiries no one has quantitatively separated the influence of temperature upon electromotive force from its influence upon internal resistance. It is quite evident, from an examination of Ohm's law, that the variation in the strength of current can be the result either of a variation in the electromotive force alone or in a variation of the resistance alone, or in an unequal variation of both together. The numerous discrepancies that have been made in the measurements of the behaviour of the Daniell cell, as well as the erratic performance of batteries used for telegraphic purposes in various exposed positions, have long attracted the attention of the author to the necessity of a more careful inquiry into this matter than has been made hitherto. In fact, all the observations that have hitherto been made are positively useless, from the simple fact that no record has been kept of the independent variations of the internal resistance and the electromotive force in any measurable or comparable manner.

Special apparatus was made, and the following method of experimenting was decided upon.

The cell to be experimented upon was placed inside a cylindrical copper vessel about 10 inches high and about 8 inches diameter; water was poured into the vessel to within an inch of the top of the cell, and the lid of the vessel was put on.

This lid had four holes, two (insulated from the rest of the vessel) to receive the electrodes of the cell, and the other two to allow thermometers to be plunged into the liquid or liquids in the cell without removing the cover or lid. The water in the vessel and the cell in the water were then heated by means of a gas-burner placed underneath the vessel, and the electromotive force and the resistance of the cell were determined at various stages of the heating; while the temperature of the cell was observed at the time of each experiment, the liquid or liquids in the cell were stirred up from time to time, so as to obtain, as far as possible, the true temperature of the cell.

The cells experimented upon were the Daniell, bichromate, and Leclanché; those in general use, especially for telegraph purposes.

The results of the experiments are given in the tables below, in which the electromotive force (e) is given in terms of that of a Daniell cell (a standard cell) in good order and at about 14deg. C., and the resistance is given in B.A. units. The experiments were conducted for me by Mr. R. Shida with great care and patience. Of the Tables I., II., and III., which contain the results of the experiments on the Daniell cell, the first two tables refer to the case where the solution of copper sulphate was saturated at all temperatures (that is to say, the crystals of copper sulphate were always present in the solution) and the solution of zinc sulphate was kept the same, or nearly the same, in strength (that is, the solution was saturated at about 14deg. C.). Table III. refers to the case where both copper sulphate and zinc sulphate solutions were kept unaltered or nearly so in strength during the experiment (that is to say, they were both saturated at about 10deg. C.). Table IV. contains the results

for the double-fluid bichromate; Table V. those for the single-fluid bichromate; and Table VI. those for the Leclanché.

(1.) As regards the electromotive force. *(a.) The Daniell Cell.* Tables I., II., and III. show that, as the cell was heated up from a comparatively low temperature to a higher and higher temperature, the electromotive force of the Daniell cell decreased rather abruptly at first, but more gradually afterwards, until, at a certain temperature it began to increase and continued to do so till the temperature attained that of the boiling point of water; but that (which is rather singular) the electromotive force remained unaltered, or nearly so, while the cell was being cooled down from 100deg. C. to a lower and lower temperature. These peculiar results (together with the fact that whereas the temperature of the zinc cell rose faster than that of the copper cell while being heated up, the former cooled faster than the latter while cooling down from a high temperature—say 100deg.C.) tend to indicate that the diminution in the electromotive force of the cell at the beginning of the experiment was greatly, if not chiefly, due to the thermo-electric action which must have been set up in the circuit.

(b.) The Bichromate Cell.—It will be seen from the Tables IV. and V. that the electromotive force of the bichromate (both the double-fluid and the single-fluid cell) diminished regularly when the temperature was made higher and higher, and increased regularly when the temperature was made lower and lower. The regular diminution by rise and regular augmentation by fall of temperature of the electromotive force (at least when the range of temperature was between 0deg. C. and 100deg. C.), was very much greater in the case of the single-fluid bichromate than in the case of the double-fluid bichromate. In the case of the first, the electromotive force at 100deg. C. was as much as about 6 per cent. lower than that at about 14deg. C.; whereas, in the case of the second the electromotive force at 100deg. C. was only about 1·6 per cent. lower than at 19deg. C.

(c.) The Table VI. shows that the electromotive force of the Leclanché varied when the temperature was varied so slightly, if at all, that it was difficult to observe the variation by the method used.

(2.) *The Internal Resistance.*—The results obtained for the resistances of the various kinds of cells are more striking and more interesting than those for the electromotive force, as will be quite evident from the tables. They will, however, be understood more readily from the graphical representations of the results by means of curves (in the Diagrams I., II., and III.), in which the abscissæ are proportional to the resistances in B.A. units, and the ordinates to the temperatures in degrees Centigrade.

(a.) The Daniell Cell.—The curves in the diagram I represent the results for the Daniell, the curve ABCDE corresponding to the case (Table II.) in which the copper sulphate solution was kept saturated at all temperatures, while the zinc sulphate solution was kept constant in strength, and the curve *abcde* corresponding to the case (Table III.) in which both solutions were kept unaltered in strength during the experiments. The directions of the arrows indicated the order of the experiments. For instance, in the curve ABCDE the portion AB represents the result obtained while the cell was being heated up from about 11deg. to C. nearly the boiling point of water, the portion BC that obtained while the cell thus heated up was being cooled down from 100deg. C. to about 12deg. C.; and, lastly, the portion DE that obtained in cooling the cell from 12deg. C. to nearly so low a temperature as the freezing point of water. A very similar explanation applies to the curve *abcde*.

The results thus laid down by means of the curves ABCDE and *abcde* present many points of interest. These curves clearly show:—

1°. That when a Daniell cell is heated from a low temperature, say 0deg. C., up to a high temperature, say 100deg. C., the resistance of the cell decreases rather abruptly at first, but more gradually afterwards, falling from 2·12 to ·66 ohms, or more than one-third.

2°. That when the cell thus heated up is cooled down, the resistance increases, but increases in a greater rate than it decreased while being heated; in other words, the resistance of a Daniell cell at any temperature (at least between 0deg. C. and 100deg. C.) is smaller before it is heated up to a high temperature than afterwards, provided the heating and cooling be done not very slowly.

3°. That if the cell thus cooled down be left undisturbed at a certain temperature, the resistance of the cell gets less and less, till at last, at the end of a certain period (which will be from about 40 to 50 hours), it gets down to the value which it had before being heated up at all.

4°. And, lastly, that the resistance of a Daniell cell is considerably less when the solution of the copper sulphate is more concentrated than when it is less concentrated, at any temperature, and under otherwise exactly similar circumstances.

(b.) The Bichromate Cell.—The results for the bichromate are not quite so remarkable, nor are they so interesting as those for the Daniell cell, as will be seen on comparing the curves in the Diagram I. with those in the Diagram II.; but the fall of resistance is, nevertheless, very striking. In the case of the double-fluid bichromate, the curve HK of resistance obtained while the cell was being heated up, differs so slightly from the curve KN obtained while it was being cooled down, that the one is hardly distinguishable from the other. The differences in fact may be attributed more to errors of observation than to anything else. Yet, if there should be any difference in the resistance in

Digitized by Google

the two cases, it is one opposite in character to that found in the case of the Daniell cell.

The probability of the existence of this difference, as indicated by the curve HKL, is supported by the results shown by means of the curve *hlk* for the single-fluid bichromate cell. Every point of the portion *hk* of the curve obtained while heating the cell up, lies considerably higher than the corresponding point in the portion *kl* obtained while cooling it down; that is to say, the resistance of the single-fluid bichromate cell at any temperature is greater before than after it has been heated up.

(*c.*) Very little remains to be said of the curve PQR in the Diagram III., which represents the results for the Leclanché cell. The general character of the curve PQR bears a strong resemblance to the curve HKL; in other words, the resistance of the Leclanché diminishes with the rise, and increases with the fall of temperature in nearly the same rate as the resistance of the double-fluid bichromate cell does. And, morever, it is a matter of difficuly to say with certainty, in the case of the Leclanché as in the case of the double-fluid bichromate, whether or not the curve of resistance obtained while being heated up coincides with the curve of resistance obtained while being cooled down, because the part RQ is so nearly coincident with the part PQ of the curve PQR, that any slight errors in the observations may have caused the non-coincidence between the two parts.

* Heating commenced. † Heating stopped. ‡ Experiments stopped and everthing left undisturbed till December 16th. Process of cooling by ice commenced.

It follows from these experiments that changes of temperature do not practically affect electromotive forces, but that they materially affect the internal resistances of cells. Faraday's observation is fully confirmed, while Daniell's mistake is easily understood if he employed, as he probably did, a galvanometer of low resistance.

It also follows that of the various forms of batteries in practical use the Daniell is most seriously influenced by variations in temperature, and that in all experiments with that battery either the temperature must be kept constant or frequent measurements should be taken of its internal resistance, and allowance made for the variation.

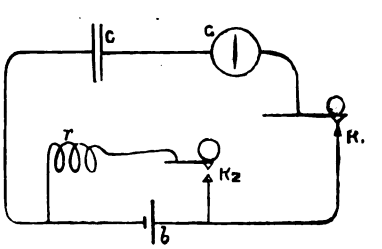
The method adopted to measure the electromotive force and the resistance of the different cells was very simple, and as it is believed to be very accurate and free from any of the disturbing



influences due to polarisation, a description of it may be useful. The charge or discharge of a small condenser through a galvanometer of comparatively low resistance is an accurate measure of the electromotive force present, for the duration of the current is extremely short, and, therefore, the whole quantity present acts as a balista upon the needle. C is a condenser of ·3 microfarad capacity, G a sensitive reflecting galvanometer, *b* the cell to be measured, *r* a shunt of small resistance, and K, and K_2 simple keys. The condenser is first charged with

Digitized by Google

a standard Daniell cell, and the charge deflection (D) noted. The standard cell is then replaced by the cell b to be examined, and the charge deflection (d) produced by it noted. The key K_2 is then depressed while K_1 is held down, and the cell is thus shunted through r. The electromotive force affecting the condenser is thus reduced, and a discharge (d') is noted—the deflection being in the reverse direction to d. Now, if E and e are the E.M.F.'s of the standard cell and cell b respectively, and b be the resistance of the cell under test, then

$$b = r\frac{d'}{d - d'}.$$

This particular mode of measuring was devised by Mr. H. R. Kempe, and modified by Mr. Munro, but condensers are much used in telegraphy for measuring electromotive forces.

ELECTRIC LIGHTING.

The Board of Trade has issued draft clauses such as are intended to be inserted in Provisional Orders, and with the draft clauses is the following memorandum :—

The following clauses are submitted for consideration as rough drafts of model clauses which are proposed to be inserted in Provisional Orders, and, so far as applicable, in licenses granted under the Electric Lighting Act, subject to such modifications as local circumstances may in any case render expedient.

They do not, of course, constitute a complete Order. Clauses applicable only in particular cases, clauses with regard to the breaking up of private streets, railways, tramways, &c., general clauses as to notices, &c., saving clauses, and others are omitted, but they are intended to include the main subjects of general interest as to which any controversy is likely to arise.

The following points require special attention :—

1. *The Choice of the Area of Supply.*

The clauses with regard to this are framed on the supposition that a fair area should be included in Schedule A, in which the undertakers may make an experiment, and to which, if they find that experiment not sufficiently remunerative to induce them to extend their operations, they may be allowed to confine themselves. At the same time, it is proposed that a further area should be included in Schedule B, to which the undertakers may, after feeling their way by their first experiment, extend their operations by degrees, subject to the right of the local authority, or where the local authority are themselves the undertakers, of certain inhabitants, at any time to require the undertakers to forthwith extend their operations over any part of such area or to resign their rights over such part. It is, therefore, suggested that local authorities in whose districts companies are seeking powers would do well to take care that the area proposed to be included in Schedules A and B respectively, are such as may fairly be included therein, having regard to the future development of the supply of electricity within the district. If, owing to local circumstances, as, for instance, in the case of small towns, they deem it necessary to allow the undertakers to include in Schedule A all the most remunerative part of the district, it will be for them to consider whether they should not propose clauses for withdrawing some part of the area included in Schedule A from the area of supply if the undertakers decline to extend their operations beyond it in order to encourage other undertakers to come in and supply a larger area.

2. *The Question of Capital.*

The clauses on this subject are only applicable in the case of companies. In such a case it is proposed that the undertakers should be required within six months to set aside and appropriate as a separate capital, for the purposes of the particular undertaking, such a sum as would appear reasonably sufficient to enable them to meet all probable demand for a supply in the area included in Schedule A; and, in addition to this, and as a part of such separate capital, to deposit or secure to the satisfaction of the Board of Trade within the same period a sum not less than one-half the amount, which may be reasonably calculated as the capital necessary to enable them to execute the works which they are required to execute within two years in certain specified streets in Schedule A., and to supply electricity therein. Similarly, in the case of Schedule B., additional sums are from time to time to be added to the separate capital of the undertaking, and fresh sums to be deposited or secured in respect thereof as separate parts of the area included in Schedule B are added to the area of supply to such amounts respectively as the Board of Trade upon directing such additions to be made may prescribe.

3. *As to the Modes of Supply.*

The parallel system is the system of supply adopted as the standard system in these clauses, and it is not proposed at first to give a right either to the local authority or to private consumers to demand a supply for public or private lighting on any other system; the provision is made that with the approval of the Board of Trade any other system may be substituted. Of course, by agreement any system whatever may be employed, provided that it complies with the regulations as to safety and otherwise, special provision being made in the clauses that if it is desired to supply at high tension for arc lighting or other purposes this may be done under special regulations.

4. *As to Time of Supply.*

It is proposed that this should be continuous, subject to six months' grace upon first commencing supply, when the undertakers need only supply between sunset and sunrise, and to a power on the part of the Board of Trade to permit special intermissions for the purposes of testing or otherwise. It may, however, be well for local authorities to consider in every case how far continuous supply is desirable for their district; as, however necessary it may be thought in crowded cities, where artificial light may probably be in constant demand, where there is only a slight demand in the daytime, as in country towns, the small additional convenience may not improbably be more than counterbalanced by the much higher price which must almost of necessity be charged for electricity where there is a continuous instead of an intermittent supply.

5. *As to Price.*

It is proposed that electricity should in all cases be charged for by meter; but as at present it seems doubtful whether there is any reliable meter for quantity or energy, a power is given to the undertakers to charge for the present, and until the Board of Trade otherwise direct, by the maximum current required, and the number of hours during which electricity is used. The latter, however, does not seem a very satisfactory mode of charging, and it is hoped it may soon be dispensed with, as there seems to be no doubt that meters for quantity and energy will soon be perfected for practical use.

6. *As to Limitation of Profits, Revision of Prices, Monopoly, &c.*

No clauses are inserted dealing with the above subjects. In the case of companies the undertaking can be purchased by the local authority at farthest at the end of twenty-one years at the then value of the plant. In the meantime there is, in the first place, the competition with gas, which is likely to be very severe; and, in the second place, the potential competition with other undertakers to keep down prices, as the Board of Trade see no reason whatever why such last-mentioned competition should not be an active and potent force. The accounts of the undertakers are open to all. No monopoly is, under the Act or the Provisional Order, granted or intended to be granted to them; and should they neglect their duties in the district, or charge exorbitant prices, there is nothing to prevent the immediate grant of a license or Provisional Order to a competing set of undertakers within the same district. In the case of local authorities there will be not only competition to look to, but also public opinion, and the Board of Trade prefer to rely upon the above considerations rather than to attempt to impose artificial restrictions, which, in other cases, have not proved too successful.

N.B.—*Any person desirous of offering any criticisms or suggestions with regard to these clauses is requested to do so by letter, addressed to the Board of Trade, and marked on the outside of the cover enclosing it "Electric Lighting Act," on or before the 14th day of March next.*

Board of Trade, T. H. FARRER.
26th February, 1883.

THE MEASUREMENT OF ELECTRICITY FOR COMMERCIAL PURPOSES.

The paper of Mr. Shoolbred read at the last meeting of the Society of Telegraph Engineers is an interesting *resumé* of existing information relating to special forms of apparatus for certain electrical measurements. The present is a kind of transition period, so far as the measurement of electrical quantities is concerned. In the application of electricity to telegraphy the quantities to be measured have been wondrously small, and the majority of existing instruments were designed with a view to the measurement of these small quantites. The introduction of the electric light upon a practical scale involved its establishment upon broad, but in many respects well defined commercial principles. The introduction of electrical transmission of power involves commercial principles similar to those applicable to the electric light. In telegraphic matters the producer and the user of electricity is generally one and the same person, but the same does not hold in the case of the general introduction of the electric light, nor will it hold in the electrical transmission of power. The producer and the user will be different persons, and hence the user will require some means of ascertaining the quantities he uses. A suggestion has been recently made that householders should be charged for light somewhat on the same principle as they are charged for water—by the size and rent of the house. We do not, however, consider such a system practicable. It is well known that in the case of water many users prefer to be charged by measurement and not by rule of thumb. We shall not discuss this suggestion further, but assume at once that in some shape or other the supply of electricity must be measured. The general public ask, Can such measurements be made? The scientific world answer they can, and already several inventors have devised apparatus for such work. The general tendency is to devise some apparatus that will do for electricity what the meter does for gas, and an automatic register will show the consumer the exact state of affairs from day to day. A knowledge of the laws which govern electricity is known to a comparatively small number of engineers, and those outside the select circle are somewhat incredulous as to what can be done. The President of the Society of Engineers, in his recent inaugural address, hinted at the doubts which are abroad. He said:—"Of course there are meters which register the current passing at any moment; but when it comes to the question of registering the amount of electricity which has passed through a wire during a given period, it is questionable whether it can be done in a reliable manner, inasmuch as the electrical energy is partially exhausted in the process of registration." We confess this sentence has led us to touch upon the subject now, for Mr. Shoolbred's paper clearly explains itself. It gives definitions and it describes apparatus, but we fear does not enlighten men who hold similar views to those just quoted. It is not proposed to send the working current of electricity through the meter, and, therefore, its electrical energy will not be partially exhausted. At present most of the proposed methods of measurement bear some analogy to the measurement of water passing through a large pipe by means of measurements taken of water passing, under similar conditions of head, &c., through a much smaller pipe. For example, suppose we have a mass of water, the head of water being constant. The water to perform work is taken through a pipe of area x, while the water actually measured in gallons or tons passes through a parallel pipe of area $\frac{1}{1,000}x$, or $\frac{1}{10,000}x$. Surely we can get an approximately correct idea of the quantity passing through the larger pipe in a given time. The electrical case is, however, simpler than that of the water. A definite but comparatively small portion of the total current will be taken through a branch wire, and this small quantity measured

Digitized by Google

just as if $\frac{1}{10,000}$th part of the gas was used to actuate a measuring instrument. So long as the proportion 1 to 10,000 was absolutely correct, so long would the user be able to tell at a glance at his register the quantity used, and we think we may safely state that the science of electricity is sufficiently advanced to enable us to give exactly the proportion of current used to actuate the register to that used in the working circuit. A definite quantity of electricity will perform a definite amount of work, and inventors like Sprague and Edison, knowing this fact, propose to use a certain proportion of the total current in doing such work as depositing a metal electrolytically. If a meter constructed upon this principle is placed in a house in connection with the electric light, $\frac{1}{10,000}$th, say, of the current coming to the house is used in the register, the other 9,999 parts are used by the householder. Hypercriticism from lovers of gas says some one has to pay for the quantity so used. This is admitted, with the addition that the quantity lost in this way will be so small as to have no appreciable effect upon the price. The proportion lost may be only one in a million, and we are quite sure one foot of gas lost in one million consumed would make no difference to the cost of gas. We have attempted to throw a little light upon this subject for the benefit of those who are not electricians, but who are taking considerable interest in the recent developments of electricity.

CORRESPONDENCE.

THE INVENTOR OF THE TELEPHONE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is impossible to let your article on the telephone appeal case pass without comment, and inasmuch as at least one of those who might protest is passed beyond the grave I venture to speak in his behalf.

The writer of the article says:—"It is by no means certain that the other investigators (including Reis) were even aiming at the result he (Graham Bell) aimed at—telegraphic signalling being far away different from vocal signalling." On the contrary, it is absolutely certain not only that Reis aimed at vocal signalling, but that he did not aim at multiple acoustic telegraphy. Reis himself in 1861 (*vide Journal* of the Physical Society of Frankfort, where Reis's paper "On Telephony by the Galvanic Current" appears in full) constructed his instrument—a combination of a tympanum with an electric current regulator—for the purpose of transmitting all tones that a human ear can hear, and chose the human ear with its tympanum as his model, *because* the human ear is, as he tells us, the organ which can take in the resultant effect of all the complicated vibrations produced by the organs of *speech*. That he aimed directly at this result is absolutely clear. That he attained at that time to a certain degree of success is equally clear, for he discusses the reasons why he did not get all the vowel sounds with equal distinctness. A year later, with perfect instruments, still based on the type of the human ear, he succeeded in transmitting speech so well that the varied inflexions of the voice in surprise, interrogation, command, &c., could be recognised. He himself gave to his instrument the name of "The Telephone," a name which the later patentees of improvements have still retained. Far be it from me to discredit the merit of their improvements; but since both Graham Bell and Edison have in their own published writings recognised the claims of Reis by quoting the very documents in which Reis's claim to invent "The Telephone" had been set forth in 1861-2, and in which that which I have stated above about the intent and extent of the invention is to be found, I, who go back to the documents to which both Bell and Edison refer me, and find there Reis's own invention set forth and claimed as his, am bound to accept the reference, and to believe that Reis did invent what he says he intended to invent, namely, an instrument which should transmit to a distance, by the agency of an electric current, "the total actions of *all the organs operating in human speech*."

What are the facts? A man in 1861-2 invents an instrument and tells you what it is for. He tells you you have to talk or sing into one end of it, and that speech or song, as the case may be, will be transmitted to the other end. We try it, and we find that we can make it work and speak uncommonly well. Surely this is the very essence of invention, and yet, in 1883, the writer of an article in *The Electrician* can be found who will say that it is by no means certain that Reis "was even aiming at the result" which Graham Bell aimed at!

The writer of this same article—the accuracy of which may be pretty well judged of by the foregoing sample—proceeds to say that Reis's instrument "in the hands of experts can now be made to speak *like a telephone*, or, at all events, some people are obliging enough to fancy that it can." This is magnificent. We shall, perhaps, be told next that a Duboscq lamp can in the hands of experts be made to shine like an electric light, or that, at all events, some people are obliging enough to fancy that it can. But the writer has surpassed himself when he proceeds:—"In the hands of Reis it could not articulate, and on the principle of construction adopted by him it never would have articulated, except by accident." Very cleverly put, perhaps, but, unfortunately, untrue. But mark what follows:—"That accident did not occur, or, *if it did*, it threw no light on the cause of its occurrence!" Let us proceed with our paraphrase, and see how it would look if we were to be told "In the hands of Duboscq the lamp would not give light, and on the principle of construction adopted by him it never could have emitted light except by accident. That accident did not occur, or, if it did, it threw no light on the cause of its occurrence or on the true conditions of success in electric lighting." Yet there is just as much evidence that Reis intended his telephone to transmit speech as that Duboscq intended his lamp to emit electric light. Neither was perfect. But each attained its own measure of success, and each was a meritorious invention.

One word more on the principle of construction—it was twofold. In the transmitter the essential feature was the combination of a tympanum (to imitate that of the ear), with a certain electric mechanism, whose function is to control the current by interrupting it in proportion to the degree of condensation or rarefaction of the impressed sound-wave. That fundamental principle is to be found in every transmitter used in every existing telephone exchange in Great Britain to-day. In the receiver he had two alternative principles, one of which survives in the modified instrument of Graham Bell, namely, that of employing an electro-magnet—a coil of wire wound round a core of magnetic metal—to translate the electrical vibrations of the current into mechanical vibrations in an armature of iron. Reis used as armature an iron bar—the more modern instruments have an iron plate, but the principle of action is identical. All that is really essential in the transmitter, and all that is really essential in the receiver—the varying degree of interruption imposed by the voice on the current at one end and the varying degree of attraction imposed by the electro-magnet on the armature at the other—is to be found in Reis's invention; all the rest is not essential, and may be varied in thousands of ways. The injustice of denying him the credit of his invention is the more flagrant since he is no longer living. To rob the living of the fruits of their own thought and genius is a crime; to rob the dead is a criminality doubly detestable. All honour to Bell and to Edison for the brief recognition they have each personally given to the labours of Philipp Reis. But for those who, for pecuniary or other ends, despoil the dead, and in the face of evidence of contemporary witness and contemporary works deny that the deceased inventor ever intended the telephone

Digitized by Google

which he invented to do that for which he designed it, for these, I say, no condemnation is too strong.

Lastly, I observe from public advertisements that Sir F. J. Bramwell, F.R.S., is to lecture on telephones before the Institution of Civil Engineers on March 1. As Sir Frederick is always on the side of the angels, I shall be curious to hear what he will have to say concerning the inventor of the telephone.—Yours, &c., SILVANUS P. THOMPSON.

Bristol,
Sunday, Feb. 25, 1883.

[We gladly insert Professor Thompson's letter, especially as he would seem to be in possession of information which has not yet been made public. So far as the evidence here adduced by him tends to modify any statement in our leading article we accept the correction, not only with a good grace, but with extreme pleasure, taking leave, however, to put our own estimate on the nature and value of the correction. We never denied that Reis "attained a certain degree of success;" the question is what was the *kind* of success aimed at and attained? And this question, we take leave to point out to Professor Thompson, is not affected in the least degree by whether Philipp Reis is dead or alive. If our esteemed correspondent seriously believes there are people who would "despoil the dead" [Reis] "for pecuniary or other ends" the best thing he can do is to let the world know all about Reis's invention. We shall be happy to assist him in giving it publicity, even at the risk of being accused of despoiling the living—by people who disagree with Professor Thompson.—ED. *E.*]

AN ARC LAMP TO BURN AT ANY ANGLE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should be very much obliged to you or any of your subscribers who could inform me if there is yet invented an arc lamp that will burn in any other position than vertically. It must have no clockwork, &c., near the centre of light, and, therefore, the carbons and their holders must be long, and the lamp must be capable of being used with very powerful currents. No lamp where the upper carbon falls by gravity or the length of the arc regulated by weights would answer the purpose.—Yours, &c., INQUIRER.

NEW TELEPHONE SWITCH BELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Knowing that you advocate "honour to whom honour is due" in your columns, in the name of fair play I desire to state a few facts. There are about a thousand subscribers in connection with the Manchester Telephonic Exchange. All of these are provided with two press buttons on their instruments—an ordinary (white) one in the switch bell, and a "commutator" (black) one contained in a separate box wood case. They "call" the central with either, but when "through" they only use the white one to ring each other. When finished talking, they press the black button, which, sending a "reverse" current, actuates a polarised annunciator in a derived circuit at the central office, thus signalling "off." This system has been in use for three years, and prevails in no other telephonic exchange. It elicited praise from M. Niaudet, of Paris, who has seen and examined it. It was devised and arranged entirely by Mr. Poole, electrician to the Lancashire and Cheshire Telephonic Exchange Company (Limited), at the head-office, Manchester. Now, in your issue of the 10th, there is a sketch and description of a new telephone switch bell. It is shown in your last issue to be the joint design of Messrs. Volk and Haworth, and claims to be original and part of a system described above. It would not have detracted much from the ingenuity of these gentlemen had they admitted that this feature in it was an adaptation and not an original invention. I would point out that it is a doubtful advantage to ring with the telephone off the hook, as the battery has then one cell short circuited through Blake primary, also that the hook does "make" and "break" bell and secondary circuits, not a shunt. After reading your last leading article on the "battle of the carbons," I looked up dates, and found that Edison's claim dates from July, 1877, whereas Professor Hughes's publication only dates from May, 1878.—Yours &c., D. F. D.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you please insert this in your next issue, in reply to Mr. W. Banks's letter on page 347. He is quite mistaken about the bell recently described being like the one he made ten months ago, and now in his possession. That bell has the ringing key springs in the cover, which is attached by four screws, these screws making the electrical connections between the springs and the rest of the apparatus. I at first made a similar apparatus for Mr. Haworth, and when we were talking the matter over we came to the conclusion that, providing room could be found, the springs would be best on the back of the case, as any electrician can see that testing for a fault was not simplified by having first to break four circuits in the bell. The result was I made the bell illustrated. I do not claim any invention in even new parts, but simply putting the same requisite parts into a more practical article from a commercial and electrical point of view. Take the case of the locomotive, those made forty years ago had practically the same parts, but I fancy the designers of modern engines can claim some little credit. Or, supposing I wish a house built, I might give the architect the size and number of rooms, where doors and windows, &c., had to be, but I fancy the architect and the builder would consider it their work.

I find from sad experience that if a sketch and description is handed to a manufacturer, who has then to work out the details, and make the whole into a practical thing, that what he, the manufacturer, has done counts for very little, and the sketch and description have done it all. Of course, if working drawings are given and followed the credit, or otherwise, does not rest with him.—Yours, &c., M. VOLK.

ACCUMULATORS AND MR. EDISON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Great importance will attach to Mr. Edison's statements quoted in *The Electrician*, Feb. 17, because they are his; but it appears to me that in this case the "Wizard of Menlo Park" is merely repeating what a few of our own countrymen have said many times during the last year. As long ago as December, 1881, accumulators formed the subject of a most interesting correspondence carried on between some of the electric companies and myself (at that time I was considering the question of fitting up my country house with incandescent lamps—a question still undecided); and among the letters I received was one from the manager of the Electric Light and Power Generator Company, dated Christmas Day, '81, in which the real state of affairs was for the first time pointed out to me in language as clear and certainly as forcible as that quoted in the last number of your excellent journal. I cannot decipher the gentleman's name, and the letter itself is too long to reproduce altogether; but if you think the following extract would interest your readers, perhaps you will see no harm in giving it a place in your columns:

"Why on earth wait until accumulators are perfected? It may take years to produce a thing that shall be worth its weight in lead, and I feel certain that long before the happy time arrives we shall have learnt to do better without them than with them. Believe me, accumulators are a delusion and a snare, and I fear that what has been said about them by persons whose one desire it is to make money by promoting companies will very seriously delay the introduction of electric lighting. Looking at the subject purely from the point of view of a mechanical engineer, I can think of no large scheme which cannot be carried out without the aid of secondary batteries. I grant that, if an *efficient* accumulator could be made for about £20 a ton, there are occasions when it might be *convenient* to use it, but, if cost is to be regarded (first cost, cost of attendance and renewals), duplicate engines and

Digitized by Google

machines will always prove the cheapest. The larger the installation the more complete can it be made, and the less excuse there would be to use accumulators. Any one who will go into this matter fully and without sentiment will find that I am dealing with sober facts; if I might, however, be allowed to indulge in fancy I should be inclined to say that the accumulator of the present day is the invention of the devil."

Many persons have spoken to me in the same strain during the last twelve months, and I suppose there must still be a great deal of truth in the above statements, or we should not have them confirmed by so high an authority as Mr. Edison. I enclose my card, and remain—Yours &c., W.

London, W., Feb. 20, 1883.

THE (ELECTRIC) CONDUCTIVE AND INDUCTIVE CIRCUITS GEOMETRICALLY ILLUSTRATED.

BY F. C. WEBB, M.I.C.E.

(CONTINUED FROM PAGE 203.)

If the line is composed partly of a conductor A B (Fig. 47), having electrostatic capacity, and partly of the conductor B D, having practically no electrostatic capacity, then the

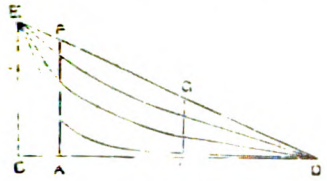

FIG. 47.

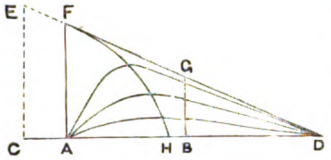

FIG. 48.

lines of potential at any moment during charging will form curves, with their concavity upwards in A B, and straight lines in B D; and in the same way, during discharge, the lines of potential will be curves with their concavity downwards in A B, and straight lines in B D (Fig. 48). The point of maximum potential will traverse a curve now terminating nearer to B than to A, and the greater the resistance of B D is in comparison with A B the nearer will the end H of this path

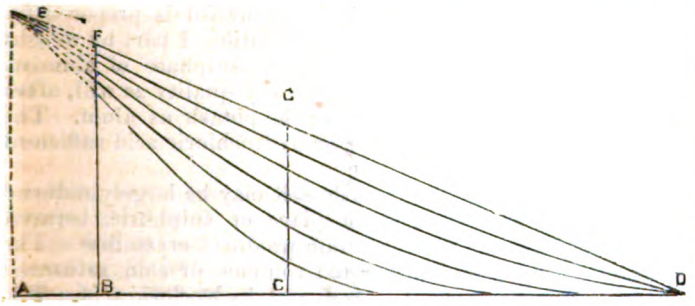

FIG. 49.

approach to B, but can never touch B, unless the resistance B D is infinite—*i.e.*, when the line is insulated at D. If the part B C (Fig. 49) of the circuit has no electrostatic capacity, and the part C D furthest from the battery has, then the lines of potential during charging will be straight lines in B C and curves in C D as shown in the figure. And during discharge the point of maximum potential will almost instantly change from F to G (Fig. 50), and then pass in a curve to some point H. The point H where the path of the point of maximum potential terminates will be much nearer to C (the junction of the electrostatic capacity conductor with the conductor of no electrostatic capacity) than that same point was to earth A in Fig. 41, showing that a greater portion of the charge now goes out at the distant end D.

We may in the same manner see that if we had a circuit, of which there were three parts, the two end ones having no electrostatic capacity, and the centre one having capacity, the potential lines at any moment during charging or discharging would be straight lines in the two end ones, and curves in the centre part.

Turning, now, to another subject—that of a circuit in which neither pole of the battery is to earth, but each connected to a conductor, having its other end to earth, it is useful to see how to draw the potential line in such case. Let A B (Fig. 51) be the resistance of the battery, B C one conductor to earth at C, and A D the other conductor to earth at D. Then, if A is the negative pole, we must erect at D the electromotive force D H, and joining H C, cutting a perpendicular at B, we get B E

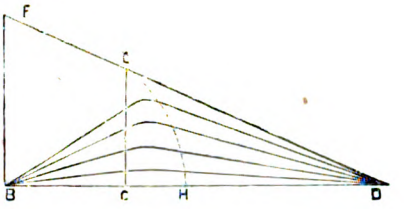

FIG. 50.

as the positive potential at B; and, drawing D F parallel to H C, cutting a perpendicular dropped from A, we get A F as the negative potential at A, from which, knowing our number of elements, it is easy, by dividing the line A B properly, to obtain the steplike series of lines which represent the potential line in the battery. If the line B C was removed and B L substituted, then in the same manner we should get the figure L O K D. It will be observed that, in the second case constructed, the line of potential is everywhere steeper than before, showing an increased current in the circuit. Also that, as the potential at B has dropped more than the potential at A has increased (negatively), the total difference of potential between the two poles has decreased.

If a perfectly-insulated battery has its poles connected by a well insulated line of similar electrostatic capacity throughout, then the point of no potential will be equidistant from each pole, or, in fact, in the centre of the line, and we might touch that point to earth without in any way altering the distribution of the potentials. But if the line has unequal capacity, then the point of no potential will no longer be in the centre of the line, but will be somewhere in the part that has the greatest capacity. Thus, if in Fig. 52 we suppose the circuit opened out in the battery, and B H resistance of battery and H E the electromotive force, proceeding as before we should get L C O D L as the line of potential if the conductor had equal electrostatic capacity throughout,

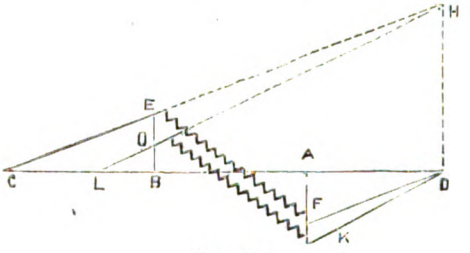

FIG. 51.

and O as the point of no potential, which we could touch to earth without producing any effect. But if O B was a conductor of considerable electrostatic capacity, and A O a conductor of no capacity, then the point of no potential would be at R, half-way between O and B, and the line of potential would be P M R N P. If, when O was the point of no potential, we touched the circuit to earth at R, the point of no potential would change to that point, and a quantity of electricity would be neutralised, represented by the parallelogram C M N D. Thus, if we had a perfectly insulated electric light circuit, with machine also perfectly insulated,* there will always, with a continuous current machine

* These conditions, I believe, rarely, if ever, exist, as the machines and lamps all leak, even if the lines are well insulated.

Digitized by Google

and lamps in series, be one point which we can touch with impunity, but if we touched any other point we should receive a momentary current, produced by the discharge of a charge equal to the capacity of the whole line multiplied by the potential at that point. That point would then become the point of no potential, and could give no further shock until the point of no potential had, by touching some other part to earth, been transferred to that part. In an electric light circuit with lamps in series the primary or natural point of no potential will be in the centre of the resistance of the circuit, if the lamps are equally distributed along the circuit. But if they are connected all in one out-going wire, then the point of no potential will be in the return wire. As, however, electric light circuits in practice invariably leak fearfully the point of no potential will in reality always depend on the position of the resultant of all the leaks.

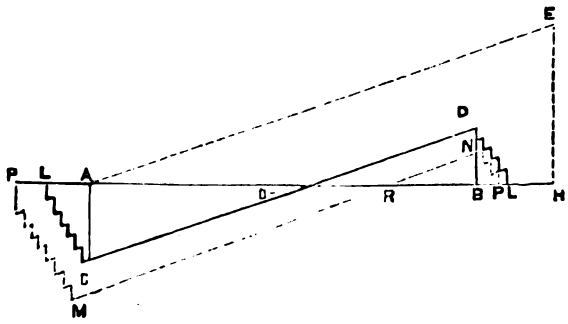

FIG. 52.

In a submarine cable in the factory tanks, when it is possible to insulate the battery perfectly, the distance of a fault having a very high resistance could be determined by measuring the potentials at A and B after the battery had been in circuit for such a time as to allow the point of no potential to move, as it would do in a short time, to the position of the fault, or resultant of the faults if more than one exists.

BICHROMATE OF POTASH IN BATTERIES.

BY. J. T. SPRAGUE.

The reactions of chromium are so complicated, and subject to such variation under changes of temperature and concentration, that it is by no means easy to be certain as to what occurs in these batteries. The usual solution is one of bichromate of potash with sulphuric acid, the proportions of which are very commonly given incorrectly, and should be different according to whether the solution is to be used in a porous cell, separated from the zinc, or as a single solution.

The salt itself is not a true double salt, like bisulphate of potash, which contains hydrogen as half the base, and is really a combination of sulphate of potassium and sulphate of hydrogen $\frac{K}{H}\}SO_4$. It is a union of potassium chromate with chromic anhydride, and its proper expression is $\left.\begin{matrix}K_2CrO4\\CrO_3\end{matrix}\right\}$. It is commonly supposed that the effect of the addition of sulphuric acid is to convert the potassium salt into chromic acid and sulphate of potash. But be the preliminary action what it may, the effect of the action of the battery is to convert the salt into chrome alum. The usual modern formulæ rather disguise this action, which is, however, quite intelligible when we regard an alum in the old fashion as a combination of a sesqui-sulphate $M_2^{iv}\cdot 3SO_4$, with a proto-sulphate M'_2SO_4 crystallising with 24 atoms of water. The tetratomic metal, uniting two atoms, so as to have a valency of 6, being either alumina, iron, chromium, &c., while the monatomic base is usually an alkali, potassium, or ammonium.

My unit of current, the "chemic," or 1 grain equivalent per 10 hours, affords a clear insight into these reactions and their electrical relations, and it should be understood that the term "unit" means in this paper that quantity or current corresponding to 1 grain equivalent of chemical action, and represents the coulomb or ampere divided by 5·68, according to the value accepted till recently that a coulomb represented ·0000122 gramme of hydrogen. The weights attached to the formulæ, therefore, mean grains for my purpose, and the reaction can be stated as

$$\left.\begin{matrix}\left.\begin{matrix}K_2CrO_4\\CrO_3\end{matrix}\right\} + 4H_2SO_4 = \left.\begin{matrix}K_2SO_4\\Cr_2(SO_4)_3\end{matrix}\right\} + 4H_2O + 3O\\ 295\cdot \quad 392\cdot \quad 567 \quad 72 \quad 48\\ 3Zn + 3H_2SO_4 = 3ZnSO_4 + 3H\\ 195 \quad 294 \quad 483 \quad 6\end{matrix}\right\} 3H_2O.$$

This represents 6 units of action, requiring in all 1 molecule or atom of the salt, 7 of acid, and 3 of zinc, to be consumed, or about 50 grains of bichromate per unit. Unfortunately, the electromotive force falls and the internal resistance rises as the alum accumulates, and owing to the insoluble nature of the materials, the solution is weak, and a pint of it is only equivalent to 25 units. However, to produce it the salt should be dissolved in hot water and allowed to cool, when it will contain about 3 ounces to the pint; it requires about one-sixth its volume of sulphuric acid, which is best used half at first and the rest when strength fails, and the acid must be employed in the proportions of 4 to 3, as shown in the formula if the zinc is in a separate porous cell.

The objections to this solution led Mr. FitzGerald to adopt the chromate of calcium, which ought to be obtainable at a price below that of the potash salt if there were a demand for it, but unfortunately it is not in the market, though for many purposes it would be fully as useful as the other. It can be made from the potash salt by dissolving 5 parts in hot water and adding 1 part of pure quick lime, slacking it just before use, and $2\frac{1}{2}$ parts of sulphate of lime (plaster of paris). A yellow powder precipitates, and its atomic weight is about 180, which represents about 60 grains per unit. It takes one atom more acid than the potash salt, the reaction being

$$\left.\begin{matrix}CaCrO_4\\CaCrO_4\end{matrix}\right\} + 5H_2SO_4 = \left\{\begin{matrix}2CaSO_4 + 3O\\Cr_2(SO_4)_3\end{matrix}\right\} 3H_2O.$$
$$3Zn + 3H_2SO_4 = 3ZnSO_4 + 6H$$

On the addition of the acid one-half of the lime is precipitated as sulphate, and the solution becomes a true bichromate or di-hydrochromate of lime, from which the remaining lime precipitates as the action proceeds. This solution can be made much more strong than the other, and does not crystallise. On the large scale it would have the advantage that its residues can be easily converted into valuable products as colours.

Another solution which might be useful is prepared by adding to 3 parts of bichromate in solution, 1 part by weight of oil of vitriol, and $6\frac{1}{2}$ parts of sulphate of alumina ($Al_2(SO_4)_3 + 18H_2O$), or so much of any quality as will, after concentration and cooling, remove the potash as alum. The solution will require sulphuric or hydrochloric acid sufficient to satisfy the reactions.

The objections to the potash salt may be largely reduced by using hydrochloric acid in place of sulphuric, because neither the zinc nor the chromium products crystallise. The solution can be made with equal volumes of cold saturated solution of bichromate of potash and hydrocloric acid. The reaction is probably

$$\left.\begin{matrix}K_2CrO_4\\CrO_3\end{matrix}\right\} + \begin{matrix}2HCl\\2HCl\end{matrix} = \begin{matrix}2KCl + H_2CrO_4\\H_2CrO_3Cl_2\end{matrix}$$

The formation of potassium chloride, chromic acid, and a chloro-chromic acid, which may be regarded either as a union of the hydro-chloric acid and chromic anhydride, or as chromic acid in which Cl_2 replaces one atom of oxygen. These now react thus—

$$\begin{matrix}H_2CrO_4 + 2HCl = CrCl_2 + H_2O + O_2\\H_2CrO_3Cl_2 = CrCl_2 + H_2O + O_2\end{matrix}$$

Giving 4 atoms of oxygen to take up the hydrogen derived from the action of 4Zn + 8HCl.

The complete reaction may be expressed also as

$$\begin{matrix}\left.\begin{matrix}K_2\\CrO_4\\CrO_3\end{matrix}\right\} + \left\{\begin{matrix}2HCl\\2HCl\\2HCl\end{matrix}\right\} = 2KCl\\ 295 \quad + \quad = 3H_2O + 2CrCl_2\\ 260 \quad 4Zn + 8HCl = 4H_2O + 4ZnCl_2\end{matrix}$$

511 HCl 14

Digitized by Google

The use of hydro-chloric acid in place of sulphuric gives about 5 per cent. higher E.M.F., and the working is also more steady.

Voisin's red salt is useful in some cases, giving the same E.M.F. with a little higher resistance and a more constant current. It consists of

$$\underset{140}{Na_2SO_4} + \underset{686}{7H_2SO_4} + \underset{295}{K_2Cr_2O_7}$$

which is probably converted into

$$2NaHSO_4 + 2KHSO_4 + 2CrO_3 2SO_3 + 7\,\text{aqua}.$$

It is obtained by heating the acid, stirring in the sulphate of soda and then the bichromate of potash by degrees, then pouring into a mould to cool.

NOTE ON THE SUPERPOSITION OF CURRENTS.

BY THOMAS H. BLAKESLEY, M.A., ASSOC. M. INST. C.E.

The following generalisation is one which I have been for a long time in the habit of using in calculating the currents in various parts of a system of conductors, but I am informed that it is not given in the text books on electricity. This statement is true so far as I have been able to verify it; and even in Clerk Maxwell's treatise the rule is not given explicitly, though it may very likely be possible to find it involved by implication in some parts of that work. So, perhaps, it may be of interest.

If any reticulated system of conductors whatever contain at various points sources of electromotive force of different values, the resulting current in any conductor is always the algebraical sum of the currents which would be produced in that conductor by the different sources of electromotive force acting separately.

Thus, let Fig. A represent a system of conductors con-

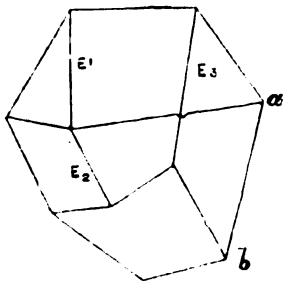

FIG. A.

taining at the points E_1, E_2, E_3, &c., sources of electromotive force which may be denominated by these letters. Now, considering any conductor *ab*, the rule asserts that the resulting current in *ab* is the sum of a number of currents which we may call c_1, c_2, c_3, &c., of which c_1 would be produced in *ab* supposing E_1 to maintain its value, but all the other sources of E.M.F. to be reduced to zero; and c_2 would be produced in *ab* supposing E_2 to maintain its value, but E_1 and all the others to be reduced to zero, and so on. That is to say, the effect of each source in producing an increase or decrease of current in any conductor is independent of the presence in the same system of other sources of E.M.F. And this is true, even if the conductor considered contain a source of E.M.F. It will also cover the case of leakage by conduction through the medium in which the system is situated, provided the resistance of the medium is constant, and, therefore, independent of the currents through it, and of the potentials producing those currents.

The cutting of any conductor carrying a current is equivalent in its effects upon the rest of the system to introducing a source of E.M.F. into the particular conductor, tending to send a current in the opposite direction to the actual current. For, let C be the current in a conductor, *ab*, of a system. Then it is clearly possible to suppose a source of E.M.F. introduced into that conductor which would reduce the current to zero. Suppose that this has been done. Then, since there is no current passing in the conductor *ab*, it may be cut without affecting the rest of the system, and when this has been effected the source introduced may be taken away from the end of the now divided conductor. Thus, the system has really only been modified by the division of the conductor *ab*, and this is equivalent to the introduction of an E.M.F. acting in opposition to C, the existing current, and of such a magnitude as to annihilate it.

Let there be six conductors (Fig. B) joined to each other like the edges of a tetrahedron or triangular pyramid.

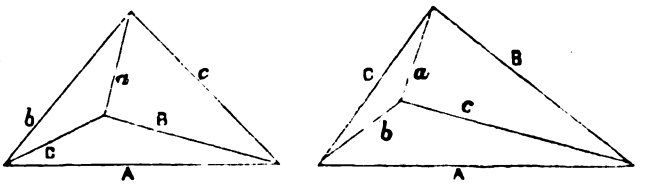

FIG. B.

Let the conductors A B C form one of the triangular faces, and let *a b c* be the three other edges which do *not* cut A B C respectively.

I shall also take these letters to represent the resistances of the various conductors.

Suppose a source of E.M.F. to exist in B. Then there will obviously be no current in *b*, if $a : c :: C : A$. Suppose this relation to exist, but instead of the source of E.M.F. being in B, let it now be in A. Then there will exist certain currents in *b* and B. Now cut B. This is equivalent to introducing an E.M.F. into B, as we have seen. But, by the rule of the superposition of currents, it does not *alter* the current in *b*, since it could not, acting singly, *produce* a current in *b*. Thus, the division of B does not affect the current in *b*, so long as $a : c :: C : A$, which constitutes Colonel Mance's method of finding the resistance of a source occupying the position of the source in A, the truth of which may be proved in other ways.

ON THE MEASUREMENT OF ELECTRICITY FOR COMMERCIAL PURPOSES.*

BY JAMES N. SHOOLBRED, B.A., M.I.C.E., &C.

Mr. Shoolbred began by stating that his remarks were more especially intended to deal with the commercial question raised by the Electric Lighting Act, 1882. He then described the various electrical units as adopted by the International Congress of Electricians, held in Paris in 1881, viz., the ohm, volt, ampere, coulomb, and farad, and those suggested by Dr. Siemens in his address to the British Association last year, viz., the watt and joule. Continuing, Mr. Shoolbred said: Although the unity of quantity, as defined, is the coulomb, yet it is sometimes found more convenient to express measurements of quantity in terms of the current or rate of flow in amperes. Thus, it is more convenient sometimes to say "one ampere-hour" than "3,600 coulombs," as the result of work done by a current of one ampere flowing continually and uniformly for the space of one hour. The product of the current expended, in ampere seconds, or of this amount of quantity expended in coulombs, by the electrical pressure of the same, expressed in volts, gives the electrical energy expended, or power of the supply expended in watts. The electrical energy is, therefore, represented by the product of volts × amperes × time; or, by the product of volts × coulombs; or, expressed algebraically, $W = E\,C\,t = E\,Q$. The following are the equivalent expressions for the same amount of energy, only expressed in other terms; some of which may, perhaps, be more familiar:—

Energy expended per second.

$$\text{Volt} \times \text{ampere} = \begin{cases} 1 \text{ watt.} \\ \frac{1}{1\cdot355} \text{ foot-pounds.} \\ \frac{1}{0\cdot81} \text{ kilogrammetres.} \\ \frac{1}{736} \text{ force cheval (French horse-power).} \\ \frac{1}{746} \text{ horse-power, indicated.} \end{cases}$$

It is suggested in some of the (draft) provisional orders for the supply of electricity now before the Board of Trade, that the

* Abstract of a Paper read before the Society of Telegraph Engineers and of Electricians, Feb. 22, 1883.

Digitized by Google

unit of price to be charged should be based "on the energy contained in a current of 1,000 amperes flowing under an electromotive force of one volt during one hour;" or, in other words, the unit might be put as 1,000 volt-ampere-hours. Since the ampere-hour is another way of saying 3,600 coulombs of quantity of electricity supplied, this above expression may be put thus, as representing the value of the about unit:—

Work Done.

1,000 volt-ampere-hours = { 3,600,000 volt-coulombs. / 1,000 watt hours. / 1·34 horse-power hours. / 2,653,200 foot-pounds. / 1·36 force-cheval-heures (French horse-power hours nearly). / 100 kilogrammetres.

Put in terms more in accordance with actual practice, the above unit might mean the supply for one hour of a current of 10 amperes with an electromotive force of 100 volts. To arrive at a due evaluation of the supply of electric energy, it is evident that the measurement of each of these two factors (in volts and amperes respectively), should be effected either separately or combined; and also that a continuous and cumulative record should be kept of the supply as it proceeds. Many instruments exist for the measurement of the above elements, at any particular time, but without any means of continuously recording such measurements. These evidently, except under certain conditions, cannot comply with the commercial conditions required for ascertaining the amount of supply. It is only, therefore, instruments furnished with means of continuously integrating, or recording the successive progressions of the supply, or instruments to which such recording apparatus can readily be attached, that come properly within the scope of this paper. To measure with completeness for commercial purposes a supply of electricity will entail, therefore, a continuous record of each of the two elements just referred to—current and pressure, either separately or combined. In the supply of towns, however, the question for the consumer may, and will most probably, be much simplified by causing one of these elements—that of pressure—to remain constant, since it is very likely that a constant standard pressure of supply will be fixed by the Government in granting the several provisional orders. It has been thought advisable to precede the description of the recording or registering instruments, which alone are meters in the commonly accepted sense of the word, by an enumeration of some of those non-recording instruments which are in more general use, since they suffice for present exigencies. This short descriptive enumeration is even almost necessary, since most of these instruments, by the addition of some recording apparatus, or appliance by which the element of time can be integrated, may be made to enter into the class of registering meters. Indeed, some of them already possess their representative in this second class, or else have given rise to some modification which has complied with the requirements in the latter case. Thus, any current or ampere measurer may be converted into a record of quantity, or a coulomb meter, by the integration of the time during which the current has flowed, and, similarly, any power or volt-ampere measurer may become a register of work done by means of the addition of the elements of time. Again, volt or pressure measurers will always be required in any case where a check is required upon the actual difference of potentials, or electromotive force of the supply, and this may arise from a variety of causes.

NON-REGISTERING INSTRUMENTS.

Current Meters.—Siemens', electro dynamometer; Professors Ayrton and Perry, am-meter; Sir Wm. Thomson, current galvanometer; Captain Cardew, R.E., low resistance galvanometer; Dr. Obach, tangent galvanometer; Marcel Deprez, galvanometer.

Pressure Meters.—Profesors Ayrton and Perry, volt-meter; Sir Wm. Thomson, potential galvanometer; Siemens', torsion galvanometer; Marcel Deprez, galvanometer.

Power, or Energy, Meters.—Professors Ayrton and Perry, power meter; C. V. Boys, power meter.

REGISTERING METERS.

Quantity, or Colomb, Meters.

1. *Electrolytic.*—T. A. Edison, total deposition; T. A. Edison, alternations of deposition; J. T. Sprague, alternations of deposition.

2. *Mechanical.*—Dr. J. Hopkinson, rotating meter; C. V. Boys, vibrating meter; Theos. Varley and Greenwood, disc meter; Professors Ayrton and Perry, fluid friction on magneto-electro-motor; T. A. Edison, fluid friction on magneto-electro-motor.

Energy, or Work, Meters.—Professors Ayrton and Perry, erg-meter; C. V. Boys, energy meter; Deprez-Abdank, energy meter.

Mr. Shoolbred here entered into a description of the principle and working of some of the above-named meters, amongst others those of Edison, Sprague, Boys, Ayrton and Perry, and Hopkinson. Of these, all but the latter have been previously described in *The Electrician*.* Of Hopkinson's current meter, Mr. Shoolbred said: This instrument consists of a thick wire coil, in the form of a solenoid, through which the current passes to be measured. The iron core of this solenoid revolves with its central shaft by the action of the armature of a small dynamo machine, placed at one end of the shaft. The core of the solenoid is in two parts; the lower is fixed to the shaft, while the upper is movable, being attached to a governor-ball arrangement, and sliding up and down the shaft in accordance with the variations in the rotation speed of the shaft. A shunt current passes through the dynamo and its armature, then up through the lower or fixed portion of the core, and (by contact only) to the sliding part, and thence to the framework of the apparatus. If the movable core be lifted, owing to the speed of rotation by the action of the governor balls, this circuit is broken, and the shunt current through the dynamo interrupted. Whenever a current to be measured passes through the coil, attraction, by means of its casing, takes place between the fixed and the movable parts of the iron core. This magnetic action, which is proportional to the square of the current, tends to keep the two parts of the core together and in contact, while the centrifugal force of the governor balls, which is proportional to the square of the speed of revolution, tends to break the contact by lifting the movable part. These opposite forces will, in working, balance one another, and the result is that the system revolves with a velocity proportional to the current through the coil. As the revolutions of the shaft are transmitted continuously by a train of wheels to a set of index dials, a record is thus kept of the quantity of the current that has passed. In the construction of the apparatus the weight of the core is taken off by springs.

In conclusion Mr. Shoolbred said:

For the reasons stated in the earlier part of the paper, it is probable that the supply of electricity in a town will be carried out at a certain defined standard pressure or electromotive force, which will be guaranteed to the consumer; and to assure the fulfilment of this condition special steps will be taken by the local or other authority.

The consumer need, therefore, but concern himself, as far as the supply he receives and has to pay for, with the quantity of electricity which he has made use of. In fact, the meter he makes use of to record it may be a coulomb meter. The work or energy meters will not be needed for general application, but only in special cases, where the complete record of the total electrical energy supplied is required.

In what form, therefore, will it be most convenient for these coulomb meters to present their record? or, in other words, upon what unit should that register be based for commercial calculation? With the sole exception of those meters based upon electrolytic action, and which simply present the total of the increments of the metal, which are proportionate to the total quantity of current which is passed, the record presented is the result of a series of mechanical actions indicative of the strength and duration of the electrical supply.

It is seen how these successive mechanical operations may be recorded in a cumulative way by the ordinary arrangement of a train of wheels; both in the case of those meters based upon electrolytic action, and causing periodical reversals in the direction of the current, and also in those where the action due to the current is a purely mechanical one.

There remains then but the question of the mode of graduation of the respective indicating dials.

The unit already referred to, as being proposed to the Board of Trade in several provisional orders, as "the energy in a current of 1,000 amperes with an electromotive force of one volt flowing during one hour," has been shown to mean 1,000 volt-ampere-hours, or 3,600,000 volt-coulombs.

As it is probable that one of these factors (the volt) being fixed and constant may be taken out of the commercial calculation for the consumer, it is worth while considering what dimensions the remaining factor (the coulomb) would assume under the ordinary conditions of practice, and, hence, what would be most convenient graduation of the dials to embrace these dimensions. But the commercial question requires also a financial expression in which to reckon these dimensions.

The maximum money value accompanying the suggestion of the above 1,000 volt-ampere-hours unit, and which is sought to be attached primarily to 100 of these units, is in some pro-

* Descriptions, with illustrations of these meters, will be found in *The Electrician* as follows:—Ayrton and Perry's meters, Vol. IX., pp. 373 and 413; Sprague's meter, Vol. IX., p. 67; Edison's meter, Vol. IX., p. 65; Boys's meter, Vol. VIII. p. 251.

Digitized by Google

visional orders 70s., in others 75s. Though it would be quite out of place in this paper to attempt to assign any financial value for the supply of electricity, yet for the nonce, and in carrying out the analysis of the above unit—as it might work under the conditions of actual practice—it is necessary to assume a money value. In the annexed table, which takes into consideration the effect of different rates of electromotive force according as they may be fixed, 70s. is assumed as the money value for 100 units of 1,000 volt-ampere-hours each.

Comparative Values of Supply of Electricity per 100 *Units* (*of* 1,000 *V.-A.-hours*) = £3 10*s.*

(1,000 volt-ampere-hours = 3,600,000 volt-coulombs.)

E.M.F. Volts.	Price. 100 Coulombs.	10,000 Coulombs.	100,000 Coulombs.	1,000,000 Coulombs.
	Pence.	Pence.	s. d.	£ s. d
100	·23	2·33	1 11·3	0 19 5
110	·26	2·57	2 1·7	1 1 5
120	·28	2·8	2 4	1 3 4
130	·3	3·03	2 6·3	1 5 3
140	·32	3·27	2 8·7	1 7 3
150	·35	3·5	2 11	1 9 2
160	·37	3·73	3 1·3	1 11 1
170	·4	3·97	3 3·7	1 13 1
180	·42	4·2	3 6	1 15 0
190	·44	4·43	3 8·3	1 16 11
200	·46	4·67	3 10·7	1 18 11

The prices in this table are based on the assumption that the price per coulomb unit remains at the same rate, irrespective of the intensity of the electromotive force. As a matter of fact, the amount of the latter ought certainly to be taken into account in fixing the sale price.

Thus, with a pressure at 200 volts, the price for a certain number of coulombs ought not to exceed two-thirds of that of the same supply at 100 volts of pressure; in consequence of the economy in the former case, in the distributing mains, and in general working expenses.

From a careful consideration of this table, it would appear that the amount of 100,000 coulombs would form a convenient unit of value whereby to reckon the commercial price. It would also serve as a basis of graduation for the indicating dials of the meters, with subdivisions to $\frac{1}{10}$ and $\frac{1}{100}$ parts.

The diagram (shown at the meeting) gives an arrangement of indicating dials, graduated in the first case with the unit suggested in the provisional orders, 1,000 ampère-hours; in the second the unit is 100,000 coulombs as just suggested. The E.M.F. in each is taken at 100 volts. The proportion between the two systems of graduating in the present instance is as 3·6 to 10 (3,600 being the number of coulombs which is the result of the flow of a current of one ampere for one hour).

$\frac{3{,}600{,}000 \text{ coulombs}}{100 \text{ volts}}$ is, therefore, the actual quantity value of the first unit (1,000 ampere-hours), as against 100,000 coulombs, the quantity contained in the second unit.

The values in C.-G.-S. units are { Volt-ampère-hour unit = 10^{10}. Coulomb unit 10^{4}.

The advantage of the coulomb unit is that it expresses an actual quantity, whereas the ampere-hour unit is but a time rate, which, as a matter of fact, has to be translated into its corresponding quantity.

The coulomb method of graduation could be applied *uniformly* to all quantity meters whereon they might happen to be afterwards used, inasmuch as the special rate of electromotive force (or standard pressure) in each particular locality would be taken into account in the price there charged for the electric supply. This uniformity in manufacture would further reduce the expense of this, already the simpler, form of registering meter.

With the volt-ampere method, to use a quantity meter (as shown in the index-dial diagram) requires the exact position of the unit to be set according to the particular electromotive force with which it is used; inasmuch as the quantity-record is only one factor in the unit. This limited use of each particular recording meter would tend to create error and confusion.

An energy meter alone would supply a complete record of the volt-ampere-hour mode of measurement; and this is a form of meter which involves a clock or some other time record, and consequently is a more expensive apparatus, and one requiring an amount of attention from the consumer which it would be impossible, in many cases, to expect.

Thus, although the volt-ampere system may present, *theoretically*, a complete and convenient means of recording the supply of electricity, yet, *in actual practice*, the coulomb system would meet all wants, and be more suited to general application.

ON ELECTRIC LIGHTING FOR WORKSHOPS AND LARGE SPACES.*

By Mr. Andrew Jamieson, A.M. Inst. C.E., F.R.S.E., &c., Principal, College of Science and Arts, Glasgow.

(concluded from page 354.)

The connections of the Brush machine have hitherto been considered rather a mystery, but I hope that the theoretical diagram given in Fig. 4, along with the following description, will make them clear to you. The armature coils A A and commutator parts C C are shown in the diagrams at right angles to their position in the machine, with a view to facilitate tracing the connections. The opposite coils, whose inner ends are connected together, are numbered (1 − 1′), (2 − 2′), (3 − 3′), and (4 − 4′), while the opposite plates on the commutator to which the coils are respectively connected are similarly marked. Starting from armature coils (3 − 3′) and following the direction of the arrows which indicate direction

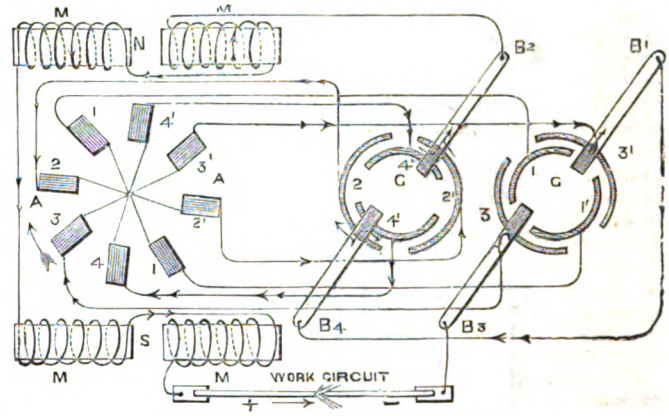

Fig. 4. Diagram of Brush Machine.

of current, we come to commutator plate 3′ to brush B_1, then to brush B_4, where the current splits at plates 2 and 4; by 2 to coils (2 − 2′) to plate 2′ and by 4 to coils (4 − 4′) to plate 4′ where brush B_2 unites the currents again and leads them to the electro-magnates M M M M, through which it passes to the (+) carbon or work circuit across the arc where light is produced, and along the (−) carbon to brush B_3, commutator plate 3, back to armature coils (3 − 3′), thus completing the circuit. It will be seen that each pair of coils as they come into the position (1 − 1′) are cut out of circuit, thus reducing the armature resistance mentioned before.

The Crompton-Bürgin Dynamo is a very practical and useful modification of the Gramme dynamo. It is constructed either for arc lighting or for incandescent lighting purposes. When constructed for the latter work, the electro-magnets are specially wound on the combined series and shunt principle, with the view of rendering the generation of the current automatically proportional to the number of lamps in circuit, and keeping the electromotive force constant for a constant speed.†

This machine has several advantages—1. It lies low, is well constructed, and free from vibration. 2. Armature coils easily made and repaired. 3. The armature admits of being accurately balanced and rapidly rotated. 4. The small number of *layers* of wire on armature rings, with a free circulation of air *between* the spokes, prevents undue heating.

We may here state that all dynamos on important circuits should be fitted with accurately indicating tachometers, or continuous speed indicators. This is a point which is too often neglected, although it greatly assists those in charge in keeping up a steady motion.

Conducting Wires or Leads.

These should, in all cases, be carefully proportioned to the strength of the current they may have to carry, and to the distance through which it has to be conveyed; for, when electricity flows through resistance, energy is spent in heating the matter through which it flows. For practical use, the heat generated by a current of electricity in time $T = C^2 R T \times 0{\cdot}2405$ (gramme degrees), where C = amperes, R = ohms, and T = seconds. Hence it is that if the conducting wire be too small for the current it has to convey, it will become warm, which still further increases its resistance—ultimately producing incandescence, and even fusion, endangering property by fire. Again, although the wire may have sufficient conducting power for the current, without undue heating at any part, yet its length, and consequently its resistance, may be so great that the total amount of heat generated, or energy misspent on it, will much reduce the efficiency of the system. (The rules laid down in the new Electric Lighting Draft Provisional Order were read and commented upon.)

Arc Lamps.

In dealing with electric lighting for workshops and large spaces, I need only consider arc lamps, as neither the incandescent nor semi-incandescent lamp is so suitable as yet. I shall describe a few of them in the alphabetical order of their names.

Akester's Lamp is one of the simplest forms of arc lamps that I have

* A Paper read before the Institution of Engineers and Shipbuilders in Scotland.

† A description of the principle of this machine appeared in the issues of *The Electrician* for December 16, 30; January 13, 27.

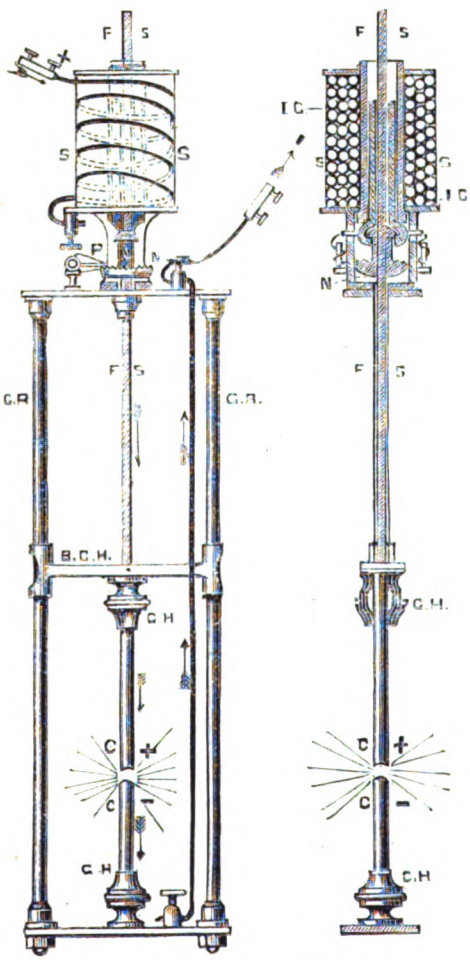
Digitized by Google

met with. It is only arranged to be worked as a single lamp, but there would be little difficulty in so winding a shunt coil, and fitting the extra necessary parts to it, as to make it serviceable to be worked in series with a large number of others of the same kind. Most of the modifications of arc lamps, of which there are so many patents, aim at keeping the + and − carbons at a uniform distance when in action, to produce a steady light. This is generally done by combined electrical and mechanical action.

Referring to Figs. 5 and 6, we see

S, S,	Solenoid coil of copper wire, No. 10 B.W.G., insulated by cotton and shellac varnish.
I, C,	iron core (hollow).
F, S,	quickly pitched six-threaded screw.
N,	nut with lower upturned edge milled.
P,	pall or lever held down by a bent spring.
C, H,	carbon holders.
C + C −	carbons 13 millimetres diameter.
G R, G R,	parallel iron guide rods.
B C H,	brass crosshead.

In this lamp the current, in passing from the dynamo to the upper carbon, traverses the solenoid coil S S, acting inductively on the hollow iron core I C, and sucking it upwards, thus lifting the upper from the lower carbon by engaging the nut N, which is fitted to the central screw F S. The milled edge of the nut comes against the lever pall P, and is thereby prevented from turning round, thus limiting the length of arc.



FIGS. 5 and 6.—Akester's Lamp.

As the arc burns longer the resistance of the circuit increases, the current thereby necessarily diminishes in strength, and the lifting power of the solenoid becomes less, allowing the iron core to drop a minute distance, just sufficient to clear the milled edge of nut N from the pall P, the nut turns round through a degree or so, which allows the carbon to drop a very small distance, the normal length of arc being in this way resumed. The above operation takes place so rapidly that the upper carbon is fed forward in almost perfect unison with the consumption, ensuring a steady light.

From tests which I made of this lamp an actual, not nominal, candle power of 2,250 candles, or 1,450 candles per horse-power at the lamp was obtained, the electricity being furnished by an A Gramme dynamo.

I would like here to explain and clear up an ambiguity which has arisen and which is very confusing to those not acquainted with electrical phraseology. When the expression, so many candles per "electrical horse-power," or so many candles per horse-power expended in the lamp, is used, it is to be understood that the electrical energy absorbed by the lamp, and developed in the form of heat and light, is according to the formula $\frac{E \times C}{746}$ (which we stated at the beginning of this lecture was an actual horse-power of 33,000 foot-pounds per minute). This takes no account whatever of the energy lost in transmission through the leading wires, or that absorbed by the dynamo, or that spent on the moving parts of the engine shafting and belting through friction, &c. It is considered fairly good work, in actual practice, if we get 60 per cent. of the horse-power, as indicated by diagrams taken from the steam cylinder, in the form of electricity, at the lamp carbons or arc. The loss of power in conversion and transmission may be roughly computed as follows:—

Loss by friction, &c., in engine, &c.	10 per cent.
,, in conversion of mechanical to electrical energy in dynamo, by heating, friction, &c.	20 ,,
,, by heating leading wires and lamp circuit coils	10 ,,
Total loss	40 ,,

One has, therefore, always to be on guard when inquiring "how much power such and such a lamp or system gives in the form of light;" and it is generally necessary to ask the question, "Do you mean so much cylinder horse-power, or so much dynamical horse-power, or so much in the form of electrical energy at the lamp?"

*Brush Lamp.**—Perhaps no lamp has been so extensively adopted as the Brush lamp in workshops and streets. Its popularity and success mainly depend upon the fact that it is arranged so that a large number can be included in series and worked from one dynamo. As many as 40 of these lamps have been worked, in numerous instances, by one machine, while the whole system is so adjusted by means of an automatic carbon regulator that one or more of the lamps can be extinguished or removed without endangering the others remaining in circuit. The only danger arising from using such a large number of lamps in circuit, placed in series, is the necessarily high electromotive force of the current. The normal electromotive force or difference of potential between the terminals of each lamp being 45 volts, 40 such lamps, *irrespective* of the leading wires and dynamo, require an electrical pressure of 1,800 volts, or about 2,000 volts including the dynamo and leads; and, therefore, the connections and leading wires should be well insulated, and the handling of the same should be done with care and caution. The normal strength of current is 10 amperes, so that each lamp absorbs energy to the amount of $E \times C = 45 \times 10 = 450$ watts.

I tested the candle-power, the other day, of one of the Brush lamps at the Aberdeen installation, where they have dispersed along Union-street, Market-street, &c., in a circuit of a mile and a half, 16 lamps of 2,000 (nominal) candle-power, and found it to give 567 candles, measured at an angle of 30 degrees from the horizontal. The lamps are placed on 20ft. wooden poles, and the centre of the arc of the one which I measured was 20ft. 10in. from the ground, which appeared to be a very suitable height for distributing the light. The lamp was fitted with clear glass globes, which, from various tests which I have made with clear glass, will reduce the candle-power about 10 per cent. of that given by the naked light. I also tested one of the 32 Brush lamps daily at work at Messrs. Mirrlees and Watson's engine works, where they use strongly frosted globes with a view to soften and diffuse the rays of light and render it more agreeable to work under. These globes reduce the candle-power about 50 per cent., and the mean which I got was 310 candles. The workshop engine is used, and it appears that 17 lamps are worked by one machine for an expenditure of 19 indicated horse-power, as measured by diagrams taken from the cylinder; or, say roughly, 1·1 indicated horse-power per lamp, or 54·5 per cent. of the horse-power developed in the cylinder is usefully employed in the form of electricity at the lamps.

The Crompton Arc Lamp.†—This is very suitable for railway stations and large spaces where a powerful light of 2,000 or more candles is desirable, and where plenty of elevation can be obtained.

Messrs. Crompton's firm state that they obtain by this lamp effective lighting for 200 square yards of station floor area, both at Queen-street Station, Glasgow, and King's Cross Station, London, for an expenditure of only one pound of coal per hour by using Messrs. Marshall and Son's economical engines. You have, no doubt, all witnessed the performance of this lamp at Queen-street Station, Glasgow, and I think every one admits that it is the best-lighted station in the kingdom. Mr. Hobson, the postmaster, is so well pleased with this lamp at the General Post Office that he has entered into a two years' working contract for the lighting up of the large spaces in the Post Office, while the smaller offices and rooms are to be lighted, within a couple of weeks, by means of Swan lamps.

I think arc lamps, both in railway stations and workshops, should be so placed with regard to distance apart and height that no part where work or business has to be carried on should have less light than that equal to one standard candle at 2ft. distance. For the Brush lamp, reckoning them as averaging 500 candles with clear globes, this would mean placing them at a height of 22½ft. and 26 yards apart, and would give a good light to read or work by, while not too strong or trying to the eyes. For streets, the Brush lamps might still be placed at a height of 22½ft. and about 60 yards apart, or with a minimum light at the further parts from the lamps of about equal to 1 candle at 4ft. distance. In workshops, streets, and large spaces, the lamps should be so placed zig-zag that the light from each tends to dispel or cancel, as far as possible, the shadows cast by the others.

It is worthy of mention that Messrs. A. and W. M'Onie, who have lately adopted the Brockie lamp (which was shown at the meeting), are able to photograph their working drawings by means of the electric light. They have fitted up a special room for the purpose, and obtain a clearly defined copy of a drawing 3ft. 6in. by 2ft. 6in. in twenty minutes.

Electrical Instruments for Measuring the Strength of Current and the Electro-Motive Force.

The development of electric lighting has necessitated the invention of special instruments for measuring stronger currents and greater electrical pressures than were demanded by those used for submarine and other telegraphic and scientific purposes, and we are fortunate in being able to place before you this evening the latest and best that have yet been produced, viz.:—Sir William Thomson's graded galvanometers, made by Mr. White, the well-known optician of Sauchiehall-street. (These instruments, and methods of using them, were described to the meeting.)

* A diagram, illustrating the action of this lamp, was given in Vol. IX. of *The Electrician*, p. 486.

† We have frequently illustrated the Crompton arc lamp. The latest improvements in its mechanism and working will be found illustrated and described in our issue for November 4, 1882, Vol. IX., p. 586.

Relative Cost of Electric and Gas Lighting for Workshops.

We now come to compare the cost of electric lighting and gas lighting.

There can be no doubt that the introduction of electric lighting has greatly spurred on inventors and gas managers to make more of the gas than formerly, and the consequence is that we have gas burners rivalling the electric light both in brilliancy and economy.

There are being fitted at the present moment to the Clyde Navigation Graving Dock a large number of Bray's powerful gas lamps. Also, the Clyde Trust has in operation one of Siemens's 400 candle-power lamps, and is having fitted up 20 of Siemens's patent regenerative 130 candle-power gas burners, in place of the former mode of lighting by 30 cowl-shaped crystal basins, each containing four No. 4 gas jets. Each of these systems of gas lighting has certain advantages which the other does not possess, and for each certain advantages are claimed against those of electric lighting. There can be no doubt but that the Siemens burner is more economical than Bray's, as far as the amount of light given out for a certain consumption of gas, for it is found that while the Bray lights give 5·7 candles per cubic foot of Glasgow gas, the Siemens burner—as we shall prove further on—yields 7·8 candles per cubic foot of the same gas; but then the Bray lights admit of being turned down to one small jet, when the full flame is not required, more readily than the Siemens burner.

From tests made by Dr. Wallace and myself of these Siemens burners, it appears that 408 candles are obtained from a consumption of 52·2 cubic feet per hour, or 7·8 candles per cubic foot; or, say, 39 candles for 5 cubic feet per hour, or an improvement in the economy of using gas of 46 per cent. over that of the best small burner which is used in testing the Glasgow 26-candle gas (*i.e.*, 26 candles for 5 cubic feet per hour).

Let us compare this with the Brush lamp under similar conditions as to globes and lanterns. We got 567 candles from the Brush lamp at Aberdeen, with clear globes.

Cndls. Cndls. Cb. ft.
∴ 408 : 567 :: 52·2 : X = 72·5 cubic feet per hour.

of Glasgow gas required by Siemens's burner to produce 567 candles. Now Glasgow gas costs 3s. 8d. per 1,000 cubic feet.

Cb. Ft. Cb. Ft. D
∴ 1000 : 72·5 :: 44 : y = 3·19d. for gas alone per hour.

To this we have to add, say, 20 per cent. on first cost of lamps and fittings (£30), as well as depreciation on same—or £6 per annum. Allowing this to be distributed over 3650 hours, or 10 hours' lighting per day, we have

Hours. Hour.
3650 : 1 :: 1,440d. : Z = 0·39d. per hour

for interest and depreciation of plant. We have also to count something for attendance, and this cannot be reckoned at less than one farthing per hour per lamp. Adding these sums, we have

3·19d. per hour for gas.
0·39d. ,, ,, interest, &c.
0·25d. ,, ,, attendance.

Total cost, 3·83d. per hour.

And this with by far the most economical method yet devised for burning gas.

I understand that the Brush Company of Scotland are willing to lay down all the necessary plant, including steam boiler, engine, dynamo, leads, pumps, &c., complete, and guarantee their proper working, paying all expenses, including, carbons, &c., for a system of 40 arc lamps, to any person or combination of persons within reasonable distance of each other, and charge them only 3d. per hour per lamp during every 3,650 hours of lighting per annum. This is a straightforward and practical way of putting it; and should the lights be required for a proportionately less time per annum than the 3,650 hours, they will be able to tell you the small fractional extra expense per hour which it will cost.

Since the meeting I have been informed by Messrs. Bray and Co. that the price per hour for each of their 500 candle-power gas lanterns burning in Glasgow, at full power, for 2,000 hours per annum, would be 4·375 pence. This estimate includes erection, interest, and maintenance of plant in good working order. If, however, their double service system be adopted—that is, lowering the lamps at midnight to one jet of 30 candles (or 1,000 hours at 500 candles, and 1,000 at 30)—the price is reduced to 2·875 pence per hour per lamp. The above does not include lamplighters' wages, which we may reckon at one farthing per hour per lamp.

THE ELECTROLYTIC BALANCE OF CHEMICAL CORROSION.*

This paper treats of some fundamental points in silver electro-plating, and shows how a large amount of the electric power may be wasted by the use of too large a proportion of free potassic cyanide in the plating solution, or by using the liquid in a heated state.

In it is also described a method of ascertaining the degree of energy of chemical corrosion of metals in electrolytes, by means of the strength of electric current per unit of surface necessary to prevent such corrosion; the metals and liquids employed for the purpose in the present research being silver, and solutions of argento cyanide of potassium containing free potassic cyanide. Numerous examples, chiefly in the form of tables, are given of the strength of current required to enter cathodes of a given amount of surface, in order to exactly balance the chemical corrosive effect upon them at atmospheric temperatures, and at higher ones, of solutions of potassic cyanide of various degrees of strength.

The method employed was to take a given solution of cyanide of potassium, pass through it, by means of a sheet of platinum anode and a burnished sheet of silver cathode, a weak electric current, and add gradually to the liquid (with stirring) small portions of argento potassic cyanide, until the faintest perceptible deposit of silver occurred. The verge of deposition thus attained was called "the balance point;" and the conditions which determine and influence it, constitute the subject of this research.

* Abstract of a paper by G. Gore, LL.D., F.R.S., read before the Birmingham Philosophical Society.

The effect of various conditions upon the point of balance of electric and chemical energy were investigated, and the experiments are described. The influences examined were: Composition of the liquid, strength of current, size of cathode and density of current, electromotive force, temperature, ordinary chemical corrosion, nature of the cathode, &c. The circumstances were also investigated which affect the measurement of the current by the method employed in this research, viz., by depositing silver from a solution of argento potassic cyanide; and the sources of error (and their limit), in that method, are pointed out. The effect of varying the proportions of free potassic cyanide, and of argento potassic cyanide, upon the strength of current at the balance point, are shown in tables of results. The strengths of current just sufficient to prevent all corrosion and to deposit the whole of the silver from a solution of argento potassic cyanide of given composition and containing free cyanide are also shown. The influence of varying the proportions both of argento potassic cyanide, and free cyanide of potassium, upon the transfer resistance* of the solution, and thereby upon the balance point, are also investigated and the results described.

A number of results and conclusions were arrived at, some of which are as follows:—Variation either of the number of battery elements, the proportion of water, of free potassic cyanide, or of argento potassic cyanide, destroys the balance. The effect of altering the proportion of water is opposite with strong solutions to what it is with weak ones. The electric current at the point of balance appears to be entirely conveyed by the free potassic cyanide, and does not divide itself between the two salts until the liquid contains a certain proportion of argentic salt. In strong solutions of potassic cyanide, decreasing the number of battery cells, necessitates more cyanide of silver to restore the balance. The alteration of the point of balance by alteration of proportion of free potassic cyanide cannot be much accounted for by alteration of corrosive power of the liquid. A current from ten Smee's elements is about sufficiently strong to prevent all corrosion of silver at 60 deg. F. in a solution of cyanide of potassium containing a mere trace of argento potassic cyanide. The addition of nitrate, chloride, iodide, or sulphate of potassium to the cyanide solution has but little effect upon the balance point. Variation of strength and of "density" of current affect greatly the point of balance. Greater "density" irrespective of strength of current usually increases the amount of silver deposited. Difference of electromotive force of current had no conspicuous effect in altering the balance point. Rise of temperature of the liquid acts in two opposite ways, it increases the corrosive action, and by diminishing conduction-resistance it increases the current, and as the latter effect is usually a little stronger than the former one, rise of temperature alters slightly the point of balance, and enables the current to produce a sparing deposit of silver. The ordinary chemical corrosion of silver in a solution of potassic cyanide without an electric current is increased slightly by partial immersion (through capillary corrosion), and greatly by rise of temperature; it is also slightly greater in a weak solution than in a strong one, with solutions of a certain range of strength; and it is distinctly increased by contact with platinum. In consequence of the latter circumstance, a platinum cathode requires a somewhat stronger current than a silver one to enable the point of balance to be attained. In a mixed solution of potassic and argento potassic cyanides, even the smallest proportion of the former salt conveys a portion of the current, and if the cathode is large or the current is sufficiently weak, the whole of it is conveyed by that salt, however much of the double salt is present. An error is thereby introduced when deposition of silver in such a liquid is used as a measure of current. But with a large amount of the double salt, a small amount of potassic cyanide, and a current sufficiently strong, the proportionate amount of error is small. During the act of deposition the cathode surface is not at all corroded, and any deficiency in the weight of deposit is not due to corrosion, but to a portion of the current being conveyed by other ingredients of the liquid than the argentic salt. A current which produces deposition of silver, prevents all corrosion of a silver cathode in the same liquid. The addition of free potassic cyanide to a solution of the double cyanide alters both the resistance and the balance point. The quantity of current diverted from the argentic salt in solution is directly proportional to the amount of free potassic cyanide present, but not always in the same ratio. The presence of a large proportion of free cyanide, together with the employment of a feeble current conduce to the passage of a large amount of current through the liquid without depositing silver; and a current of ·001057 ampere (which would deposit ·132 grain of silver in two hours) was hardly strong enough to prevent all corrosion or to deposit any silver from a solution composed of 37·5 grains of argento potassic cyanide and 112·5 grains of free cyanide of potassium in three ounces of water. Whilst also a current if sufficiently weak, may traverse a solution of potassic cyanide containing double cyanide, without any of the current decomposing the latter, it cannot traverse a solution of double salt containing free potassic cyanide without some of it traversing the cyanide of potassium. With a very dense current also, a portion of it enters the cathode without depositing silver, and evolves gas.

It requires a much stronger current to balance the corrosion in a hot solution of the two cyanides than in a cold one, and in an instance given, a rise of temperature from 60 to 120 deg. F. was attended by the passage of 21 per cent. increase of current without deposition of silver. Addition of free potassic cyanide to a weak solution of the double salt *at the balance point*, first decreases and then increases the current by altering the transfer resistance, probably at the cathode. An amount of current equal to ·14857 ampere, entering a surface of ⅛ths of a square inch, was found to be sufficiently strong to deposit nearly the whole of the silver from a solution at 60 deg. F. composed of 70·11 grains of free potassic cyanide, ·0297 grain of double cyanide, and three ounces of water, the liquid retaining dissolved a little less than that amount of silver at its balance point under those conditions. The strength of current *at the balance point* in a weak solution of potassic cyanide, varies inversely as the amount of silver salt added, and at about eight times the rate. A certain strength of current must enter a given surface of silver in a given liquid under stated conditions in order to prevent all corrosion and produce deposition. The addition of the double cyanide reduces the amount of current conveyed by the free potassic cyanide into the cathode *at the balance point*. Successive additions of double salt to a solution of potassic cyanide *not at the balance point*, first decreases and then increases the current by altering the transfer resistance; it alters the relation of the molecules of potassic cyanide to the cathode so as to diminish their power of transmitting current into

Digitized by Google

that surface without depositing silver. The greater the proportion of double salt present, the greater the tendency to the deposition of silver. Addition of potassic cyanide to a week solution of the double salt *not at the balance point*, first decreases and then increases the current by altering the transfer resistance at the cathode; in this respect it behaves like addition of the double salt to a weak solution of potassic cyanide. With cathodes of platinum, a solution of potassic cyanide offered less resistance to the current (*not at the balance point*) than one of the double cyanide, but with silver cathodes the reversed effect occurred.

The balance point is a case of equalisation of molecular influences, including ordinary chemical corrosion, density of current, nature of cathode, temperature, proportions of water, argento potassic cyanide, free potassic cyanide, and the soluble salts present as impurities, either of which, by being disturbed, alters all the others. All these influences also have separate numerical values. A rise of temperature of 60 deg. F. requires an increase of ·000976 ampere to restore the equipoise. The experiments illustrate the dynamics of electro-silver plating; and the method employed in the research is applicable to the detection and measurement of molecular influence in electrolytes. In consequence of the alteration of any one of the conditions having the effect of altering all the remainder, all the above conclusions are limited in their application and are only correct under the conditions given in the paper. The fundamental explanation underlying these conclusions is, that the phenomena are essentially molecular; and that the mere presence and admixture of the double cyanide alters the molecular arrangement of the free cyanide *not at the balance point*, in such a way as to enable the latter to transmit a greater quantity of current into a cathode of given size, notwithstanding its being more diluted by the other salt.

The phenomena of the "balance point" constitute an interesting example of molecular equilibrium, in which the balance point may be compared to a ball suspended by an elastic cord, and having attached to it, a number of other similar cords, each drawing it in a different direction, and all of them being kept in a state of tension. In such a case an alteration of the degree of strain of any one of the cords, changes that of all others, and alters the position of the ball.

The research has a practical bearing both upon the measurement of electric currents by means of deposition of silver from a cyanide solution, and upon the technical process of electro plating. In the former it shows how a large proportion, or even the whole of a current may pass without being measured, and how the error may be reduced to the smallest amount; and in the latter, how a similar waste of current may occur, and how to prevent it.

It is manifest from the foregoing research, that the electrolytic balance of chemical corrosion of cathodes in other depositing solutions, such as those of gold, copper, nickel, &c., might form an extensive subject of experimental investigation.

Appended Note.- It was constantly found that in using a non-corrodible anode, such as platinum, the amount of current passing was very much more easily regulated by varying the size of the anode than that of the cathode. With a corrodible anode, however, such as silver, this effect was not observed.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).

The nineteenth ordinary general meeting of the shareholders of this Company was held at the offices, Old Broad-street, on Tuesday last, under the presidency of Sir Daniel Gooch, Bart., M.P.

The SECRETARY (Mr. Edmund Dickens) read the notice convening the meeting and the minutes of the last meeting, which were approved by the present meeting and signed by the chairman as correct.

The report of the directors, an abstract of which has appeared in *The Electrician*, was taken as read.

The CHAIRMAN, in moving the resolution that the report be received and adopted, said: I think I may congratulate you upon the continued success of our Company. The accounts will show you that during the past year a net profit of £92,260 has been made, and after paying interest on debentures, and also the interim dividend which was paid in the middle of the year, there is a balance available for dividend now of £130,245. The 15 per cent., which is now proposed to be paid to you, will absorb all that but £63,015, which is carried forward to next account. The work we have done in the past year is pretty clearly set forth in the report, but I will refer to it shortly. You see by paragraph A that 550 miles of cable have been laid under a concession from the Austrian Government between Corfu and Trieste, and it now forms part of the Eastern Company's system. The German Union Company's cable was repaired in the North Sea between Lowestoft and Greetseil. That cable was repaired in the winter, and was a matter that caused a great deal of trouble through the bad weather which prevailed. However, the cable was properly repaired, and is now in efficient working condition. Paragraph C refers to the laying of the German Union Company's cable, between Valentia, in Ireland, and Greetseil, in Germany. That amounted to 776 miles, and that cable was completed in April. The shore ends of the cable were laid in the previous year. 254 miles of cable were manufactured for the Western and Brazilian Telegraph Company, and laid in April between Ceara and Maranham, on the Brazilian coast. The Brazilian Submarine Telegraph Company's cable, off Pernambuco was also repaired, when the ship was out in that neighbourhood. Between the months of May and September extensive repairs were effected in the Anglo-American Telegraph Company's French Atlantic cable between Brest and St. Pierre, in depths up to 2,000 fathoms, after a submergence of thirteen years. I am sure it must be gratifying to the shareholders of this Company to find that a cable after thirteen years immersion was repaired. The cable itself was in perfect condition except in the parts where injury had taken place. Its repair has given confidence in cable property when it is seen that it may be raised after so many years. The "life" of a cable has been thought to be ten years; but I think we may safely say that we do not know what its life is if we can pick it up and repair it as we have done in this case. Great credit is due to the officers of the Company who were engaged in that work, for it was a very difficult one to perform. They were occupied some time in doing it, but their efforts were successful. In the month of August the Eastern Telegraph Company's cable between Porthcurnow and Lisbon was repaired in a depth of 2,700 fathoms, and a cable for the same company (234 miles in length) was manufactured and laid between Malta and Tripoli in October. As to the cable after being five years down, the pieces I have seen brought up are just as clean as when it was laid. During the month of October the Brazilian Submarine Telegraph Company's cable between Lisbon and Madeira was duplicated, 663 miles of cable having been manufactured for this purpose; and the Lisbon shore end of the original cable was relaid. A cable 965 miles in length has been manufactured for the Eastern Extension Telegraph Company, which will be laid in the China Sea between Hong Kong and Shanghai. The steamship "Scotia" is now engaged in that work, and is out there. The next paragraph in the report refers to the condition of the works, which are in an excellent state of repair and efficiency. The steamship "Calabria" was engaged by the Government as a troopship during the Egyptian war, and she is now on her road to Egypt again for the Government. The works we have in hand at present are about 900 miles of cable for the Eastern Company for the Red Sea, and the Great Northern cable for the China Sea of 1,280 miles. Those practically are the facts connected with the work we have done. As to the accounts, I do not think I can go through them in a useful way, but I should be very glad to answer any questions respecting them; or with regard to any other matter. I now move:—"That the report and accounts of the directors to the 31st December, 1882, submitted to this meeting, be, and the same are hereby received and adopted, and that a dividend of 36s. per share (in addition to the 12s. per share interest on interim dividend paid to June 30th, 1882) be paid upon all shares of the Company for the year ending December 31st, 1882, and that such dividend be paid free of income-tax."

Sir THOMAS FAIRBAIRN, Bart.: I have great pleasure in seconding that.

Mr. JOHN NEWTON said he was glad to hear the chairman give the weight of his high authority in telegraph matters in saying that the life of a cable was more than ten years. He had heard a contrary opinion expressed some time since by a person who was not so high an authority as Sir Daniel Gooch. It might now be taken as definite that the life of a cable was considerably more than ten years, if a cable laid down thirteen years ago could be brought from the bottom of the sea at a depth of 2,700 fathoms, the cable being found in sound condition. If that was the condition of a cable made and laid thirteen years ago he should like to know whether, as the cables that were manufactured now were of superior quality, there was not a greater probability that they would live longer even than those that were now thirteen years old, and were doing such good work. He thought that the holders of submarine cable property were sometimes doubtful as to their property being one that could be relied on; but the more that idea was dispelled the better for this Company and the other companies for which they worked.

The CHAIRMAN: There cannot be a doubt that the cables now made have all the experience of the last thirteen years, and we have every reason—we are certain, in fact, that those that are now made will last longer than those which were originally made. Where there is any risk of the teredo they are now protected by a coating of brass ribbon round the core, and the cables are all now protected by a composition which, we believe, will protect the hemp from decaying, and the salt water from getting to the iron wire. There is every reason to believe that cables now made will last longer than those which were originally manufactured. He then put the motion in the usual way, and it was carried unanimously. Continuing, he said: The next motion is the re-election of the directors, and I now move "That Lord Alfred Paget be and is hereby elected a director of the Company."

Mr. PHILIP RAWSON seconded the motion, which was carried unanimously.

The CHAIRMAN: I have now to move "That Mr. George William Campbell be re-elected a director of the Company."

Sir THOMAS FAIRBAIRN seconded the motion, which was carried.

The CHAIRMAN: The next motion is the election of the auditors, which is moved by the shareholders themselves.

Mr. GIBSON said that he had not the pleasure of knowing the auditors himself. He must, therefore, leave it to those around him, to whom probably those gentlemen were known. He then moved separately the re-election of Mr. John Gane and Mr. James Glegg at a remuneration of £150 each.

Both resolutions were carried.

The CHAIRMAN: That concludes the business of the general meeting. We now come to the business of the special meeting for the purpose of confirming the resolution you came to the other day. I will ask Mr. Burt to read it.

The SOLICITOR (Mr. Burt): The resolution which the chairman proposes is "That the following resolution, passed at the extraordinary general meeting of the Company held on the 6th February, 1883, namely: 'Resolved that the Bill now pending in Parliament, intituled "A Bill for removing doubts as to and for extending the powers of the Telegraph Construction and Maintenance Company (Limited), and for other purposes" be and is hereby approved subject to such additions, alterations, and variations, if any, as Parliament may think fit to make therein,' be and the same is hereby confirmed." It is needful by law that there should be two meetings, one to pass and the other to confirm the resolution, and the chairman now proposes that the resolution be confirmed.

Sir THOMAS FAIRBAIRN seconded the motion.

The CHAIRMAN put it to the meeting, and declared it carried, adding that that concluded the business of the meeting.

Mr. NEWTON moved a vote of thanks to the chairman, and expressed his regret at not hearing anything about the electric light business.

The CHAIRMAN: You should have come to the last meeting.

Mr. NEWTON replied that he thought the first was a formal meeting, and, therefore, he did not attend. He thought that the present would be the more important meeting. There had been great excitement about electric lighting, but he did not suppose in their property they would see, as had been seen in other cases, their shares, say, at 400 per cent. premium, and then 50 per cent. discount. He was very glad to see their shares had been very little affected by the proposal of the directors of the Company to engage in electric lighting business. They had done their work so well as sub-

Digitized by Google

marine cable makers that no one else, he said, could touch them. If they were going to have something of the same sort with regard to electric business, then their shares must go up. He would, however, like to know if the shareholders would have an opportunity of inspecting it at the Crystal Palace or anywhere else, so that they might see something of the character of the light which was under the control of the Company.

A SHAREHOLDER seconded the motion.

The CHAIRMAN: I did not explain more in detail the Bill before Parliament, because I thought it was fully explained at the last meeting. The object of that Bill is to obtain powers which we have not got now, that is, powers to use electricity in every direction for which electricity is available. Our present power is limited to telegraphy, and we are seeking powers to carry out electric lighting arrangements in the same way with the appliances we have got, which we believe we can do to the interests of the shareholders. As to exactly what we are going to do, I think you must wait till we get the Bill. I think we shall get a fair share of electric lighting business throughout the country, but until we get the power we cannot say what we can do. I hope we shall be as successful as we have been in the past, and we shall do our best.

The meeting then separated.

TO THE SHAREHOLDERS OF THE

UNITED TELEPHONE COMPANY (Limited).

36, Coleman-street, London, E.C., 28th February, 1883.

Dear Sir,—The Board of Directors, in their circular of the 24th of May last, gave to the shareholders a short history of the result of the litigation which had taken place up to that date on the Company's Patents. In Scotland the Company had obtained judgment in its favour, both on Edison's Patent for the Carbon Transmitter and on Bell's Patent for the Magneto Telephone. In England a similar decision had been obtained in favour of the Company under Bell's Patent, but a technical objection to the validity of Edison's Patent had been upheld by Mr. Justice Fry, and under these circumstances, although the Hunning's Transmitter manufactured and sold by the defendants was held to be within Edison's specification, an injunction was refused.

The Directors, on a careful consideration of the circumstances of the case, came to the conclusion that an immediate application for a "disclaimer" was desirable. Although they had good reason to hope that Mr. Justice Fry's decision on this technical point would not be sustained by the Court of Appeal, they did not forget that during the whole time the appeal was pending an adverse decision would be standing against them, and that during that time they would be unable to restrain the manufacture and sale of infringing instruments; whereas an application for a disclaimer, if promptly made, would be heard before the long vacation, and, the blot upon the patent once cured, Mr. Justice Fry's decision would stand in all points in favour of the Company. The necessary petition for leave to "disclaim" was therefore at once lodged, and on the 29th of July the application was granted by the Attorney-General, and the necessary "disclaimer" was filed on the 16th of August.

By the terms of the Attorney-General's fiat protection was given to transmitters manufactured prior to the 29th of July by certain persons who opposed the application, but the number of instruments so protected is not large. Protection was also given to contracts bonâ fide entered into by the opponents for the manufacture of transmitters before the 29th of July, and under this proviso an attempt is being made to claim protection for a large number of instruments for the manufacture of which verbal contracts are stated to have been made. The Directors question the bonâ fides of these alleged contracts, and they have taken the necessary steps to have the point determined by the Attorney-General.

The disclaimer having been filed, the Directors withdrew their appeal from Mr. Justice Fry's decision. Upon the patent as disclaimed the decision was entirely in the Company's favour, and no reason, therefore, existed for bringing it under the review of the Court of Appeal. Proceedings have since been taken under the patent as amended against several persons infringing the patent, and in every case the defendants have submitted to judgment and paid the costs of the proceedings.

Messrs. Harrison, Cox-Walker, and Co., against whom an injunction was granted for infringement of the Bell Patent in May last, lodged an appeal against this decision, which came on for hearing on the 28th of January last, before the Master of the Rolls, Lord Justice Lindley, and Lord Justice Bowen. After a most patient hearing, extending over nine days (nearly seven of which were occupied by the appellants), the court gave an unanimous decision in favour of the Company, upholding Mr. Justice Fry's decision, and dismissing the appeal with costs.

There remains, of course, the possibility of an appeal to the House of Lords, but, even should such an appeal be made, the Directors feel great confidence that a patent which has been unsuccessfully attacked on three different occasions, which has been under consideration by the courts for thirty-three days, and which has been supported by the decisions of two judges of first instance and of three judges of appeal, is not likely to be broken down if brought before the ultimate Court of Appeal.

The Company has obtained injunctions against the following persons and firms for infringing one or more of its patents:—

Alexander Maclean of Edinburgh.	Cox and Williamson of Plymouth.
M. Theiler and Sons of London.	Edwin Butler of Liverpool.
Harrison, Cox-Walker, and Co., of Darlington.	W. Haines of Birmingham.
Orme and Co. of London.	F. Hebden and Co. of Bradford.
	H. and E. J. Dale of London.

In other cases apologies have been accepted, accompanied by undertakings to discontinue the manufacture or sale of infringing instruments.

The Directors, while congratulating the shareholders upon the successful manner in which their patents have been upheld both in England and Scotland, think the present a favourable opportunity to give a few figures illustrative of the progress of the Company.

The number of exchange subscribers to the London system was:—On 28th of February, 1881, 845; on 28th of February, 1882, 1,505; on 28th of February, 1883, 2,541; showing an increase of 660 subscribers for the year between February 28th, 1881, and February 28th, 1882, and of 1,036 subscribers for the corresponding period between 1882 and 1883.

The gross income from London rentals alone has now reached £60,000 per annum, and the annual value of the unexecuted orders in hand—which will be added day by day to the revenue of the Company as the lines are completed—is to-day about £5,000. The Company is receiving on an average orders each day of the annual value of about £100.

As showing the use made of the Company's exchange system in London, the calls of the subscribers on five days in the third week in February (omitting Saturdays and Sundays) for the past three years were as under:—

1881	Feb. 15..... 4,195 calls Feb. 16..... 3,986 calls Feb. 17..... 4,361 calls Feb. 18..... 4,838 calls Feb. 21..... 4,576 calls	Total for the five days ..... 22,256 being a daily average of ... 4,451 or 5·13 per subscriber.
1882	Feb. 15..... 9,576 calls Feb. 16..... 9,770 calls Feb. 17..... 9,662 calls Feb. 20..... 9,790 calls Feb. 21..... 9,788 calls	Total for the five days ..... 48,586 being a daily average of ... 9,717 or 6·57 per subscriber.
1883	Feb. 15..... 19,089 calls Feb. 16..... 20,042 calls Feb. 19..... 18,874 calls Feb. 20..... 18,501 calls Feb. 21..... 18,602 calls	Total for the five days ..... 95,108 being a daily average of ... 19,021 or 7·59 per subscriber.

Each call implies an answer, and consequently the number of calls doubled will represent the minimum number of messages daily transmitted along the Company's wires.

The Directors are availing themselves of every opportunity of extending their business in the provinces by enlisting local interest in the formation of subsidiary companies—one for the western counties and another for the South of England and Brighton being in course of formation—in addition to those already established, in which, as the shareholders are aware, the Company has now so large and progressive an interest, both in shares and royalties.

In conclusion, the Directors would urge each shareholder to supplement the exertions of the board by using his personal influence among his friends to bring subscribers to the Company's system.—Yours faithfully,

JAMES BRAND, Chairman.

INSULATED ELECTRICAL WIRE, Silk, Cotton, or India-rubber covered. Conductivity guaranteed. German Silver Wires for Resistance. Braided Handle Cord, Silk Cord for Electric Bells, &c.—WILLIAM RICKARD, Derby London Agent (stock kept), EDWIN HOLLOWAY, 2, Gutter-lane, E.C.

RECENT INVENTIONS.

ABSTRACT OF SPECIFICATIONS.

2823. GENERATING AND STORING ELECTRIC ENERGY, &c., *C. Westphal, Berlin.*—*15th June*, 1882. 8*d*.

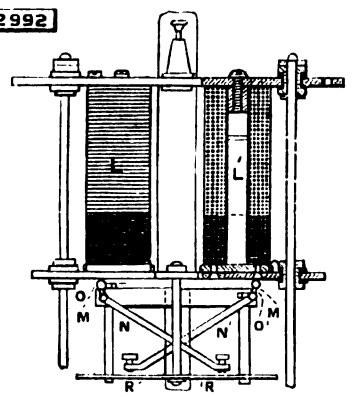
The object of this invention is to produce electric currents from the gaseous compounds of coal, and so avoid the roundabout method of producing them by means of a steam engine and dynamo machine. The principle of the invention consists in producing a constant current of electricity by means of water gas or generator gas and oxygen—that is to say, by using these gases for artificially producing on plates the state assumed by electrodes during the electrolytical decomposition of water, which state is the cause of the production of polarisation currents. The patent describes the apparatus employed by the inventor to accomplish his object.

3010. IMPROVEMENTS IN ELECTRIC LAMPS WITH INCANDESCENT CONDUCTORS, *W. E. Debenham, London.*—*26th June*, 1882. 4*d*.

To obviate the evil caused by the unequal expansion of the glass and platinum conductors of incandescent lamps, the inventor takes two samples of glass, one having a higher the other a lower coefficiency of expansion than the platinum, and mixes these two samples together, to render the resultant as near as possible of the same coefficiency of expansion as the platinum. The carbons he makes of sewing cotton soaked in a solution of gluten dissolved in alcohol. Other improvements are described.

2992. REGULATING THE ACTION OF ELECTRIC ARC LAMPS, *W. R. Lake, London.*—*23rd June*, 1882.—(*A communication from J. M. A. Gérard Lescuyer, Paris.*) 8*d*.

The illustration shows the method of regulation adopted. The action of the apparatus is as follows:—The carbons being in contact, the current circulates around cores L L^1, and draws them up. In rising they lift cross-bar M, which by means of small links O O^1 causes the pieces N N^1 to clamp the upper carbon holder and lift it, thus striking the arc. When the length and resistance of the arc increase more of the current begins to travere the fine wire coil at the bottom of the electro-magnet, and this flows in a reverse direction to that through the thick or upper coil. Consequently, L L^1 are demagnetised, and N N^1 descend until they come into contact with disc R, when they release the carbon holder.

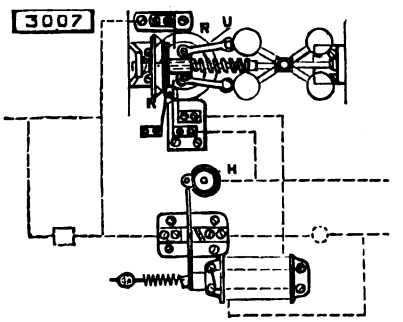


2990. APPARATUS OR MACHINERY FOR GENERATING, CONTROLLING, AND UTILISING ELECTRIC CURRENTS, *J. H. Johnson, Lincoln's Inn-fields.*—*23rd June*, 1882.—(*A communication from La Compagnie Electrique, Paris.*) 6*d*.

This relates, first, to improvements in dynamo machines, having Gramme ring armatures and electro-magnets provided with multiple armatures which completely surround the apparatus, so as to render them fit for use as generators and motors for the transmission of power; secondly, to the regulation of the speed of the motors in this respect. The inventor claims "the combination of electric generators of feeble residual magnetism sending a current to motors possessing great residual magnetism, and their application to electrical purposes as described."

3007. MACHINERY FOR THE REGULATION OF SPEED IN MACHINERY DRIVEN BY ELECTRICITY, &c., *Fleeming Jenkin, Edinburgh.*—*24th June*, 1883. 6*d*.

The invention is illustrated in the accompanying engraving, which represents an arrangement of governor and governing relay. Suppose the speed of the machine to which the current is being transmitted exceeds the limit, spring V has been so adjusted that slider U will bring springs 2 and 3 into contact, pressing them together by spring 1, which is insulated from the other two. Spring



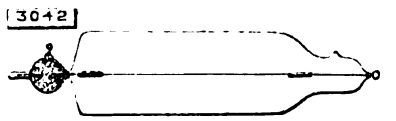
2 is connected by wire with terminal H, and therefore a current instantly traverses the other wires exciting the core of electro-magnet. The resistance of the electro-magnet coils is such that only a suitable portion of the main current is diverted through the magnet. The armature and lever are instantly pulled over, breaking the current through the machine and making contact. Part of the current is now flowing through to the frame, and part through the resistance coil to frame. If the speed of the machine should be such as to bring the slider of the governor into contact with spring 4, the circuit of the receiver will be closed.

3108. SECONDARY BATTERIES OR MAGAZINES OF ELECTRICITY, &c., *H. J. Haddan, Kensington.*—*1st July*, 1882.—(*A communication from C. F. Brush, Cleveland, Ohio, U.S.*) 2*s*. 4*d*.

To form the plates the inventor takes two ordinary lead plates in dilute sulphuric acid, and charges them in such a manner that a coating of peroxide of lead of sufficient thickness is formed on both of them; these plates are then associated together in the usual manner, and charged so that one of the plates remains uncharged, and constitutes the oxygen element of the battery, while the other has its charge reversed, and constitutes the hydrogen element. According to another part of this invention, the plates before the process of forming are coated electrolytically with a deposit of coherent lead. With grooved plates the inventor employs special means to make the deposit of coherent lead thick in the grooves. Another part relates to the covering of plates with porous metal, reduced from oxides by reducing gases. Another part relates to the construction of plates of masses of finely-pulverised metallic lead and lead oxide in an intimately mixed condition, pressed hydraulically together into a compact mass. Other methods of forming plates are also described, as well as methods for charging batteries.

3042. INCANDESCENT ELECTRIC LAMPS, *F. L. Willard, London.*—*28th June*, 1882. 6*d*.

The invention relates to a method of avoiding fracture of the filaments of incandescent lamps through being rigidly connected to the leading-in wires, and so allow for a certain amount of con-



traction and expansion. To accomplish this the inventor inserts the platinum wires into the two ends of a cylindrical glass bulb, as shown in the figure, in which he places the filament. This bulb has at its base a small bulb containing mercury. The filament is made from a species of veneer called "white lines," carbonised. One end of it is cemented with a mixture of coal-tar and coke-dust to one leading-in wire, and the other end to another piece of platinum wire which dips into the mercury, the other leading-in wire being fused into the small end of the bulb and in contact with the mercury.

3047. TELEPHONIC RECEIVERS, *W. Spence, Chancery-lane.*—*28th June*, 1882.—(*A communication from M. Kotyra, Paris.*) 6*d*.

The chief peculiarity in this invention is the construction of the compound magnet and the soft iron armature. The magnets are composed of multiple bars separately magnetised and solidly bound together. The polar extremities carry the soft iron cases of the bobbins, and the whole forms a magnet which is a sort of interrupted frame.

3101. AN IMPROVED ARC ELECTRIC LAMP, *R. H. Courtenay, Southampton-buildings.*—*30th June*, 1882. 6*d*.

This relates to a peculiar gripping arrangement for regulating the carbons. One or more solenoids are so arranged that each shall draw up cores, which lift a small slotted plate, the sides of the slots being of a taper or wedge shape. In each of the slots are placed movable blocks, which grip the upper carbon when the current energises the solenoids, thus lifting the rod and striking the arc. The blocks are retained in position by springs.

3036. DYNAMO-ELECTRIC MACHINES, *W. E. Ayrton, F.R.S., and J. Perry, Finsbury.*—*27th June*, 1882. 6*d*.

The first part of the invention consists in the use of field magnets made of steel and iron combined; either a steel tube enclosing an iron core, or *vice versâ*, or alternate plates of the two metals. The inventors find that with this arrangement a dynamo will behave like a combination magneto and dynamo machine, and that great constancy is the result. The second part relates to the winding of any ring armature. The ring is made of two pieces joined together, so that the screws are flush with the ordinary surfaces of the ring. The coils are slipped on these halves, and between every two is also slipped a ring of wrought iron, out of which a small portion is cut at one place, so that the ring is incomplete, as shown in the

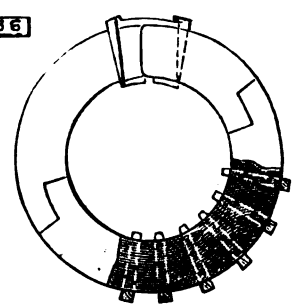


figure. This is to prevent induction currents. Other parts of the invention relate to a method of connecting up when any even number of pairs of field magnets are used near the armature, and to the use of an armature core of phosphor bronze, or brass, or steel, with a great many rivets of soft iron passing through it.

3128. ELECTRIC LOGS OR APPARATUS FOR ASCERTAINING THE SPEED OF SHIPS, &c., *R. M. Lowne, Finchley.*—*3rd July*, 1882. 6*d*.

The inventor employs a rotator similar to an ordinary mechanical ship's log, the cable attached to which contains two insulated wires, which are connected respectively to a recording apparatus on the ship and to the rotator under water. The rotator is made to make and break an electrical circuit at every given number of revolutions so as to operate the recording apparatus on board ship, and thereby record the number of revolutions of the rotator. The inventor claims the machinery required to carry out the invention, and also novel methods of establishing connection between the battery poles and the rotator.

3231. ELECTRICAL CONDUCTORS, *F. Jacob, Westminster.*—*11th July*, 1882. 6*d*.

This relates to Patent No. 231 (17th Jan., 1882), granted to C. W. Siemens, and communicated to him by the present inventor. That patent related to "improvements in telephonic conductors" only, and the object of this patent is to claim the invention there described as applied to electric conductors generally, whether employed for telegraph, electric light, or other purposes. The invention consists in a method of connecting several sets of electrical instruments by employing the double conductors of one set as a single conductor for another set, and multiples of such double lines as single lines.

Digitized by Google

SLIP

PARA.—The cable between Maranham and Para is now repaired.

THE CHANNEL ISLANDS.—Telegraphic communication between Guernsey and Alderney is again restored.

POSTMASTER-GENERAL.—Mr. Fawcett has resumed his official duties, and was present in the House of Commons on Monday last.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 2nd inst. amounted to £4,406.

POST OFFICE TELEGRAPHS.—Mr. B. Murphy, sorting clerk and telegraphist at Londonderry, has been appointed postmaster of Curragh Camp.

SIGNS OF THE TIMES.—"Electric light fittings are also becoming an important staple with one or two leading firms."—*Times'* Birmingham Trade Report.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated earnings of this company for February were £1,544, against £2,109 in the corresponding period of last year.

BOOKS RECEIVED.—"Sopra un modo d'Interpretare i Fenomeni Elettrostatici Saggio Sulla Teoria del Potenziale." di G. B. Ermacora. (Padova: A. Draghi, publisher. 1882.)

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of February, 1883, amounted to £46,667, and to £44,046 in the corresponding period of 1882.

ELECTRIC LIGHTING FOR BEDFORD.—The Bedford Local Authority have applied to the Board of Trade for a license to supply electricity for public and private purposes in the borough.

ELECTRICAL TRANSMISSION OF POWER.—On Thursday next, Dr. C. W. Siemens, F.R.S., will lecture at the Institution of Civil Engineers, on "The Electrical Transmission and Storage of Power."

NATIONAL TELEPHONE COMPANY.—At a meeting of the directors of this company, held on the 1st March, it was resolved to pay 6 per cent. preference dividend for the six months ending 31st December last, less income-tax.

EASTERN EXTENSION AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of February, 1883, amounted to £29,391, and to £27,473 for the corresponding period of 1882, being an increase of £1,918.

SAFETY LAMP FOR MINERS.—It is stated that hundreds of communications have been received by Mr. Burt, M.P., on the subject of an electric miners' safety lamp, for which £500 has been offered by Mr. Lever, as announced recently in our columns.

THE AUSTRALIAN CABLES.—Communication with Australia was interrupted on Tuesday by the breaking of both Port Darwin cables. Both lines were, however, repaired by Wednesday afternoon. The break occurred about 100 miles from Banjoewanjie.

MESSRS. DENNIS AND CO.—We are informed that Messrs. W. F. Dennis and Co., of 101, Leadenhall-street, E.C., sole agents for Messrs. Felten and Guilleaume, wire drawers, &c., of Mülheim-on-Rhine, have opened a branch office at 3, Tower-chambers, Water-street, Liverpool.

DUPLICATION OF THE HONG KONG-SHANGHAI CABLE.—The laying of the duplicate cable from Hong Kong to Shanghai will probably be completed this week. It has been manufactured by the Telegraph Construction and Maintenance Company for the Eastern Extension Telegraph Company.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company for February, 1883, were £17,800. For the period from 1st January to 28th February, 1883, they were £36,040, against £34,360 for the corresponding months of 1882, and £34,408 for the same period of 1881.

ELECTRIC LIGHTING IN THEATRES.—Mr. J. E. Jackson, manager of the Electric Carbon, Storage, &c., Company, Leith, has received instructions to light up the Theatre Royal, Edinburgh, throughout. Accumulators will be used to a great extent. This is the third theatre the company has lighted.

ROYAL SOCIETY.—The paper which was to be read before this Society on Thursday last was entitled "Notes on the Absorption of Ultra-Violet Rays by Various Substances. Notes on the Reversal of Hydrogen Lines; and on the Outburst of Hydrogen Lines when Water is Dropped into the Arc. Note on the Order of Reversibility of the Lithium Lines." By Professors Liveing and Dewar.

THE EDISON SYSTEM IN SCOTLAND.—On the evening of Friday, March the 2nd, the Scottish branch of the Edison Electric Light Company gave an exhibition of their system in the rooms which they have just opened at 104, West George-street, Glasgow, with Mr. C. T. Grant as manager. One of the principal features of the exhibition was a three-hundred candle lamp, which was only two feet six inches high and fifteen inches in diameter.

A LAMP FOR COLLIERIES.—M. G. Mangin has invented a miners' lamp, in which a Swan incandescent lamp, supplied by a Faure accumulator, is enclosed in a casing of water, which serves for two purposes. It increases the illuminating power; and, if the lamp should break, the incandescent carbon would be at once extinguished. The glass casing, with the conductors covered with lead, is, in turn, enclosed in a copper case, silvered inside, and provided with strong converging sides, which throw a bright light.

ACCIDENT TO A TELEGRAPH STEAMER.—As the new steamer, "Viking," built by Messrs. Pearce Brothers for the Western and Brazilian Telegraph Company, London, was entering the tidal harbour at Dundee, on Friday, the 2nd instant, the weather at the time being foggy, she ran up against the west quay head, doing considerable damage to the woodwork below water mark. The steamer's stem was much twisted, and it is expected that she will require to be docked before any real estimate of the damage can be ascertained.

TENDERS WANTED FOR A TELEGRAPH LINE.—As no satisfactory tenders have been received for the erection of a telegraph line in the Orange Free State, South Africa, fresh tenders have been invited by the Government of that State. These tenders are to be sent in by the 5th May next. The length of line will probably amount to 286 miles. Specifications can be seen at the offices of the different Free State Consuls in London; also at Berlin and Hamburg, in Germany; at Arnhem, in Holland; at Brussels, in Belgium; and at Paris.

THE EASTERN EXTENSION COMPANY'S SYSTEM.—We understand that an important link in this system is shortly to be carried out by arrangement between the Siamese Government and the Eastern Extension Company. The extension will consist partly of cable and partly of land line, and when complete will form a duplicate route from China, &c., to Singapore. The new route will consist of a cable from Penang to Quedah, then a land line across the Malay peninsula to Singora, on the Gulf of Siam. From Singora a cable

Digitized by Google

will be laid across the Gulf to Bangkok. The French will connect Bangkok with Saigon by a land line across the Cambojian peninsula, thus completing the link.

THE RATING OF TELEGRAPH WIRES.—A question of some interest to telegraph companies was discussed at a recent meeting of the Helston Board of Guardians. This was the rating of telegraph wires. It appears that the Direct Spanish Telegraph Company have a few miles of underground wire running through this part of Cornwall, and that hitherto the overseers have neglected to rate the company for their line. The gentleman on the board representing the assessment committee stated that this neglect arose from the fact that the committee were awaiting the issue of an appeal against the rating of wires, in order to act in accordance with the decision, and to be able to fix on some definite assessable value. Another member stated that the present company did not object to the rate being made, but to the amount. Eventually it was agreed between the company's representative and the board that £2 per mile would be a fair sum.

COMMUNICATION WITH LIGHTHOUSES.—In the House of Commons on Friday week, in answer to Mr. Vivian, who wanted to know whether "there was any immediate prospect of the Trinity Board taking into their favourable consideration the question of establishing communication between outlying lighthouses and the shore by means of electric cables," Mr. Chamberlain stated that "This subject had received for a long time the attention of the Trinity Board and of the Board of Trade. He was not quite certain that the results to be obtained by such a communication as was suggested would justify the very large expenditure which would have to be incurred. At the same time, he was anxious that the experiment should be made. He had learnt some time ago that the Telegraph Construction and Maintenance Company were willing to try an experiment for twelve months at their own risk and cost. He had sanctioned the experiment with the proviso that, if successful, the Trinity House would be allowed to purchase the cable and apparatus for £3,730. He thought it best, however, that the determination of the undertaking should be left to Sir James Douglas, the engineer of the Trinity House Corporation. The Telegraph Company had rejected that condition, so that for the moment the negotiations had come to an end."

BICHROMATE BATTERIES.—M. Luigi Ponci, director of the Technical Institute at Coma, thus describes a new bichromate battery made by him. It is composed of one kilogram of bichromate of potash, four litres of water, and two litres of chlorhydric acid. The bichromate is crushed and dissolved in boiling water. After being completely dissolved, the whole of the acid is added to it. In this way a liquid is obtained containing a mixture of chloride of potassium and bichromate of potash. The use of this liquid prevents the formation of crystals in the battery. The battery is contained in a wooden case, lined inside with lead, and holding six glass jars of rectangular form, the bottoms of which are pierced. These jars rest in the case on sheets of glass, which allow the liquid to circulate. The case is furnished with a leaden syphon tube, with which the battery can be charged and discharged. The elements are composed of a sheet of zinc and two plates of carbon. The two poles thus obtained are insulated from one another by a small band of india rubber, and compressed into a solid block. A case of six cells will give a current of the same intensity as six Bunsen cells, small size, for two hours. With three cases an Edison eight candle lamp of small resistance can be kept alight, and with eight cases a good arc light can be maintained.

"THE ELECTRICIAN" SUPPLEMENT, No. 2.—With our last issue we published No. 2 of our series of proposed supplements. It consisted of a table, giving the relation between the resistance and weight of electric lighting leads of various diameters—single wire, 7-strand, and 19-strand—with the amount of current which can be safely carried thereby, and other data. Owing to an oversight, the heading of the second column from the right hand side of the table was printed "Per minute," instead of "Per 100 yards." The mistake is so obvious, that, doubtless, many of our readers have already made the necessary correction. Also, for the conductivity given in footnote (*a*) read $R = \frac{\cdot 003265}{d^2}$ instead of $\frac{1003265}{d^2}$. We have received many kindly criticisms, some of which we publish in our correspondence, and, judging from the tone of the letters, we hope that we have succeeded in supplying something that will be of practical utility. It must be remembered, however, that any figures relating to electric light leads must necessarily be purely tentative, having regard to the present position of the industry they relate to. As time goes on, however, "tentative" will give place to "perfected," and we shall not be slow to make our readers acquainted with the fact. In the meantime we shall be glad of suggestions and criticisms, which will receive due consideration at our hands. Supplement No. 3 is in course of preparation, and we hope that its publication will not be so long delayed as was that of Supplement No. 2. We may add that the latter will not at present be issued apart from the number of *The Electrician* containing it, as we hope that further information and criticism may enable us to greatly improve the table.

PNEUMATIC TUBES AND ELECTRICITY.—A good illustration of how time can be saved by the aid of pneumatic tubes and electricity is afforded by the following extract from a recent issue of the *Northern Echo*, of Darlington:—"The telegraphic messages received daily in Darlington Post Office from all parts of the world have, for some time past, been delivered to the *Northern Echo* office direct by means of a pneumatic tube. This apparatus has dispensed with the necessity of telegraph boys travelling to and fro at all hours of the night between the telegraph and *Echo* offices. Messrs. Cox-Walker and Co., of Darlington, the eminent telegraph engineers, have now completed a most important improvement in this clever and ingenious apparatus, of which they were the original constructors. Heretofore telegraphic signals have been exchanged between the Post Office and the sub-editor's room, announcing the despatch and arrival of messages. To work the signals it was necessary for an operator at either end to touch a spring button, setting the electric current in motion. By the alteration now brought into working order this necessity is dispensed with. Messages are sent through the tube without preliminary notice immediately on their arrival, and, by a new automatic arrangement, each message, on its arrival in the *Echo* office, reports back to the Post Office by telegraph its own delivery. In less than twelve seconds about three times as much written matter as is contained in this paragraph is conveyed from the telegraphist to the sub-editor, and the fact of its safe delivery acknowledged back in the Post Office."

POST OFFICE CIRCUMLOCUTION.—Under this head, Mr. Henry Chapman, of 113, Victoria-street, S.W., writes to the *Standard* of the 2nd inst. as follows:—"On the night of

Digitized by Google

Tuesday, the 18th July last, I received from the Post Office what purported to be a telegram from Spain, but, on opening it, I found that the message had been entirely left out, and the name of the sender—itself misspelt—alone appeared on the form. Early on the following morning (Wednesday) I applied at the Post Office for an explanation, and was told that the only way to find out if there was any mistake was to have the message repeated; but to do this I should have to make a deposit of eight shillings and sixpence, which would be immediately refunded if it were found that an error had been made in transmission. I paid the deposit, and waited in vain all day for the repetition of the telegram. During the morning of the next day, however (Thursday), it was brought to me, not quite correct yet, but still intelligible, as this time it contained the message itself. I thereupon wrote to the Secretary of the General Post Office, stating the case to him, and received a reply that the matter was being looked into. Not hearing further I wrote to him again on the 25th August, asking to have the eight shillings and sixpence refunded, and received a reply, dated 30th August, stating that the matter was still being investigated. On October the 19th I again wrote to the secretary, recapitulating the facts, and asking for the deposit to be refunded, and on the 24th October I received a similar letter to the previous one. On November 30th I again asked to have the eight shillings and sixpence returned, and received a reply that 'the matter shall receive attention.' On December 9th I again wrote and got a similar answer, and, being apparently no nearer to a solution than when I wrote the first letter, I wrote again to the secretary on the 13th ultimo, and have received the following answer:—'In reply to your letter of the 13th instant, I beg leave to inform you that it is the practice of the department to retain the forms of European foreign telegrams for no longer period than six months, and the telegram to which you refer having been handed in more than six months ago, I am unable to comply with your request.'"

Induction Coils, Portable Batteries, and Electric Lights.—This was the title of a recent paper read by Mr. Charles J. Clark before the Glasgow Philosophical Society. He began by describing an apparatus he had invented for lighting gas by means of electricity. He then proceeded to show how, in the course of his investigations, he had discovered that by the use of iron wire interlaid with cotton he had succeeded in producing a perfect induction coil greatly less in size and at little more than half the cost of the coil formerly in use. He next showed how by using a similar coil a small portable battery had been constructed which could be utilised for many practical purposes, as, for example, in the ringing of bells, or the production of lights from small incandescent lamps. In illustration of the latter use, a gentleman by whom the author of the paper was accompanied showed an electric light burning in his scarf-pin, the electricity being supplied from a small battery carried in his waistcoat pocket. At the close of the paper Sir Wm. Thomson paid a high compliment to Mr. Clark for the industry and perseverance he had shown in perfecting his valuable inventions. The improvements he had made in portable batteries were of the greatest importance. He himself had been experimenting for years in the same direction with exceedingly little result, and he had often wished for a small portable battery such as he now saw realised. Setting aside such applications of the incandescent lamp as the placing of it in a gentleman's shirt pin or in the hair and dresses of ladies for the amusement of the public, as by the fairies in *Iolanthe*, Mr. Clark had shown how it could be turned to important practical uses. A railway traveller might, for example, have a lamp which would burn for an hour, which was as long as any one should read in such circumstances, and it would also be useful during the night or in the sick room, rendering unnecessary the objectionable practice of keeping gas on the peep or of striking lucifer matches. In reply to a question, Mr. Clark said he understood that some explosions had taken place with the gas lighter at the works of Mr. Crum, of Thornliebank. He had since, however, made such modifications in the apparatus as would render explosions in future impossible.—Mr. Thomas Gray next read a paper on a new seismographic apparatus, to be used at Tokio, Japan, in recording the time of occurrence of and the horizontal and vertical motion during an earthquake.

Electric Lighting for Warkworth Harbour.—We take the following from the *Newcastle Daily Chronicle*:—"In several of the principal engineering establishments on the banks of the Tyne electric lighting has come into use, and seems to give much satisfaction to both workmen and employers. There is, however, no use to which it can be more suitably put than the illumination of wharves, jetties, and coaling staithes, on account of the extent of its range. An example of this use of the electric light may be seen at the Lambton Drops, and Mr. Andrews, the owner of Warkworth Harbour, has decided to repeat the experiment. Indeed, so prosperous, comparatively speaking, has Warkworth Harbour become, that it has of late been felt that increased facilities for the shipment of coal at night should be provided. Amble, on the south side of the harbour, is the focus of a number of important collieries which ship a large quantity of coal annually. Shipments at night have been carried on under such disadvantages, owing to defective light, that it was determined to illuminate the quays and staithes on the Amble side of the harbour by electricity. Two companies, the Hammond Brush Lighting Company and the Jablochkoff Electric Light and Power Company (Limited) tendered for supplying the necessary apparatus. Mr. Andrews, in order to judge of the qualities of the two lights, arranged with the two firms to compete for the contract. The rival companies proceeded to fix up apparatus and lamps capable of lighting up the shipping berths, the staithes, and lines of railway running down to the quay. A well-adapted engine house has been erected near the quay, and in it has been placed a Tangye engine of about 12 horse-power, with cylinders 8in. diameter by 16in. stroke. This engine is of special design for driving electrical machines, and was exhibited at the Tynemouth Exhibition. It makes one hundred revolutions in the minute, and has been erected with special attention to steadiness. The Hammond Brush Lighting Company have put up six lamps, and the Jablochkoff Company ten lamps, each connected with a Gramme dynamo machine. Both lights were put to a test the other night, each being used a quarter of an hour, and then their combined illuminating power was tested. The result in each case appeared to be very satisfactory, and we would not venture to give an opinion as to the relative merits of the two lights. The result of the competition will not be arrived at until a month's trial, but whichever light is used it will, we believe, be found to be much better adapted to the lighting of coaling staithes than gas."

Telegraph Clerks' Grievances.—A large and enthusiastic meeting of Edinburgh telegraph clerks was held in the Ship Hotel on Saturday last, for the purpose of con-

Digitized by Google

sidering how far the Postmaster-General's recent scheme of revision had ameliorated the general condition of the service. The utmost unanimity of opinion was expressed regarding the failure of the scheme to adjust many pressing grievances that had been embodied in the united petition of 1881. The concessions already granted by Mr. Fawcett were gratefully acknwledged by those benefited, but it was pointed out that the great bulk of the staff, as was the case throughout the service, had received little or no benefit from the application of the scheme. Special attention was drawn to the fact that the London office enjoyed exceptional privileges, such as payment for Sunday duty and a higher status and maximum. Resolutions were passed specifying the several grievances that remain unredressed, calling upon the central committee to use every legitimate effort to obtain a parliamentary committee of inquiry, and expressing cordial sympathy with the clerk who had been suspended and removed from the Glasgow office for convening a meeting of his fellow clerks without the sanction of the authorities.—Other and similar meetings were held at Newcastle-on-Tyne, Birmingham, York, and elsewhere, on Saturday last. At Newcastle the clerks met at the Nag's Head, Cloth Market, delegates being present from Sunderland and Durham. In the course of the evening Mr. T. Spraggon (Newcastle), on behalf of the telegraph clerks stationed in the offices in the North of England, presented Messrs. G. Haddon and J. H. Clarkson with marble timepieces, as a slight recognition of the zeal and intelligence they have displayed in their endeavours to raise the status of the service. At Birmingham a meeting was held at the Acorn Hotel, Temple-street. The following resolutions were passed:—"That this meeting expresses its dissatisfaction with the scheme of revision applied to the Postal Telegraph Department in 1881, and is of opinion that the claims put forward in the petition of the telegraph clerks of the United Kingdom to the Postmaster-General of January 31, 1881, are just and reasonable, and, therefore, cannot regard as final any scheme which fails to satisfy those claims." "That we are of opinion that the best way of obtaining a satisfactory settlement of our grievances is through the appointment of a Select Committee of the House of Commons, and that we urge the Central Committee to use every legitimate effort to obtain that end." "That we strongly condemn the arbitrary action of the Glasgow authorities in their treatment of Mr. Robertson, of that office, by suspending him for posting a notice convening a meeting of his fellow clerks to consider what steps should be taken for the redress of their grievances, and that we offer him our hearty sympathy and support." "That this meeting tenders its cordial thanks to members of Parliament, the Press, and the public for their generous support in the past, and earnestly hopes that they will continue to render their support." Similar resolutions were passed at York.

Electric Lighting and Chelsea Vestry.—At a recent meeting of the Chelsea Vestry the report of the surveyor, Mr. G. H. Stayton, C.E., was read. It recapitulated what took place before the Board of Trade on the 17th Feb., congratulated the vestry at finding the conclusions of the board agreed with those of the vestry, and recommended that the new area arranged with the Brush Company be approved. Mr. Charles Mossop, the committee's chairman, moved the adoption of the report. He reminded the vestry that the scheme of the company was to take for their area of supply the whole parish, and for periods varying from two years and a half to twelve years and a half from the passing of the Act. The scheme might be said to be covered by the Act of Parliament, but it did not bear the stamp of Parliament, because it had never been suggested to the committee, nor was it ever referred to in the debates of either House. It seemed an evasion of what Parliament intended rather than a fair attempt to interpret the Act. The vestry opposed the scheme as regards space and as regards time. The latter was the more important item. Who could tell the value of a single year of electricity? The vestry has offered a very liberal alternative scheme. They have divided the parish into three blocks—A, B, and C—and the company has accepted block A, the easterly part of the parish. A is divided into two parts—blue and pink; blue is the smaller part, which the company has to light within two years and six months. As one stands in Pont-street, with his back to Sloane-square, looking to the north, there is a triangle of ground, of which Pont-street is the base and Knightsbridge is the apex. This takes in about fifty acres, including Lowndes-square, part of Cadogan-place, Charles-street (part), Sloane-street (part), Pavilion-road, Hans-place, Walton-place, and Walton-street (part). In round numbers this will cost £30,000. The company has to place their plans, specifications, and estimates before the Board of Trade, and if the figures are approved that sum will have to be set aside for this district, and all troubles as to payments for patents are at an end. Then the company can take a further part of the pink. The area must be agreed to by the vestry, and the money must be set aside for the second portion as before. This practically gets rid of bogus companies, and removes the difficulties as to subletting and assigning. The company have given up the clause in the provisional order which apparently overrides the Act, and this gets rid of the question as to over-head wires, and leaves the vestry with the control of their streets. Mr. Stayton's suggestion as to the wires being placed under the footways on each side of the street is accepted. The vestry has been for the last three months educating itself and (with the great aid that the Press has afforded them) other local authorities; and who knows that the Board of Trade has not been educated as well? All other local authorities will have the benefit of the vestry's labours. The Board wishes it to be known that they do not desire to interfere with local authorities. The vestry must decide which of two companies shall be preferred, and they must settle with the companies the area of supply. Mr. Culbertson seconded, thanking Mr. Mossop and the surveyor for the great trouble they had taken, and the motion was carried unanimously.

Extraction of Precious Metals by Electrolysis.—In a recent number of the *Chemical News* Messrs. Blas and Miest described several methods for the extraction of the precious metals from all kinds of ores by electrolysis. The following abstract of this paper was given in the *Journal* of the Chemical Society for January:—"The authors have discovered that if, in electrolysis, compressed ores are used as anode in a bath of an electrolyte containing the same metal as the metal of the ore, on the passage of the current the ore is decomposed, the sulphur, &c., being precipitated at the anode, whilst the metal collects at the cathode. Thus, with pure galena in a lead nitrate bath, the separation is complete and easy. If the ore contains silica as well, then the silica is deposited along with the sulphur, and remains uncombined. Antimony and arsenic, if present, behave in a similar manner, being precipitated as insoluble oxides. They are very easily separated by a subsequent electrolysis. When large quantities of arsenic are present, a part of it combines with the sulphur, and forms realgar or orpiment. When ores containing several metals are operated on, the precious metals, being most easily precipi-

Digitized by Google

tated, are thrown down first in the metallic state at the cathode under the action of a moderate current. The final separation of these metals requires very little battery power, for the mass of metal when dissolved under the action of the current regenerates sufficient heat for the ulterior separation of each metal separately. The products at the anode are extracted and purified by treatment with carbon bisulphide, and afterwards by separate electrolysis. The decanted carbon bisulphide solution of sulphur is distilled, the latter being left pure. If the ore is a polysulphide, and is mixed with much iron, sulphur and iron oxide are obtained in the first operation. These are best separated by electrolysing in a dilute sulphuric acid bath; pure sulphur is obtained at the anode, and basic iron sulphate at the cathode. By this process $1\frac{1}{2}$ horse-power is required to produce one kilo of copper from a sulphurous ore in one hour. As an example of the working with a complex ore, they describe the treatment of an argentiferous lead ore containing iron, copper, and zinc. The current being sufficiently strong, the iron and zinc will dissolve as readily as the other metals, but will not be precipitated so easily, therefore the solution will gradually become saturated with iron and zinc; the current is then regulated so that only the lead, silver, gold, and copper are precipitated on the cathode while the zinc remains dissolved as nitrate. As the bath becomes saturated, the iron yields to the zinc, and is precipitated to the bottom as ferric oxide, and as soon as the solution is nearly saturated with zinc nitrate it is syphoned off; the metals are then removed from the cathode, the sulphur and silica from the anode, and the iron oxide from the bottom, of course all separately. The sulphur, &c., and the metals are treated as above described. The zinc nitrate solution is treated with a small quantity of zinc oxide, which throws down the iron; the lead, copper and silver retained (if any) are precipitated by passing a current through the solution, using a zinc anode. The pure zinc nitrate may be treated by a stronger electric current if metallic zinc is required, or chemically if zinc oxide is wanted."

THE VIENNA ELECTRIC EXHIBITION.—The time fixed for the receipt of applications for space has been extended from the 1st to the 20th inst., by which latter date they should be in the hands of the secretary of the Society of Telegraph Engineers, 4, The Sanctuary, Westminster. We are also authorised to state that the committee at Vienna are making arrangements for a reduction in the rates of transit on all goods forwarded to Vienna for exhibition. From information received from Vienna it seems that the Exhibition is likely to prove thoroughly international, as well as comprehensive. Experiments as to the transmission of power will be carried out by M. Deprez and others, for which 300 h.-p. is available at different places round Vienna, and at various distances up to sixty kilometres. A recent telegram from the *Standard* Vienna correspondent gives some details which are of interest. With reference to his remarks on M. Deprez's experiments, however, we would refer our readers to an article in another column. He says:—"The Crown Prince (Rudolph), who is now on a visit to Berlin, will communicate with the German Committee, which, with the help of the Electro-Technical Society, and men like Dr. Werner Siemens, is expected to bring together a great collection of the most important recent appliances. The Americans will also probably take a prominent part in the Exhibition, but, owing to the great distance, they are among the latest to send in their announcements. Although England, Germany, and America are all late in their applications, the Vienna Committee have sufficient promises to make it pretty certain that those countries, in common with the nearer Continental States, will be well represented. Such an opportunity, in fact, as the Vienna Exhibition will offer for the extension of the electric light and other applications of electricity in the East of Europe, in Russia, Roumania, Servia, Greece, and Turkey, as well as in Austria and Hungary, is not likely to present itself again for a long time to come. The Exhibition will be held in the Prater, the great park of Vienna, and the favourite resort of the vast population of the city throughout the summer. The building in which the display will be collected is the Rotunda, the largest covered hall upon the European Continent. The space over which this edifice extends is more than a quarter of a million square feet, being more than double the area available at the late exhibition at Munich. Among the principal features of the Exhibition I may mention, in the first place, the exhibits of M. Marcel Deprez, whose developments of electric art in the way of transmission of electric power are among the most important of recent times. At Munich M. Deprez was able to use in the Exhibition the water power furnished by a small cascade thirty-five miles distant, the medium of transmission being nothing more than an ordinary telegraph wire. The loss of power then, however, was slightly over 60 per cent. By the help of improved machinery he has already reduced this loss very considerably, and he expects to show still better results at the Vienna Exhibition, where his experiments will be shown on a grand scale, and where he promises to prove to demonstration the entire correctness of his views on the transmission of electric force. There will likewise be rivals in the same section in the persons of M. Gravier, of Warsaw; M. Ganz, of Pesth; and M. Krizik, who is already known as the inventor of the Pilsen lamp. M. Gaston Planté, inventor of the accumulator, and M. Gautheret will also be among the exhibitors in this new field. Another department in which much that is novel and surprising will be shown will be that having to do with scientific measurements connected with electricity. Since the Munich Exhibition there has been remarkable progress made in this section, which will be fully illustrated in Vienna. The measurement of the degree of light in the various electric systems will here be illustrated. There will also be a few new systems of electric lighting shown, both of the arc and incandescent descriptions. Messrs. Krizic and Scoda, of Pilsen, will show a single arc light equal to twenty thousand candles in effect, and produced by a sixty horse-power engine. The Société Anonyme, of Paris; Edison's Company, of New York; and Deckert and Thomalto, of Vienna, will also compete with various novelties in this department. Another interesting portion of the Exhibition will refer to new applications of electricity for various scientific purposes, including electric optical instruments, medical appliances, apparatus for the examination of the interior organs of the body, and electrolithic batteries. There will also be new electric railway signals, electric rail shifters, point indicators, electric type-printing with single wire, and a new phonophone for musical transmission. There will be an electric railway running through the principal avenue of the Prater to the Exhibition. Some of the Vienna theatres are also to be connected with the Rotunda by telephone, so that the performances may be heard in the Exhibition. The Baden Theatre, ten miles distant, will be similarly connected. From this somewhat brief sketch it will be seen that the Vienna Electrical Exhibition of 1883 promises to be full of interest, not to the electricians and specialists only, but to the travelling public generally."

CURRENT ENERGY.—III.

BY OLIVER HEAVISIDE.

We have next, in natural order, to consider the potential energy of a current system on itself, as distinguished from its energy with respect to another system. The last being called the mutual energy, we may for brevity term the former the self-energy, just as the induction of a current on itself is called self-induction. The meaning of self-energy follows plainly from that of mutual energy; and hence, after the method previously given (p. 343), we may define the self-energy (potential) of a current system to be amount of work spent by externally applied forces against the electro-magnetic forces in building up the system by bringing together to their required positions from an infinite distance all the infinitely fine tubes of current into which the system may be split up, each infinitely small current being of constant strength. Now this amount is always negative (as is plain in simple cases, and is proved for an arbitrary system below), though the mutual energy of two systems may be positive or negative; hence the self-energy (potential), with sign changed, is the work needed to pull the system to pieces against the electro-magnetic forces, finally bringing it to a state of division into infinitely fine tubes, infinitely widely separated.

The calculation may be made by the same method of pairing tubes as for the mutual energy, with one important difference, however, which, when attended to, allows the method to give us the formula for the self-energy. Divide the system into, say, n tubes, and remove them, one at a time, to an infinite distance. Or, simply turn any tube in the act of removal into such a position that the total amount of magnetic force through it arising from that part of the system which remains is *nil*, and then cancel it. The required total amount of work performed is obviously the sum of the mutual energies, first of No. 1 tube with respect to the remaining $(n-1)$; then of No. 2 with respect to the remaining $(n-2)$, and so on. Thus, in pairing the tubes, we count each once only with respect to all the rest, or we form all the different pairs that can be made in the system.

Now, imagine there to be another system, exactly equal to the first, and coincident therewith. In calculating their *mutual* energy, we should form all the pairs that can be made, taking one member from the first, and the other from the second system. Now, we have, for example, the mth tube in the first paired with the n'^{th} in the second system, and also the n'^{th} in the first paired with the m'^{th} in the second. But the energies corresponding to these two pairs are equal, by the assumption that the systems are exactly equal. So the pairing is the same as if, in the previous case (for the self-energy), we had counted every pair twice over, with only this difference, that we have additional pairs 1,1′, 2,2′, 3,3′, &c., the accents referring to the imagined system. But the sum of the energies corresponding to these pairs, when the subdivision is carried to extremes, becomes infinitely small compared with the sum of all the rest. Hence we have the result that the self-energy of a system is exactly one-half its energy with respect to an exactly equal coincident system. The latter we know to be $\Sigma\overline{AC}$, where C is the current and A the vector-potential of either system. Consequently, if M_1 be the self-energy, we have

$$-M_1 = \frac{1}{2}\Sigma\overline{AC} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Any other method, properly carried out, will lead to the same result. Thus, first divide the system into two coincident systems, each of half the strength, and, therefore, having the vector-potential halved as well as the density of current, and separate them. The work done is $\frac{1}{2}\cdot\frac{1}{2}\Sigma\overline{AC}$, being their mutual energy, with sign changed. Next, similarly divide the two halves into systems of a quarter the currrent density and vector-potential, and separate as before. The work done is $2\cdot\frac{1}{4}\cdot\frac{1}{4}\Sigma\overline{AC}$. In the third similar operation the current and vector-potential are $(C \div 8)$ and $(A \div 8)$ and there are four pairs; hence the work done amounts to $4\cdot\frac{1}{8}\cdot\frac{1}{8}\Sigma\overline{AC}$. Carry this on *ad infinitum*, and sum up the amounts of work spent. The result is

$$\Sigma\overline{AC}\left(\frac{1}{4}+\frac{1}{8}+\frac{1}{16}+\ldots\right) = \frac{1}{2}\Sigma\overline{AC} \text{ as before,}$$

since the sum of the series $= \frac{1}{2}$.

Collecting results, let M_1 and M_2 be the self-energies, M_{12} the mutual energy of two arbitrary systems, in which C_1 and C_2 are the currents, and A_1 and A_2 the vector-potentials, and let M be the complete energy. Then we have

$$-M = -(M_1 + M_2 + M_{12}) = \frac{1}{2}\Sigma\overline{A_1C_1} + \frac{1}{2}\Sigma\overline{A_2C_2} + \Sigma\overline{A_1C_2} \quad . \quad . \quad . \quad (2)$$

where, instead of the last term, we may write $\Sigma\overline{A_2C_1}$.

We may easily show that (2) is consistent with (1) by regarding the two systems as a single one. For the actual vector-potential at any point is the vector-sum of A_1 and A_2, say A. Now if we substitute for the last summation in (2) one half of $(\Sigma\overline{A_1C_2} + \Sigma\overline{A_2C_1})$, which we may do because the two sums are equal, and rearrange terms, we get

$$-M = \frac{1}{2}\Sigma(\overline{A_1C_1} + \overline{A_2C_1}) + \frac{1}{2}\Sigma(\overline{A_1C_2} + \overline{A_2C_2})$$
$$= \frac{1}{2}\Sigma\overline{AC_1} + \frac{1}{2}\Sigma\overline{AC_2}.$$

(See rule on p. 343). Therefore, if the systems nowhere overlap, this is reduced to $\frac{1}{2}\Sigma\overline{AC}$, extending the summation over both systems. And when they do overlap it is the same. For in the overlapping parts the actual current is the vector sum of C_1 and C_2, hence we are reduced to $\frac{1}{2}\Sigma\overline{AC}$ always, agreeing with equation (1) for the self-energy of a system.

There is another very important and significant expression for the energy, which involves a transformation of an extraordinary character. Expressed generally, it amounts to this:—Let A be any vector function of no convergence, B its curl, and C that of B, then

$$\Sigma\overline{AC} = \Sigma B^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

the summations being taken throughout all space; or, which comes to the same thing, the first summation extended to all places where C exists, and the second over all space where B exists. A, B, C are here defined exactly as for the volume-element of a current, viz., amount crossing unit of area × volume, and taking the volume-element as the unit volume. By making use of the fundamental theorem connecting a vector and its curl, and by following the tubes of flow in our summations, the proposition admits of proof in a manner which makes evident how the transformation takes place.

Since B and C are non-converging, these systems may be completely divided into tubes of flow (*i.e.*, of flow as applied to a liquid), which are all closed. We shall first prove (3) in the case of a single tube of C, which may have any form, but is of indefinitely small section; *i.e.*, C = 0 everywhere except along a certain closed channel across every section of which we have a constant amount of C, which we may call C_1. Let B_1 and A_1 be the corresponding values of A and B. (A_1 is the vector-potential of C_1, and B_1 the curl of A_1, as before shown.) We know by the fundamental relation (Theorem II., p. 56 *ante*) that the line-integral of B_1 once round any closed curve = whole amount of C_1 through the curve; hence the line integral is zero unless the tube of C_1 goes through it (the closed curve). Now, the system B_1 is wholly made up of closed tubes, and since, if we integrate B_1 once round one of them, we always get a finite result (because the direction of B_1 is along the tube), it follows that *all* the tubes of B_1 pass through the circuit of C_1 and complete their circuits outside.

Let any surface be described whose edge is bounded by the

Digitized by Google

circuit of C_1; then, by what was said last, it cuts all the tubes of B_1. Next, let it be so situated as to cut them at right angles, and describe a series of other surfaces indefinitely close together, all similar to the first in that they are bounded by the circuit of C_1 and cut the tubes B_1 perpendicularly. This is possible, because in space where B_1 has no curl, that is, wherever $C = 0$, or everywhere except within the tube of C_1, B_1 may be derived from a scalar potential; and these surfaces are the equipotential surfaces. (We need not consider any correction in the following due to B_1 within C_1, because we take that space infinitely small.)

We have to prove that $\Sigma \overline{A_1C_1} = \Sigma B_1^2$. Now the summation $\Sigma \overline{A_1C_1}$ extends only to the tube of C_1. Hence

$$\Sigma \overline{A_1C_1} = C_1 \times \text{line-integral of } A_1 \text{ once round } C_1 \quad . \quad . \quad . \quad (4.)$$

(not meaning round C_1 in the sense that a tube of B_1 goes round C_1, but along the tube of C_1). But $B_1 = \text{curl } A_1$, therefore (4) becomes (by Theorem II., p. 56)

$$\Sigma \overline{A_1C_1} = C_1 \times \text{integral of } B_1 \text{ over any surf. bounded by } C_1 \quad (5.)$$

But again, $C_1 = \text{curl } B_1$, therefore (Theorem II.)

$$C_1 = \text{integral of } B_1 \text{ once round any tube of } B_1 \quad . \quad . \quad . \quad (6.)$$

Hence, by substituting (6) in (5) we find

$$\Sigma \overline{A_1C_1} = \left.\begin{array}{l}\text{line-integral of } B_1 \\ \times \text{ surface-integral of } B_1\end{array}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7.)$$

It is important to notice that *any* tube of B_1 will do for the line integral, and *any* surface bounded by C_1 for the surface-nitegral. But all the tubes of B_1 are cut by the surface, and when it is an equipotential one they are cut perpendicularly. The same being true for the whole series of equipotential surfaces, it follows that the product of the line and surface-integrals in (7) includes every place where B_1 exists; hence we may ignore the tubes completely, and write

$$\Sigma \overline{A_1C_1} = \Sigma B_1^2,$$

extending summations through all space; whence the proposition is proved in the case of an infinitely fine tube of C.

Now, in the general case of an arbitrary system, divide C into its tubes, and consider one of them, say, C_1, as before. We have A and B instead of A_1 and B_1, and $\Sigma \overline{AC_1}$ instead of $\Sigma \overline{A_1C_1}$; hence, by the previous reasoning,

$$\begin{aligned}\Sigma \overline{AC_1} &= C_1 \times \text{line-integral of A round } C_1, \\ &= C_1 \times \text{surface-integral of B,} \quad . \quad . \quad . \quad (8)\end{aligned}$$

the latter being over any surface bounded by C_1. Divide space as previously by means of the equipotential surfaces of B_1 and the tubes of B_1 (not of B). The tubes of B will not, save exceptionally, cut the surfaces at right angles, hence we have to take the normal component of B in the surface integral in (8); that is, B cos (BB_1). Also C_1 has the same relation to B_1 as before; therefore, by (6) and (8),

$$\Sigma \overline{AC_1} = \left.\begin{array}{l}\text{line-integral of } B_1 \\ \times \text{ surface-integral of B cos } (BB_1)\end{array}\right\} \quad . \quad (9)$$

But $BB_1 \cos (BB_1) = \overline{BB_1}$, and the space integrated over is as before; therefore,

$$\Sigma \overline{AC_1} = \Sigma \overline{BB_1}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

Similarly for a second tube of C, say C_2, we shall have $\Sigma \overline{AC_2} = \Sigma \overline{BB_2}$, and when we do the same for all the tubes of C, and add, we get

$$\Sigma \overline{AC} = \Sigma (\overline{BB_1} + \overline{BB_2} + \overline{BB_3} + \ldots).$$

But B is the vector sum of B_1, B_2, &c.; whence the bracketted quantity in the last equation $= \overline{BB} = B^2$; therefore, finally,

$$\Sigma \overline{AC} = \Sigma B^2. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

for any arbitrary system.

[I think it was a philosopher who propounded the theory that men always thought in some language; an Englishman in English, for example; always, if he knew no other language; otherwise he might think in either. Not to raise the obvious objection that persons dumb from birth should, according to this, have no thoughts at all, the theory is certainly proved to be false by an examination of such a transformation as the above. As regards the case of a single tube of C, if only the geometrical conditions are pictured in the mind, the division of space into small cubes by the tubes of B_1 cut across by the equipotential surfaces of B_1, the transformation becomes as self-evident as an axiom, and no form of words or sentences is necessary. The less one is cumbered with them the better. And, although the extension to an arbitrary system is less easy, it is still easier to be pictured than logically demonstrated. The transformation might have been seen quite intuitively; it is only when one has to prove it to some one else that clothing the thoughts in words becomes necessary; and, even then, the clothes do not correspond to the original thoughts, but to those arising in the act of description, and both words and thoughts require to be readjusted, perhaps, two or three times before they will mutually fit with any decency. The Cartesian transformation, breaking up each of the vectors A, B, C into three rectangular components, is short enough, but with a total absence of visible reason and significance.]

In applying (11) to electro-magnetism, we have to remember that, B standing for the magnetic force, C for current, and A for the vector-potential, we have $B = \text{curl } A$, but $4\pi C = \text{curl } B$. Consequently the potential self-energy of a current system is, by (1) and (11)

$$-\frac{1}{2}\Sigma \overline{AC} = -\frac{1}{8\pi}\Sigma B^2 \quad . \quad . \quad . \quad . \quad (12).$$

Now, go back to (10). The left-hand member is the mutual potential energy with sign changed of an arbitrary current system whose vector potential is A and of a single tube of current C_1. In the same manner as (11) followed from (10) we may easily show that the mutual potential energy of two arbitrary systems denoted by the suffixes 1 and 2 is

$$-M_{12} = -\Sigma \overline{A_1C_2} = -\Sigma \overline{A_2C_1} = -\frac{1}{4\pi}\Sigma \overline{B_1B_2} \text{ also } (13).$$

Hence, in terms of the magnetic force, equation (2), for the complete energy of two systems, becomes

$$-M = \frac{1}{8\pi}\Sigma B_1^2 + \frac{1}{8\pi}\Sigma B_2^2 + \frac{1}{4\pi}\Sigma \overline{B_1B_2},$$

which is obviously reducible to $\frac{1}{8\pi}\Sigma (B_1 + B_2)^2$ or $\frac{1}{8\pi}\Sigma B^2$ if B be the actual resultant magnetic force.

The expression $\Sigma B^2 \div 8\pi$, that is, the potential energy with sign changed, may be proved, though not without reference to induction phenomena, to be the Energy of a current system, or its capacity for performing work in various ways. The form in terms of the square of the magnetic force, due originally to Sir W. Thomson, is of great significance in the theory of action through an intervening medium, as opposed to action at a distance.

THE ELECTRICAL EXHIBITIONS.

This winter we have to chronicle two exhibitions, the one at the Crystal Palace, the other at the Aquarium. As our readers know, the former of these is a mixed exhibition—being devoted partly to electricity and partly to gas—while the latter is purely electrical. The exhibition at the Palace has, we are told, proved very attractive, although the electrical portion is by no means extensive or complete. The exhibition at the Aquarium is also in a very incomplete state; indeed, the formal opening has been put off from time to time because of such incompleteness, but it is stated on good authority that it is to be really opened this week. The promoters of this exhibition, no doubt, hope that the special appropriation of the Aquarium for such a display is to be found in Dante's line, which may be rendered:—

Whereby in compass small may much be shown.

For, when compared with Paris and the Palace Exhibition, the space is, indeed, small. We gather, however, that the most will be made of the space at command, and should the exhibitors who have promised fulfil their promises there will be a goodly display of light apparatus. Several of the larger companies are not directly represented at either of these

Digitized by Google

exhibitions, thinking, no doubt, to keep their energies for Vienna or Berlin, or other international exhibitions. It may be that their wares are so well known as to need no further display. At any rate, the absence of one class of exhibitors cannot but be of advantage to another class, and, in some manner, to the public generally, allowing, as it will, some of the poorer and more modest inventors to show what they can do, and so allow of comparisons which could hardly be made where one man shows two or three lamps in proximity to a dozen or a score of another exhibitor.

There is or will be at the Aquarium a number of new arc lamps, as well as new dynamos, new secondary batteries, and other new apparatus connected more or less with electric light work. We will commence our report with a description of a new dynamo.

The Lumley Dynamo.

The peculiarities of this dynamo are in the construction of the armature. The machines have been constructed by Messrs. Paterson and Cooper, from the designs of Mr. Lumley. According to a list we have before us, two classes of machines are made. One kind for incandescent lighting, the other for arc lighting. Several types of machines are made in each class. Thus:—

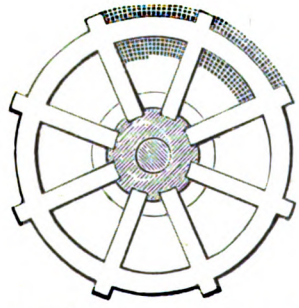

Fig. 1.—Armature Core of the Lumley Dynamo.

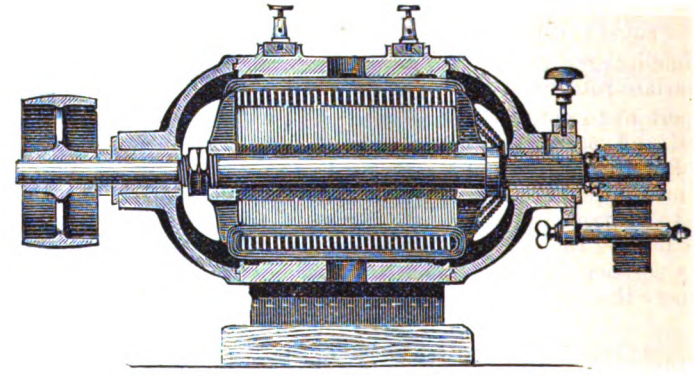

Fig. 2.—Section of Lumley Dynamo.

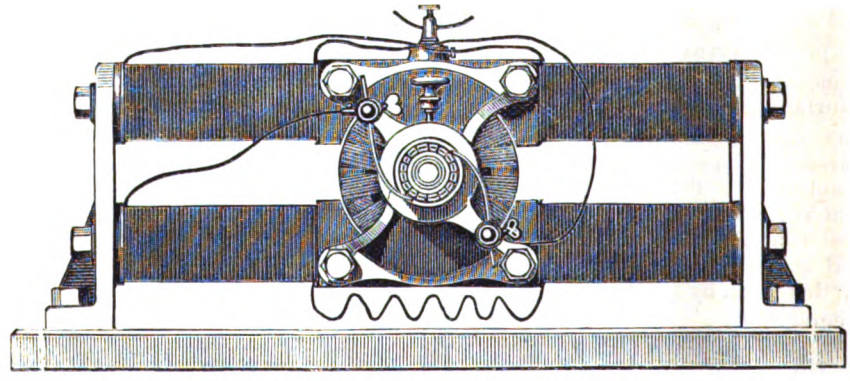

Fig. 3.—View of the Lumley Dynamo from the Commutator side.

For Incandescent Lighting.		For Arc Lighting.	
No.	No. Swan Lamps, 20 C.-P.	No.	Indicated H.-P. required.
1B	50	1A	4
2B	70	2A	5
3B	100	3A	9
4B	200	4A	18
5B	500		
6B	1,000		

Indicated H.-P. required.	No. of Lights.
4	4
5	5
9	9
18	18

The above figures are those issued by the company. It will be seen that a very high efficiency is claimed. Taking the 45 volt Swan 20 C.-P. lamp as requiring 1·3 ampere current, the maximum number of lamps that could be maintained per H.P. would be less than 13. This, of course, supposes the whole of the energy to be expended in the lamp. If, therefore, with this machine between 11 and 12 lamps can be maintained per H.-P., the result is very good. Before entering into particulars regarding the construction, we may say that the machines are very compact, the 70 light machine, for example, measuring only 2ft. 6in. by 2ft. 6in. by 1ft. 5in. over all, and weighing somewhat less than 4½cwt. There is little difference in the field magnets to those of other machines. The arms are of cast iron, and of a flattish section. The shaft carries a grooved cylinder. The core of the armature consists of sheet iron discs cut into the form of a wheel, as shown in Fig. 1. The spokes of the wheel may or may not project beyond the rim, the other end of the spokes going into the groove on the shaft. The core is built up alternately of these iron discs and brass rings, the brass rings being placed at the shaft end of the discs, and being comparatively narrow. The core thus built up is wound longitudinally with insulated wire around the rims of the discs in the ordinary manner, each section or bobbin being separated by the spokes, and as these are equidistant the quantity of wire in each bobbin is similar. The discs are all punched by machinery. The armature, at least the larger sizes, can be wound by machinery, hence the cost of the machines is lessened, and the company claims it to be the cheapest machine in the market. The designers have also invented a new arc lamp, which is very simple, and will be seen at the Aquarium. We shall refer to this lamp in a future issue.

Messrs. Paterson and Cooper have favoured us with the following figures concerning these machines. Readings of a shunt machine gave 74·2 amperes current at an electromotive force of 46·25 volts at the terminals, the external circuit having a resistance of ·62 ohm, and the speed being 1,680 revolutions per minute. The resistance of the armature of the shunt machine is ·079 ohm, that of a series machine about 1 ohm, the resistances of the field magnets in the former case being 7·79 ohms, and in the latter about 1 ohm. The E.M.F. of the series machine is about four times that of the shunt. Altogether it will be seen the machine is one that will bear careful examination, and we hope to refer to it again during the exhibition. Fig. 2 shows a section of the machine, whilst Fig. 3 is a view from the commutator side.

THE (ELECTRIC) CONDUCTIVE AND INDUCTIVE CIRCUITS GEOMETRICALLY ILLUSTRATED.

BY F. C. WEBB, M.I.C.E.

(CONTINUED FROM PAGE 376.)

When a submarine cable is completely broken it frequently happens that the copper wire is broken half an inch or more from the place where the gutta percha envelope is fractured. In some cases the copper protrudes, and in others the end is within the gutta percha. When testing for the distance of the fault the resistance measured will be the resistance of the copper conductor to the fracture, plus the resistance caused by the end not maintaining a perfect earth connection, for the resistance of the small column of water, half an inch long and only about a sixteenth of an inch in diameter, is considerable. To eliminate this unknown quantity is the great difficulty in the way of finding the distance of the fault, for if the copper wire touched, say, the iron of the cable, the fault would give no resistance, and the resistance found when testing would be the actual resistance from shore to fault, from which, of course, the actual distance can be found. The discharge of the dynamic charge it will be seen (theoretically, at any rate) gives us the means of finding the resistance of the fault. For let A B (Fig. 53) be the actual resistance of the conductor to the fault, and B C that of the fault. Then, if we applied a battery at A, the resistance of which was D A and the electromotive force D E, we should have a dynamic charge which, instead of being equal to the triangle A F C, would be only equal to the figure A F G B. A portion of this dynamic charge, when A is put to earth, would go to earth at C and a portion at A. This last portion, the "return current," can be measured, and it is evident that

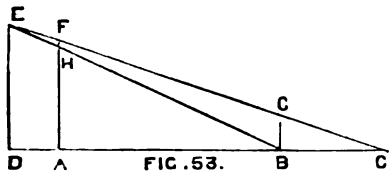

FIG. 53.

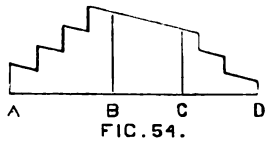

FIG. 54.

since, if the end always made good earth, then the portion discharging at C would bear some regular proportion to that resistance, that when the discharge (or "return current") is *less* than that proportion, then it must show that *some of the resistance is due to resistance having no electrostatic capacity.* If the line made a perfect earth at B (as by touching the iron wires), then the resistance would be A B, and the dynamic charge would be A H B, and if the resistance shown was A B, and we had a return current proportionate to the dynamic charge A H B, we should know that the end made a perfect earth, and, consequently, that the resistance shown by test was the true resistance to the fault. This reasoning I pointed out in a paper I read before the Institution of Civil Engineers on 23rd February, 1858. Since then Dr. Werner Siemens has solved the complete problem, and worked the proportions out, and Mr. Kempe has not only also done this, but devised instruments for taking the test accurately. The problem in its entirety is, it will be seen, very abstruse, because we have first to find the proportion of the dynamic charge that would, if there was a perfect earth at B, discharge at A. This, I believe, Mr. Kempe makes two-thirds of the total charge. Now, when the resistance is increased by the fault the total charge is increased, but not in proportion to the increase of resistance. It is less than it would be if all the resistance was due to cable by the amount of the triangle B G C. And again, of this total charge a greater proportion will come out at A than in the case of the charge A H B, so that the relation between this return current and the resistance shown is excessively complicated; but it has, nevertheless, been, as I have said, solved. In extreme cases, however, it is a guide even without the exact formula. For instance, suppose the resistance shown by test very great, say equal to two hundred miles, whilst the return current only equalled what would be given by two or three miles of cable, then we know at once by the great discrepancy that a great portion of the resistance is due to the fault. It happens sometimes that the resistance shown is infinite, from the end becoming completely sealed up. The gutta percha being the last to give way, and the cable, when the wires are gone, twisting round rapidly, draws the gutta percha over the end of the copper, and then twists it up in the most workmanlike manner. In such cases, by charging the cable up and measuring the discharge, we have the only means of measuring the distance, and this is, in fact, a very reliable test.

When a battery is in opposition to another it will take the form shown in Fig. 54, where A B is a battery opposing C D and having a greater electromotive force. The ends of submarine cables through polarisation set up an electromotive force, and this opposing the testing battery current causes the resistance measured to be either greater or less than the real resistance to the fault, according to the nature of the electromotive force set up. This is shown in Fig. 55, where A B is the real

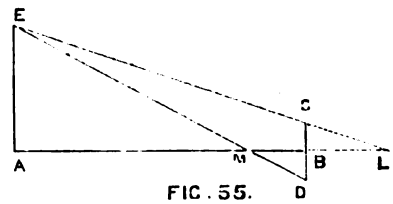

FIG. 55.

resistance to fault, and A E potential at A, when testing. Then if the electromotive force set up at the fault is B C (*i.e.*, positive), the resistance measured will be A L, too great by B L, and if the electromotive force set up is B D (*i.e.*, negative), then the resistance shown will be A M, which is too small by M B. It will be seen that B is not half way between M and L, and the mean between the two tests is not the accurate distance of the fault. However, I am not writing a treatise on testing, but only illustrating the subject geometrically, and before leaving the subject of the conductive circuit it may be well to illustrate geometrically a few of the ordinary testing instrument circuits. Thus, a differential galvanometer and resistance, being compared, is shown in Fig. 56. A E is the potential of the battery pole applied to instruments at one

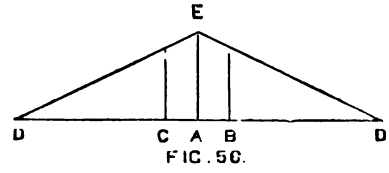

FIG. 56.

terminal, A C and A B resistance of the coils, and D C and B D the measuring and unknown resistances, the one being measured by the other. The current being equal in each coil when the needle is at zero, the steepness of the potential line in each branch of the circuit is equal, and thus that line cuts off equal resistances on each side of A.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—An extraordinary general meeting of this company will be held at St. Michael's Hall, George-yard, Lombard-street, E.C., on the 15th March, at two o'clock, for the following purposes:—1. To declare a dividend of £3 per cent. on the (reduced) capital of the company (in accordance with the recommendation contained in the annual report, dated January 3, 1883, adopted by the shareholders in general meeting on January 11, 1883) for the year ending September 30, 1882, the necessary resolutions for the reduction of capital having been duly passed and confirmed by the shareholders, and sanctioned by the Court on February 16, 1883. 2. To submit resolutions in accordance with a requisition signed by shareholders holding over 11,000 shares, referring to the conversion of existing Ordinary shares into Preferred Ordinary shares and Deferred Ordinary shares. Holders of share warrants wishing to attend the meeting must deposit the warrants at the offices of the company, with name and address, three days at least before the day appointed for the meeting.

CORRESPONDENCE.

THE INVENTOR OF THE TELEPHONE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As your editorial note of p. 374 invites me to give the references that I have indicated in evidence of Reis's claim to be the inventor of the telephone, which he designed for the express object of transmitting human speech and other sounds of all kinds, I have much pleasure in giving you the very same references which I have myself obtained from the published writings of Graham Bell ("Researches in Telephony," *Journal of Society Telegraph Engineers*, 1877) and of Edison (see "Prescott's Speaking Telephone," p. 218).

The following are a few of Bell's references:—

(1) "Telephonie," *Dingler's Polytechnisches Journal*, CLXVIII., p. 185, extracted from the *Jahresbericht des Physikalischen Vereins zu Frankfurt am Main*, 1860-61, p. 57-64.

This is a scientific memoir by Philipp Reis, having for title "On Telephony by the Galvanic Current." On p. 58 he says his endeavour was to find an instrument which should reproduce the total action of all the organs set in action in human *speech* (menschlichen Spräche), and that he took the human ear as model, because the tympanum of the ear could respond to all sounds. After discussing the problem of representing the pressures of the air in sound-waves by a "curve," he says that if it is possible at any place to reproduce vibrations having a similar "curve," the very tones will be reproduced. He then says that, taking his stand on the principles laid down, he has succeeded in reproducing the tones of various instruments, and to a certain degree the human *voice* (die menschliche Stimme). After describing his instrument—the well-known combination of a tympanum in imitation of that of the human ear, with an electric current regulator, consisting of an interrupting apparatus, which embodied the loose-contact principle of the microphone, and which is in many respects exactly like the interrupter in the Blake transmitter—he says (p. 62):—"I give to my instrument the name 'Telephon.'" Later on he says that the reproduction of human speech which he has attained is not so clear as to satisfy everybody, and that though the consonants are transmitted distinctly enough, the vowels are not equally so, and he proceeds to discuss why this is the case.

(2) *Brix's Zeitschrift des deutsch-oesterreichischen Telegraphen Vereins*, 1862, Vol. IX., p. 125. This article is also reprinted in *Dingler's Polytechnisches Journal*, 1863. Bd. CLXIX., p. 23.

This is a report by Inspector von Legat on Reis's telephone in its developed form. Inspector von Legat says that this instrument was able to reproduce single words uttered as in reading and speaking, though not so distinctly as it reproduced chords and melodies, which latter it transmitted with marvellous fidelity. He even added that the inflexions of the voice, the modulations of interrogation, exclamation, wonder, and command attained distinct expression!

So much for Bell's references; Edison's reference is the same as No. (2) of the preceding.

As to the publicity of these documents, permit me to refer you to the shelves of the British Museum and other public libraries.

I do not say that there is not plenty of further evidence, were such needed. But here I am quite content to accept the references given by such unimpeachable authorities as Bell and Edison. When they refer me to papers wherein Reis says in substance:—"I am the inventor of the telephone. My instrument is intended to transmit human speech and all other kinds of sounds that a human ear can hear, and it succeeds in doing so, though I find to my disappointment that it is not yet quite perfect, because though single words and consonants come through all right, the vowels are not clear," I am bound to believe, on the authority of Bell and Edison, who give me these references, that Reis's modest claim is just. And I am bound to this belief still more strongly because I find, when I make careful trial of Reis's own telephones, that they will do exactly what he said they were intended to do—namely, transmit human speech to a distance by the agency of the galvanic current.

You have, Mr. Editor, most aptly said that the question is what was *the kind of success aimed at* and attained by Philipp Reis? and I entirely agree with you that this question is not in the least degree affected by whether Philipp Reis is dead or alive. Though himself be dead, and the task of defending his memory from outrage falls to others, his words still live to testify in the most unmistakable manner to the aim which he set before himself, and to the measure of success which he attained in his invention of the telephone.—Yours, &c., SILVANUS P. THOMPSON.

Bristol, March 4, 1883.

P.S.—There is a slight *erratum* in line 12, from bottom of p. 373, where, by mischance, the word which I wrote has been altered from *perfected* to *perfect*. Philipp Reis's telephones of 1862 were not perfect, but were perfected instruments compared with those he showed to the Physical Society in 1861.

THE ERG-METER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In Mr. Shoolbred's lecture "On the Measurement of Electricity for Commercial Purposes" a description was given of Professors Ayrton and Perry's erg-meter, certainly the most simple of all the instruments described at this lecture. In the discussion Professor Perry laid great stress upon the point that in the erg-meter no new mechanical difficulties have to be overcome, as the experience acquired by the Clerkenwell clockmakers during the last 150 years would be quite sufficient to produce a mechanically perfect instrument. This is undoubtedly the case. But is the instrument mathematically correct? Mr. Shoolbred did not enter into its theory so as to prove that the retardation of the clock during a certain time is strictly proportional to the energy consumed in that time. To give an example:—Say, a householder uses during one week 10 amperes (at 100 volts) for four hours every day, and finds that his clock has retarded one hour during that week. Now, assume that in the following week he uses 50 amperes (at 100 volts) for eight hours every day, will the retardation of the clock be ten hours during this second week? This is a question which does not depend upon the experience of the clockmaker, but simply upon the correctness of the principle on which the erg-meter is based. Can any of your readers inform me where a theory of this instrument can be found; or, if none has as yet been published, would it be asking too much of Professors Ayrton and Perry's kindness to give to the world mathematical proof that the erg-meter is not only exceedingly simple and ingenious, but also accurate?—Yours, &c., PENDULUM.

TELEPHONIC TRANSLATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Without in the least traversing Mr. T. D. Lockwood's assertion, to which you refer in your last issue, that he used telephonic repeaters similar to mine in the United States in the autumn of 1879, I beg most emphatically to assert that such instruments were unknown in the United Kingdom at the time mine were designed, and, further, that none of the many American electricians who were brought over early in 1881 by the National Telephone Company, and who were engaged expressly because they were supposed to be conversant with all the latest American improvements, had ever heard of such a device. Two of these gentlemen even reported to the company that the only solution of the problem was to run metallic loops for every subscriber, and one of them, while I was making my experiments, repeatedly urged me to lose no time, as he was anxious to get a certain trunk wire working. As Mr. Lockwood states that he found his repeaters of little practical value and abandoned them in consequence, it is obvious that they could not have been of the same construction altogether as mine, which are, in

Digitized by Google

every way, a complete success. The reference he makes to the Blake transmitter coil is not quite in order. That is a coil for transforming quantity currents into tension currents; mine is one for inducing tension currents by tension currents. A Blake transmitter coil will not translate between wire and wire, nor, on the other hand, will my coil do the duty of a Blake transmitter one.—Yours, &c., A. R. BENNETT.

134, Douglas-street, Glasgow,
March 3rd, 1883.

SAFE WORKING CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the last number of *The Electrician* the supplement contains some data which are very much wanted. As I have worked a good deal in this direction myself I may perhaps be permitted to make a few remarks. The table gives the current which can be *safely worked* in conductors of different thicknesses. Now, what is meant by safe working? Most people would say that to work safely we must have a current which does not heat the wire more than a certain number of degrees. I have already pointed out that, theoretically, the square of the safe current should be proportional to the cube of the diameter, although in practice it seems to be not exactly so. But I have also shown that certainly the safe current is neither theoretically nor experimentally in any degree proportional to the area of section of the wire. Yet this is the law which is assumed in the table which forms the supplement. The subject is most important, and such a table is, as I have said, very much wanted. I hope, therefore, that you will inform us upon what experimental data the table in question is founded, what is meant by "safe working," whether the wire is bare or covered, if the latter with what thickness of material, and what temperature is considered permissible.—Yours, &c.,

34, Great George-street, Westminster, March 5, 1833. GEORGE FORBES.

THE SUPERPOSITION OF CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The principle that, in a network of wires, the resultant current may be calculated as the sum of the separate and independent effects of the sources of E.M.F. in the system is very well known and used (it must be very generally used, I should say) by those who have to perform electrical calculations.

It results at once from the well-known and fundamental principle that the stream function belonging to any fluid motion is additive; and the recognition of this principle involves *ipso facto* the perception of the additive nature of the currents in a network. The employment of this principle simplifies calculation in Wheatstone bridge and other network arrangements of wires, as Mr. Blakesley observes in his article of last week.—Yours, &c., GEO. M. MINCHIN.

R.I.E. College, Cooper's Hill.

AN ARC LAMP TO BURN AT ANY ANGLE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I beg to state that I have devised an arc lamp to burn at any angle, the same being done by an improved form of clutch, which forces the carbons to their just position by small, quick impulses. Should like a communication from "Inquirer" should he require such a lamp.—Yours, &c.,

OLIVER H. KENNEY.

1, Alice-villas, Woodhouse-road,
Leytonstone, E.

[We have received a similar letter from Mr. R. Bowman, of the same address, which evidently refers to the same lamp. —ED. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In answer to your correspondent, "Inquirer," I beg to inform him that my lamp, now exhibited by Mr. Werdermann, in the Alhambra Court and Tropical Department, Crystal Palace, can be made to burn at any angle, or will burn by having the carbon fed upwards any length that may be required for lamp posts.—Yours, &c., JOHN LEA.

43, Clarence-gardens, Osnaburgh-street,
Regent's Park, March 6, 1883.

LINES SUGGESTED

ON READING "W.'s" LETTER IN "THE ELECTRICIAN," MARCH 3, 1883.

TO THE EDITOR OF THE ELECTRICIAN.

The man who signs with a zig-zag-zig,
Followed by spirals five,
Doesn't believe
In accumulators—
Doesn't, as he's alive.

Who is the man with the zig-zag-zig
Followed by spirals five?
'Tis Mister ————,
Who, anti-gassy,
Still on would his amperes drive.

CHARLES CHABOT'S GHOST (expert).

"THE ELECTRICIAN" SUPPLEMENT No. 2.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have found an error in equation (*a*):—

$$96 \text{ per cent. conductivity } R = \frac{1003265}{d^2}$$

in Supplement for March 3. It ought to be

$$96 \text{ per cent. conductivity } R = \frac{\cdot 003265}{d^2}$$

for 100 yards.—Yours, &c., W. J. BILLINGS.

12, Bingfield-street, N.

TELEPHONES AND FIRE ALARMS IN RIO DE JANEIRO.

A correspondent writes from Rio de Janeiro, under date Feb. 9, as follows:—

SIR: I noticed in a recent copy of the London *Times* an advertisement of the "Fire Alarm and Signal Company," for doing the service performed in the United States by the so-called "American District Telegraph Companies." It may interest you to know that, even in this remote capital, we have recently established such a company, furnishing messenger, police, fire-alarm, and telephone service, which is meeting with a very satisfactory reception from the Rio public. Its officers are:—C. P. Mackie, president; W. I. Donshea, general superintendent and electrician; and Victor Dias, manager. Mr. Mackie is the attorney in Brazil of Professor Alexander Graham Bell, and the founder of telephony in the Empire—the Government having given him the first concession in 1879—and Mr. Donshea was sent out by the Continental Telephone Company in 1880 to erect the exchanges established under this concession.

TELEPHONIC COMMUNICATION WITH THE "HOUSE."—Mr. Ritchie asked Mr. Shaw-Lefevre the other day in the House of Commons when telephonic communication would be established between the House and the Exchange in the City. The reply was "before long." Mr. Ritchie seemed to think this somewhat vague, and drew Mr. Lefevre's attention to the fact that "any mercantile house in the city could have it (telephonic communication) in twenty-four hours."

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended February 28 were £3,475, as compared with £2,649 in the corresponding period of 1882.

ANSWERS TO CORRESPONDENTS.

P. Howell.—Thanks for cutting from daily paper. Before giving any opinion on the wonderful results said to have been obtained by Professor Lendstroem, of Helsingfors, we should like to have some more scientific and satisfactory source of information to base our judgment upon. The account may be true, and—it may not.

W. T. F.—Thanks for hints re "Directory." We noticed the ludicrous confusion of the aurora with a lunar rainbow which pervaded the Scotch Press recently. As you say, it was rather odd that the two should be confounded, considering that there was no moon on the night when the aurora appeared.

T. H. S. Hawker.—The "Electric Light Arithmetic" is published by Messrs. Macmillan and Co., Bedford-street, Covent-garden, W.C.

Capitalist (999).—*An answer awaits you here.*

A Constant Subscriber.—We cannot insert letters unless the name and address of the writer is sent, not necessarily for publication, but as a guarantee of good faith.

J. T.—We do not know the exact status of the electrician in the position you mention, but should imagine he ranks with the assistant-engineer—probably as second engineer. The introduction is so modern that no well-defined position has yet been established.

J. G. (Blackburn).—Since answering you in our last issue, we have ascertained that the St. George telephone is made by E. Terraneau, 1, Sherborne-lane, King William-street, E.C.

MR. EDISON'S CANDID OPINION.

America, which claims to be the birthplace of all modern inventions, has, indeed, perfected one which no other country will dare to challenge, and few, it may be hoped, will care to imitate—we mean the art of interviewing. The wielders of this infallible weapon of personal inquisition appear to have inspired such universal terror that, like Mrs. Bond's ducks, their intended victims "come and be killed"—or questioned—as a natural penalty of fame, or flavour, which it would be almost profanity to try to escape. Our comparison fails us here, however, for whereas the ancient dame herself provided all the stuffing to console her doomed flock, stuffing alone is what modern *Mr.* Bond is in search of, and this his human ducks themselves are compelled to supply. Whether they consent to be interviewed or no his report will appear all the same, and they have at length come to consider it best to provide their own stuffing rather than leave it to the imaginative taste of some one who has, perhaps, never seen so much as the tip of their feathers.

Considerations of this kind doubtless weighed with Mr. Edison when he resigned himself to the emissary of the *Herald*. He probably could not evade the ordeal, and if he had done so the alternative would possibly have been the more painful operation of the two. Better say what you would rather not have said than be represented as saying something you never even thought. Thus we have got Mr. Edison's opinion—his candid opinion about some things, and professional opinion about some others besides. So candid, indeed, was the first instalment of his deliverance, which we reprinted in our columns three weeks ago, that some people exclaimed, as of Saul of old, is Edison also among the prophets? And not without reason, for it is an undeniable fact that on this side the Atlantic Mr. Edison's name, ever since the great panic in gas shares, has been associated with that of the Philistines. The association was doubtless undeserved, and the *Herald's* inquisitor is to be thanked for setting this matter right with the English public. In this relation perhaps the concluding words of the final report which we print to-day may be taken both in explanation and excuse. "If," says Mr. Edison in dismissing his interrogator, "If I show that electric lighting is an exceedingly profitable business, when done on a large scale, the public would be dissatisfied with the prices we demand. On the other hand, if I say we can compete with gas, and have to sell the electric light for about the same, then the investing public will put no money into it. So you see"—the interviewer was so to see—"I am in a dilemma about making statements as to cost."

This was Mr. Edison's dilemma, and to some extent, if it had been stated at the outset, perhaps the whole of what followed would have been read with a considerable discount. Still it is candid, and as such is a welcome contribution to the literature of financial dilemmas. Its relegation to the very end of the report enabled us to enjoy the unalloyed satisfaction of perusing all that preceded it. More especially was this the case in regard to the latter portion of the discourse, which dealt chiefly with electrical storing. The great American inventor does not believe in storage batteries. Doubtless he has invented numbers of them; but, if so, they have been successful only in giving his moral senses a rude shock. Storage batteries bring out a man's latent capacity for lying, Mr. Edison declares, and he, probably, agrees with our English correspondent who regards them as a device of the Evil One. About that class of article the interviewer's victim experienced no "dilemma" whatever, the investing public not being then in

Digitized by Google

his mind's eye — the "investing public" meaning, apparently, "my stockholders," who, of course, are guiltless of storage batteries.

Upon one other subject also Mr. Edison was almost equally candid. Arc lighting is nearly as great an imposition as electrical storing, and a much greater nuisance. In America it would appear that arc lighting is necessarily effected by means of slack wires slung overhead, and that it does much mischief to something or somebody every day of the week. Morality fails to cope with this enormity, theology alone will touch it:—"If arc light were good for any kind of illumination, it appears to me the Almighty would have given us eyes different from those he has bestowed upon us." This is decisive as touching the eye, whether regarded as an optical or as an æsthetic organ. We are not disposed to quarrel with the statement, though we should prefer to put it differently; but there is no accounting for what one may be tripped into saying while under the influence of a newspaper medium. When a man is made to talk of the community fully realising "the subtlety, pervasiveness, and indeterminableness of the perils arising from vagrant electricity," we feel sure that either he is speaking about matters of which we have no experience, or else that he is parting with his stuffing too liberally. But as we are not famous, and have not yet been interviewed, perhaps we ought not to judge.

On the subject of incandescent lighting Mr. Edison speaks with authority, and what he has to say is both sensible and instructive. Taken with due allowance for the dilemma above referred to, a good deal may be learnt from the report, and it is highly encouraging. In that department of electric lighting Mr. Edison is doing excellent work in this country and on the Continent, where we heartily wish he may achieve all the success he seems to anticipate. What he has said is certainly calculated to reassure at least one class of the investing public, and to reinstate him in the confidence of the European public generally.

THE TRANSMISSION OF POWER BY MEANS OF ELECTRICITY.*

M. Marcel Deprez has sent to the Academy of Sciences the following translation of the official report of the committee of the Munich Electric Exhibition on the experiments made on and after the 26th September, 1882, concerning the transmission of power by dynamo-electric machines:—

"By means of two dynamo-electric machines (Gramme system) of identically similar make M. Marcel Deprez has transto Munich (over a distance of 57 kilometres) along an ironmitted telegraph wire of 4·5 millimetres diameter the power obtained at Miesbach from a steam engine. The receiving machine placed in the Crystal Palace supplied motive power during eight days to a centrifugal pump feeding a small waterfall of about 2·5 metres in height. The dynamo-electric machines were set in motion for the first time on Sept. 25th, at 7 p.m., and according to the data of M. Datterer, an engineer appointed by the committee, the receiver placed at Munich rotated at a speed of 1,500 revolutions per minute; the brake used to measure the work was loaded with 1·5 kilograms.

"A series of accidents, due to the fact that the machines were made for laboratory experiments and not for practical work, put a stop, at the end of eight days, to the till then entirely satisfactory working of the machines. The hoops which surrounded the ring of one of the machines broke; owing to this, the wires of the ring, ·4 millimetre in diameter, were injured and had to be re-insulated. In the small town far away from Miesbach these repairs could only be carried out under great difficulties, and necessitated much patience and perseverance on the part of M. Marcel Deprez's assistants.

"On the 9th and 10th October, when the Experiment Committee began to take measurements, a speed of only 1,600 revolutions per minute could be reached with the machine that had been repaired at Miesbach; the results obtained were, therefore, far less favourable than they would have been with the normal speed of 2,000 revolutions obtained at first. For some moments only during the measurements could the speed of 2,000 revolutions per minute be obtained, and, again, at the commencement of the experiments one of the brushes of the machine came off, which produced an extra current, and completely destroyed the machine.

"The results obtained under these unfavourable circumstances, under the direction of Professors Dorn, Kittler, Pfeiffer, and Schröter were as follow:—

	Ohms.
Resistance of the line	950·2
Resistance of the machine at Miesbach	453·1
Resistance of the machine at Munich.....	453·4

"The only experiment which need be mentioned lasted five minutes, on the 10th of October, between 12:32 and 12:37. The number of revolutions per minute of the machines was at Miesbach 1,611, and at Munich 752; the current at Miesbach was ·519 ampere, and the electromotive force at Munich 850 volts. Summing up, and taking into account the length of the line, but not losses, we have at Miesbach an electromotive force of 1,343 volts, a total electrical work of 1·13 h.-p., work equal to ·680 h.-p. expended in the circuit in heating, and ·433 h.-p. at disposal for the transmission of a power which is equal to 38·9 per cent. of the total electrical work. The direct estimation of the effective work, undertaken at the same time as the electrical measurements, did not give any exact result; in the first place, the Munich machine had not a sufficiently solid foundation, and part of the work was absorbed by the vibrations of the machine; secondly, the Hefner-Alteneck dynamometer, used at Miesbach, was constructed to measure from 15 h.-p. upwards, and the limits of error of this apparatus were too large for the small power required to be measured. The work obtained at the brake at Munich rose to ·25 h.-p.; to this should be added the work absorbed by the vibrations of the machine. In the place of direct measurements a more exact value of the work expended at Miesbach will be arrived at by reckoning the electrical work expended at Miesbach and the return from the machine at Munich, which was identical with that at Miesbach, a return which can be estimated by the figures given above, taking into account the vibrations.

"As, owing to the numerous accidents indicated above, the results obtained during the measurements made by the Experiment Committee were much less favourable than those made during the first experiments, M. Marcel Deprez has decided to repeat the experiment at Munich, with more solidly made machines*, and then only, we think, can a decisive judgment be given as to the return. Meanwhile, we do not hesitate to proclaim the success of the transmission of power from Miesbach to Munich as in every way an important event in the history of the technical applications of electricity."

M. Marcel Deprez has taken upon himself to consider that the criticisms of his compatriots were not serious, and were inspired by a feeling of envy. We attach no importance to this reproach from the inventor, who has no one to blame but himself for the smallness of his results. The Miesbach-Munich experiments have been impartially judged in other countries besides France, and we know no better way of proving this than by reproducing the opinion of a German paper, the *Centralblatt für Electrotechnik*. Our contemporary says:—

"The author of the report on the Exhibition at Munich,

* Official Report of the Committee of the Munich Electric Exhibition on M. Marcel Deprez's Experiments between Miesbach and Munich, with additional matter. Translated from *L'Electricien* for March 1, 1883.

* Our readers will be aware that the experiment was repeated at Paris the other day, as announced in our notes, *vide Electrician*, March 3, p. 361; Feb. 24, p. 339; Feb. 17, p. 314; and Feb. 10, p. 291.

Digitized by Google

after having cited an instance of the transmission of power by means of two Schuckert machines, type T L_4 and T L_5, in which the return was nearly 36 per cent., criticises the Miesbach-Munich experiment. The resistance of the line (two wires of 4·5 millimetres diameter each) was estimated at 950 ohms, and the loss of electricity at 3 per cent. This was owing to the fact that the wire could not be perfectly insulated. The two Gramme machines each had a resistance of 470 ohms; the total resistance of the circuit was, therefore, 1,890 ohms. The speed at Miesbach was 2,200 revolutions per minute, and at the Crystal Palace, Munich, 1,500 revolutions. From this M. Deprez reckoned that the useful effect should exceed 60 per cent., for, according to a known theory, this effect is obtained by the relation between the speeds

$$\frac{1500}{2200} = 68 \text{ per cent., about.}$$

"Now, this theory would not hold, because it supposes the machines perfectly insulated and a line without loss, which has not yet been realised, above all with machines working at high electromotive forces. For instance, in transmitting power at Montceau-les-Mines, the receiver revolved at a quicker rate than the generator, from which it follows that the return ought to have exceeded 100 per cent., a result which even M. Deprez would not care to admit. Further, this theory only gives an approximate value for the return, even with perfectly insulated machines." Further on the author adds, "Dr. Kittler has furnished us with the following figures relating to the Miesbach experiment:—

Current at Munich	·5 ampere.
Electromotive force of machine	850 volts.
Resistance of machine.....	470 ohms.

"The loss of electromotive force inside the machine was, therefore, 470 ohms × ·5 ampere, or 235 volts. We have left 615 volts, from which we get a theoretical effect in kilogrammetres, represented by

$$\frac{C\,E}{9{\cdot}81} = \frac{{\cdot}5 \times 615}{9{\cdot}81} = 31{\cdot}3,$$

whilst M. Deprez asserts that he measured 38 with a Prony brake. If, now, we value at 8 per cent. the loss of electricity due to the magnetic work, to friction, and to Foucault currents, this figure will not be too high, having regard to the speed of 1,500 revolutions per minute; the value given above is reduced to about 28·8. Let us follow out these calculations. The power, expressed in volt-amperes, is, for the generator,

$$E_g = 850 \text{ volts} \times {\cdot}5 \text{ ampere} = 425 \text{ volt-amperes.}$$

"If we remember that the loss on the line was 3 per cent., and the current at Munich ·5 ampere, the current at Miesbach should have been ·515. Let us consider one of the two lines, and take on this line a point the distance of which corresponds to a resistance w. For a variation dw of this resistance, the variation of the power will be:—

$$dE_l = C^2\,dw. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$\text{now, } C = {\cdot}5 + \frac{w}{475} \times {\cdot}015. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

In fact, 475 or $\frac{950}{2}$ is the resistance of each of the two lines, since the total resistance of the double line is 950 ohms.

"Integrating, we get

$$E_l = 2\int_{w=0}^{w=475} ({\cdot}5 + \frac{{\cdot}015}{475}\,w)^2\,dw; \quad . \quad . \quad . \quad (3)$$

or,

$$E_l = 2\left[\frac{(·5 + \frac{·015}{475}\,w)^3}{3 \times \frac{·015}{475}}\right]_{w=0}^{w=475}$$

"We thus find

$$E_l = 244{\cdot}9 \text{ volt-amperes.}$$

Now we have only to carry out the calculations as regards the receiver. We see at once that

$$E_r = ({\cdot}515)^2 \times 470 = 124{\cdot}6 \text{ volt-amperes.}$$

From which, then, we get by summing up

$$E_g = 425$$
$$E_l = 244{\cdot}9$$
$$E_r = 124{\cdot}6$$
$$E = 794{\cdot}5 \text{ volt-amperes.}$$

"If, then, we value the loss due to magnetic work, Foucault currents, and in the circuit, at 10 per cent., a figure which the speed of 2,200 revolutions amply justifies, the result should be increased to 874 volt-amperes, or 89·1 kilogrammetres. The ratio then is $\frac{31{\cdot}3}{89{\cdot}1} = 35$ per cent.

"It remains for us to remark that the differences of potential at the terminals of the machines in the Miesbach-Munich experiment are so large that they render very serious accidents both possible and easy."

The author protests against the custom of attributing to M. Marcel Deprez "a theory of the transmission of power to a distance." He affirms that people knew long before him that the useful effect could be considerably increased by using very large resistances. We can *theoretically* obtain, says he, by presupposing a perfectly insulated system, and neglecting the losses due to Foucault currents and other causes, a return of cent. per cent. "Only," he adds, "however well the system may be insulated, the loss increases very rapidly when the resistances and electromotive forces increase, and the danger of working the machines becomes so great that one must be foolhardy to attempt to transmit power under such conditions."

LITERATURE.

Elements of Construction for Electro-magnets. By Count Th. Du Moncel. Translated by Mr. C. J. Wharton. London: E. and F. N. Spon.

We are glad to welcome an English version of this little work. The translation by Mr. C. J. Wharton has been carried out in an able manner, and he has given an opportunity to many of reading a work which otherwise they could not do. In noticing the French edition of the work, we hinted that it was one that all students should read. It is upon a subject that has not proved very attractive to English investigators, and, as the preface of this work says, "further experiments would be of great advantage." The translator has been requested by Count du Moncel "to explain that the experiments undertaken by him in order to determine the ratios of magnetic moment for the standard electro-magnet have not been numerous and varied enough for them to be taken as presenting great exactitude. . . . What, however, may be taken as certain is that electro-magnets constructed and used in accordance with his formulas are employed in the most advantageous manner possible." Now, if there is one thing more than another that the practical workers in electric light apparatus do not know, it is the "formulas," &c., relating to electro-magnets. Henceforth there can be no excuse for ignorance, at any rate so far as the information given in this work extends. The get-up of the book, so far as regards printing and arrangement, should commend itself, and we hope it will meet with the success it deserves.

A Memorial to Morse.—News from Rome states that on Monday last a commemorative stone was placed on the house No. 17 in Via Dei Prefetti to Morse, the telegraphist. The inscription is as follows, translated into English:—"Samuel Finkez Breese Morse inhabited this house from 20th February, 1830, to January, 1831, inventor of the writing electro-magnetic telegraph. He was born at Charlestown 27th April, 1791; died at New York 2nd April, 1872."

THE BOARD OF TRADE "DRAFT CLAUSES."

In our last issue we gave the memorandum attached to these clauses. The memorandum gives a general idea of the main point aimed at by the clauses. We shall now refer more directly to the clauses themselves.

Preliminary.—These clauses deal with the interpretation of the Act, and define the meaning of "main," "service line," "charging main," distributing main," "general supply," "Schedule A," &c.

Area of Supply (as regards local authorities).—The order is supposed to refer to two areas—a small one A, included in a larger area B. Any part or parts of area B may be added to area A on application of the undertakers any time after the commencement of the order. After two years any fifty owners or occupiers in area B within a quarter mile radius may on application have the area represented by them added to area of supply.

Area of Supply (as regards a company).—These clauses are similar to the foregoing, except that the local authorities have to be duly notified of alterations, &c.

Capital.—Within six months after commencement of order the capital is to be ready, and a deposit made of a certain part of the capital, or otherwise satisfy the Board of Trade. The capital is to be such as seems reasonably sufficient for the supply of area A, and the amount to be deposited is one-half the amount required to execute the works in area A. Failure may lead to the cancelment of the order. The time (six months) may be extended. When the area is extended the capital is to be increased, and a deposit made, within six months. The capital is to be retained by the undertakers for the purpose for which it was originally raised, except by approval of the Board of Trade.

Nature and Mode of Supply.—The "parallel" system is the system to be used, except under approval of the Board of Trade, when the "series," or any other system, may be used. Notice is to be given to local authority two weeks before commencing to supply.

Works.—These clauses refer to erection of distributing boxes of approved construction, to notices, and plans required before interference with streets, &c., to the power local authorities shall have over the work of breaking up the streets, &c., and the perils of default.

Compulsory Work.—The streets specified in area A are to be supplied within two years after commencement of order, and other streets that shall be added to above in the manner specified by the order to be supplied within six months of requisition. Similarly with the streets, &c., in area B. The requisitionists are required to agree to take for a period of three years at least such specified amount of electricity respectively as will in the aggregate at the rate of charge for the time being charged by the undertakers for a supply of electricity from distributing mains to ordinary consumers within the area of supply produce an annual sum amounting to not less than twenty per centum upon the expense of providing and laying down such distributing mains and any other mains which may be necessary for the purpose of connecting such distributing mains with the nearest source of supply.

Maps.—These clauses refer to maps and plans to be supplied, made public, &c.

Regulations as to Supply on the Parallel System.—The supply to be constant at a given pressure (E.M.F.) after six months from commencement of order. Except at times approved by Board of Trade, such intervals being required for testing, &c. The difference in potential not to vary at any point more than 5 per cent. from the standard pressure.

"The standard pressure may be different for different points of any main, and for different hours during the period of supply, but it shall in all cases be within the limits following:—

"In the case of continuous currents it shall not be less than thirty volts, or more than two hundred volts, and

"In the case of alterating currents it shall not be less than fifty volts, or more than one hundred volts, the difference of potential being measured by its maximum value during a complete alternation."

The standard pressure to be fixed for every main and notice given of alteration, which cannot be made without permission. The number of alternations per minute to be not less than 600, or such other number as agreed upon. The supply, to be given to consumer from two poles, up to 50 volts. The undertakers' liabilities end at the poles, and the resistance of the consumers' lines to be such as will not reduce potential more than 2½ per cent.

Testing.—A number of clauses refer to testing, to expenses of testing, &c.

Supply.—These clauses refer to efficiency, compulsory supply, and penalties.

Price.—Charge may be made (except by agreement).

1. By the quantity of energy contained in the supply.
2. By the actual quantity of electricity so supplied, or, unless the Board of Trade from time to time otherwise direct.
3. By the number of hours during which the supply of electricity is actually used by such consumer, and the maximum current with which he has required to be supplied.

Certain notices relating to method of charge adopted must be given, and a maximum price stated, &c.

Meters.—These clauses relate to hire, purchase, connection, testing, &c. of meters.

Regulations as to Safety.—Mains and service lines shall be of a pattern to be approved of by the Board of Trade, and shall be covered with thoroughly waterproof covering, and be contained in pipes or cases of sufficient strength to protect them from injury, and due precautions shall be taken to prevent any insulating material which may be used being rendered plastic or being otherwise injured by the action of external heat. The insulation to be of a durable character, with a resistance of not less than 1,000 ohms per mile run, or such other amount as may from time to time be described by any regulations of the Board of Trade. No conductor in any part of any circuit shall be connected with earth unless such connection is sanctioned by the Board of Trade. The current through any service line shall not exceed —— amperes per square inch of section of a pure copper wire of equal conductivity. The supply of electricity to each house shall be capable of being turned off at some point outside the building. In each conductor of each service line shall be inserted a safety fuse or other safety connection of a pattern to be approved by the Board of Trade. Such fuse or connection shall be situated in a distributing box or at some other point in the service line which is easily accessible, and shall be of such a nature as to cut off the supply when the current through such conductor exceeds by more than 100 per cent. (or such other smaller proportion as the undertakers may think fit) the maximum current which such service line is intended to supply. The positive and negative poles upon the premises of the consumer shall be at a distance of not less than 3in., and the terminals shall be of a construction and pattern to be approved of by the Board of Trade, and no portion of any service line which may be upon the premises of any consumer shall contain any joint between the point at which it enters upon the said premises and the said poles. Where the maximum current given to any consumer upon the parallel system exceeds fifty amperes, the supply shall be divided and given at more than one pair of poles, so that the maximum current at each pair of poles shall not exceed fifty amperes except in such cases and under such conditions as may be approved of by the Board of Trade. Where the difference of potential between any point of any main or electric line used by the undertakers and the earth, or between such point and any other point upon the same circuit exceeds 200 volts, such precaution shall be taken by the undertakers as may from time to time be prescribed by the Board of Trade to prevent such main or electric line becoming electrically connected with or leaking into any main or electric line through which electricity passes at a different potential. Where the difference of potential between any point of any charging main and the earth or between such point and any other point upon the same circuit exceeds two hundred volts, all distributing mains connected therewith shall be fitted with such appliances and apparatus of such pattern and construction as may be from time to time prescribed or approved of by the Board of Trade for the purpose of ensuring that such mains shall be effectively disconnected and kept disconnected from such batteries during the hours of charging. No portion of any electric line which may be placed by the undertakers above ground, and which is not enclosed within any distributing box or building, shall be at a potential differing from that of the earth by more than two hundred volts. Where any portions of any electric lines belonging to the undertakers are exposed in such a position as to be liable to be struck by lightning, they shall be efficiently protected by lightning dischargers of such pattern and contruction as may be from time to time prescribed or approved by the Board of Trade. The difference of potential at corresponding points of the positive and negative conductors used as distributing mains or service lines shall not at any time exceed two hundred volts, and no portion of any such conductor shall be at a potential differing from that of the earth by more than such quantity. The difference of potential at any two points of a charging main shall not exceed four thousand

Digitized by Google

volts, and no portion of any such main shall be at a potential differing from that of the earth by more than such quantity.

Provided always, that if the undertakers at any time desire to supply electricity by agreement at a high tension for the purpose of arc lighting or for any other purpose, the Board of Trade, if they think fit, may relieve the undertakers from all or any of the obligations by this section imposed upon them, and may substitute such other regulations to be observed by the undertakers in relation to such supply as they may think expedient; and all regulations so substituted shall be observed by the undertakers, and shall, for all purposes of enforcement or otherwise, be deemed to have been inserted in this section in lieu of the regulations for which the same are substituted.

EDISON'S VIEWS ON ELECTRIC LIGHTING.*

After remarking on the *Herald* installation, Mr. Edison said:

"It is the lighting simply from an isolated plant—not like lighting from a central plant which supplies a large area with light, like a gas company. What I started to do was to light a whole city, furnish electric light as gas is furnished, and collect and make money on bills running as low as 75 cents a month. In the district we are now lighting we have several consumers whose bills do not amount to more than 1dol. 50c. a month. Our plant at 237, Pearl-street is one of the typical stations by which we propose to light cities. Such stations can be multiplied indefinitely, so that we can engage to light the largest as well as the smallest cities in the world. At this time 289 stores are taking light regularly from us on meter. We have commenced to connect more stores with our mains, and expect to have, by the middle of February, 550 stores lighted from that station. In most of the stores now lighted by us gas has been entirely cut off. Many, indeed, have not been using gas for the past four months. In fact, they depend entirely upon us for their light, and we do not fail them. At first we placed temporary fixtures on their gas chandeliers, but are now gradually changing them over to our electric chandeliers. This looks like permanency, does it not? Well, that is just what it is. We have come to stay. We have 19 miles of street mains and four miles of service pipes, and all our wires are underground. They are carried in iron pipes of twice the thickness of ordinary iron pipes, and coated with asphalte. If, in the course of years, these pipes should rust through, it would not harm us so far as using the wires is concerned, for our wires or rods have a quarter of an inch insulation over them in the pipes."

"How about regulating the supply of electricity according to the needs of consumers?"

"Persons outside who do not understand our system are trying, I know, to make people believe that if we are running, and all the lamps in the circuit are put out, there is at once a loss—a waste of energy. According to our system, if all the lamps in the circuit were put out, the automatic cut-off of the engines causes less steam to be admitted to the cylinder, but sufficient to keep it running. Suppose, for example, a single engine was running and its dynamo connected to the mains and no lamps were being used. The only power required would be to keep the engine running without doing work. If, now, eight lamps are turned on by some consumer, the automatic cut-off of the engine will admit more steam to the cylinder and the engine will give one horse-power in work; if 80 lamps are now connected, more steam is admitted to the cylinder, and the engine gives 10 horse-power; and so on up to the capacity of the engine. The steam dynamos at our station, when working economically, give 185 horse-power. We have six of them. Up to 1,400 lights we use a single steam dynamo. When the consumption exceeds this number of lights we add another dynamo and engine. When the consumption reaches 2,800 lights another is added, and so on—thus each steam engine and dynamo is worked at its most economical point; the number of engines working depend upon the consumption; our greatest consumption is between 5 and 6 p.m., when five engines can be put on, leaving one for a spare, which can instantly be connected to the mains in case of accident to any of the others, but even if the spare engines should become disabled four steam dynamos will carry the load, but not with the same economy as if five were used. Before 5 and after 6 p.m. the consumption is greatly lessened, and there are two or three spare steam dynamos. What I mean by a steam dynamo is where the engine is connected direct to the dynamo without the intervention of pulleys or belts. We have a relay of boilers upon which we can depend to give us all the power needed and meet every emergency. You will understand that we have a large number of consumers, and know from general average pretty accurately what they will demand from us. We can, therefore, tell beforehand what will be the consumption during different hours of the day, which varies with circumstances. If the morning be foggy or dark we start up with two or three boilers. We also have an indicator to tell how much power is required, and, as the load increases, we add more boilers, just as the case with the steam dynamo, disconnecting them as the load diminishes. We started our engine on September 4 last, and since that time the current has never been off the main for a second, night or day."

"What do you think of lighting by the electric arc?"

At this question Mr. Edison smiled contemptuously. He said:—"The arc people get a little place, with a boiler, engine, and a dynamo or two, and then they string their wires like clothes lines, overhead in various directions, connecting with a few lamps here and there, and call that a system of electric lighting. These wires generally break down six or eight times a year, when all the lights go out. No attempt is made toward permanency. They have no means of ascertaining how much electricity is used, but guess at it and trust to luck. That [with emphasis] is not electric lighting. It is nothing but boys' play—a temporary makeshift—an excuse for the creation of a stock corporation with an unknown quantity or possibility as a bait. This stringing wires over houses and along a lot of poles in large cities has a serious side, which is well set forth in an editorial in the *Scientific American* of January 13, under the heading of 'Perils from Suspended Electric Wires.' Let me give you a few extracts:—'The promoters of electric lighting confidently promised at first that the new illuminant would insure complete immunity from the peculiar fire risks and dangers to life and health incident to the use of gas. The promise has been fulfilled; but, unexpectedly, the use of electricity for public lighting has developed a variety of public perils as numerous and serious as any due to illuminating gas, and far more subtle. [This, of course, refers to the arc lighting.] Scarcely a day passes without some new and surprising development of this character. . . . Until the introduction of suspended conductors for the larger current employed in electric lighting, the multitudinous telegraph and telephone wires were no more than harmless offenders against æsthetic propriety. Crossed by electric light conductors, they at once become the means of ever impending fire hazard; for the current diverted by the slightest contact with an electric light conductor suffices to heat the coils of telephones and telegraphic instruments to such a degree as to destroy them, and at the same time set fire to any combustible matter near at hand. But this is not the only peril incident to such contacts. An officer of the fire department of this city reports that, during a recent fire, the assistant foreman of a fire company received a severe shock when he went to re-case the key of a fire-alarm box near the scene of the fire. The inference was that the fire telegraph wire had been accidentally crossed by an electric light wire, and that, had the pavement been damp on which the fireman stood, so as to make good 'ground,' the current passing through his body might have killed him on the spot. Only a few days before, an accidental contact of an electric light wire with a fire service telegraph wire resulted in the destruction of the electro-magnets in a dozen fire-alarm boxes in Nassau, Liberty, Fulton, Beekman, Greenwich, and Hudson-streets. By spoiling the means of instant communication with the fire service, in case a fire should break out, an accident of this nature is obviously a very serious affair. And quite as undesirable as the interruption of the fire alarm service is the development of a feeling among firemen and citizens generally that the legitimate use of an alarm box involves a peril that may be as sudden and deadly as a stroke of lightning. Telegraphic switch-boards and telephonic instruments are similarly made more or less hazardous to use by the same misdirection of electric light currents. Still more recently, at a fire in Fourteenth-street, some broken telegraph wires in front of the building fell across an electric light wire, and became entangled with the firemen's hose. It is probable that the heated telegraph wires burnt through the insulating cover of the electric light wire, so as to establish contact. At any rate, when a fireman went to free the hose from the wires he received a severe shock. Enough of the current of the electric light wire had been diverted through the broken telegraph wires to the ground to make it unpleasant if not dangerous to handle them. . . . With the rapid extension of electric lighting by means of arc lights, the hazard of life and property arising from misdirected currents has suddenly become one of the most serious as well as alarming of city evils. And it is certain that were the community to fully realise the subtlety, pervasiveness, and indeterminableness of the perils arising from vagrant electricity, as it would if each diversion of an electric light current were accompanied, as the not more dangerous light-

ning stroke is, by a peal of thunder, there would arise a speedy and positive demand for the adoption of safer modes of distributing this useful but treacherous agent.' There you have the testimony of a journal which has no interest in any system of electric lighting. Here let me say that the arc light people measure their light by the French method, and claim 2,000 candles, when, as gas is measured, it should only be 500; but, in reality, even if we measure in every direction, it would be only 280 candles. But they find they are losing money, and bring their carbons so near together that they are, in many cases, giving only 100 candles."

"But is not the arc light well adapted for outside illumination?"

"Not by any means; it is not good for any kind of illumination. If it was, it appears to me the Almighty would give us eyes different from those he has bestowed upon us. The arc light is unreliable, to begin with. Its very nature makes it so. It has no diffusive power. Aqueous vapour, as is well known, will absorb the blue, green, and violet rays which make up a white light. It is only the red and yellow rays that will pass through it with facility; of these rays the arc light possesses very little. In a dense fog you cannot, therefore, but just see an arc light, but a gas lamp alongside it can be discerned easily on account of the great volume of red and yellow rays. I wonder your people in Boston have so many arc lights. If the ruse is continued a few years longer the people's eyes must suffer. In Paris, in the Jablochkoff works all the workmen are troubled with sore eyes. It produces a new kind of disease of the eye, the name of which I cannot now recall. Under the influence of such a light, if you watch the contraction and expansion of the eye from the alternate brilliancy or quick alternation to a low power of illumination, you will see what I mean. It is hard to read by gaslight, the flickering of which contracts and expands the pupil of the eye, irritating the visual organ in a most painful manner sometimes. Now, kerosene oil gives a steady light, and it is the same with our incandescent light. I have looked at an arc light, then went into a room lighted by gas, shut my eyes for a moment, opened them, and the pupils expanded a quarter of an inch. Of course some eyes will contract and expand more than others. You can try it yourself by using a small hand mirror and looking on a gaslight and then turning your eyes on the glass, when you can plainly note the contraction and expansion of the pupils, the changes being rapid and marvellous. A light can be very bright, but as long as it is steady it will not change the size of the pupil. Gaslight can never be steady, any more than the arc light. The pressure on gas is so small that the shutting off or turning on of light—which is occurring at all times in a city—causes constant vibrations. Even a gas engine, fed from the general supply, where the consumption is intermittent, produces vibrations all around among the gaslights. Lighting a theatre suddenly will produce a wave of low pressure all around the vicinity, and several oscillations will take place until the wave dies out. A thousand such incidents occur to produce changes in pressure and consequent flickering."

"Will not the incandescent lights act in the same manner if there is a sudden and considerable demand made upon their source of supply?"

"They will respond to such a demand, it is true, but it is only for an instant, and no waves will occur, while, in the case of gas, there is depression, which may last a minute and a half, and there may, in this time, be produced from 20 to 30 oscillations. It is a very difficult thing to distribute gas evenly, and ten times as hard to distribute electricity; but, so far in our district, we have our pressure far more even than the gas men."

"By the way, Mr. Edison, have you ever tried gas as a fuel; for, of course, the matter of economy in this direction is a most important one?"

"I have made, at Menlo Park, during some eight months, many experiments on fuels. Among other things I tried gas, which I made on the spot, and put under the boilers. Gas is a very nice fuel, but not so cheap as from coal direct. It required more ability to produce and use it than coal, and brains now cost more than coal. Perhaps by and by, when brains are cheap and coal scarce, we may find it to our account to use gas as fuel. But, so far, coal is the cheapest. We use a 3dol. coal at our station—peat and dust."

"You, of course, are confident of the success of your system?"

"I started in 1878 to subdivide the electric light and displace gas. The first I accomplished; as to the latter a great deal of talking has been done, but, nevertheless, we are going to do it. It is gradually being done by distributing it in exactly the same way that gas is distributed—that is, from large central stations, with main pipes running through the streets, tapped wherever required, and run into the cellars of houses, the electricity measured to consumers with metres, and that is the only way it will ever be done. You cannot place in the hands of the public any mechanism of a complicated character, and have it prove a success. It must be under the control of those who understand the business. The public have got to pay their bills, and that is all we ask of them. We now know exactly what incandescent lighting costs at the present time. The cost of production and investment required for a given output is being diminished continually. If we start a station in Boston we shall sell light at the same price as we do in New York, which is about the price of gas."

"Can you make money at it?"

"Yes, we can, and are doing it in the present state of the act, and, in addition, the margin for improvement is infinitely greater than it is with gas. In 1878 people said the subdivision of the electric light was impracticable—could not be done. Now we are doing it upon a commercial scale, and are not losing money. If this has been accomplished in four years, why cannot still further improvements be made to the end of materially reducing the cost of production? Of course they can, and if, by such improvements, we can produce the electric light at less cost than at present the public will get one-half the benefit ('if our stockholders feel like it') and we the other half. As it is we, do not find that it is even necessary to come down to the exact level of gas, as people are willing to pay more for our light than gaslight. I consider from experience gained thus far that a unit of light by electricity has a commercial value 33 per cent. above that of gas, as gas is above kerosene, and, if we desired, we can get 33 per cent. more for the same unit of light over and above gas, as people are willing to pay more for the same amount, but of a better quality. They will pay 2dols. 25c. for gas for the same amount of light they can get in kerosene for 60c. Men will sometimes get excited over their gas bills, put out the gas and use kerosene; but they will inevitably return to gas. We have had an experience of that kind. One of our customers thought he was paying too much for his light, and we cut him off; but in two or three days he came to us and wanted it put back. Following the subject of the relative cost of gas and electricity we have made photometrical measurements of gas under every variety of conditions in New York city, and find that the average amount of standard candles of light obtained in practice from the consumption of 1,000 cubic feet of gas is 2,000 standard candles. Buy 1,000 cubic feet of the gas sold by the Boston Gas Light Company, burn it in the burners that are used in practice, and you will not get more than 2,000 standard candles. At the city gas testing department, with a definite pressure, a new and perfect burner, made expressly for the quality of gas, and nursed by a skilled expert, 1,000 cubic feet of Boston gas would give 3,200 standard candles. But, in actual practice, there are burners of all kinds, old and new. The pressure of the gas on the mains varies in every part of the city; it is, besides, constantly altering in different localities by varying consumption; hence, if new burners were used, the variations of pressure would diminish the amount of light, and the burners, after a few weeks' use, would, by deposition of matter within the slit of the burners in different degrees, give all kinds of candle power. I will give you an instance. About a year ago you will remember that I kept promising, through the newspapers, that the large central station in New York would be started at such and such a time (these many promises, by the way, were made more with a view to keep up the courage of my stockholders, who naturally want to get rich faster than the nature of things will permit), and, having failed to start upon several of the dates named, the gas companies operating in the district in which our mains were laid concluded that on one of my dates I would certainly start, whereupon we sent emissaries around and provided all of their consumers with new burners free of charge, to the end that a more favourable comparison could be made. These burners, from tests made by me at several points, gave 2,700 candles per 1,000ft. of gas consumed. The station was not started until two months after this had been done. The burners had so deteriorated during this interval, that three days after starting our station the same burner only gave 2,300 standard candles, and, I presume, by this time they do not give more than 2,000 candles. This is a thing that can easily be verified. It is not a difficult matter to determine the relative cost of both kinds of light at your *Herald* Office. Knowing the cost of gas, then make a rough mental calculation what the electric light would cost from a great central plant supplying 50,000 lights. Some people are continually chattering about the cost of electric lighting, that it cannot be made as cheap as gas, &c. If, in answer to these people, I show that it is possible, and that it is an exceedingly profitable business when done on a large scale, the public would be dissatisfied to pay the price we sell it for. On the other hand, if I say we can just compete with gas, and have to sell it for about the same, then the investing public will put no money into it. So, you see, I am in a dilemma about making statements as to cost."

THE INSTITUTION OF CIVIL ENGINEERS.

The second of the series of six lectures on the applications of electricity was delivered on Thursday evening, the 1st of March, by Sir Frederick Bramwell, F.R.S., V.P. Inst. C.E., the subject being "Telephones." The following is an abstract of the lecture:—

Prior to the invention of the telephone, by making and breaking circuit at the transmitting station sounds had been produced at the receiving station—such as the striking of bells, or the vibration of a Morse sounder—but these were independent of sound at the transmitting station, and they varied according to the implement used at the receiving station, and were and are used for purposes of audible telegraphy. Also, prior to the invention of the telephone, it was possible to reproduce at the receiving station, say by a tuning-fork, the vibrations of which break and make contact, the same note produced by a similar tuning-fork at the transmitting station; and in this case there was a reproduction at the receiving station of the sound at the transmitting station. But the only thing that was ensured was the repetition of the same note—there was no reproduction of the same sound. For example, the note might have been uttered by a violin string, by a tuning-fork, or by a clarionet at the transmitting station; at the receiving station, however, nothing would be given forth but the note of the particular tuning-fork, or other vibrating implement, which was in accord with the number of the vibrations transmitted in a given time. All these modes were due to the variations of the current caused by break and make in the circuit, and were therefore abrupt. The best result obtained with such an agency was in the machine of Reis, who, in 1862, reproduced tones, and it is said some words were heard. That machine received no development, and telephony lay dormant for fourteen years, until the invention of Professor Graham Bell, patented in this country in December, 1876. In 1874 Mr. William Henry Barlow, F.R.S., Past-President Inst. C.E., turned his attention to the recording of the vibrations produced by speech. He effected this by means of an instrument called a logograph. This was communicated to the Royal Society, and exhibited in operation there. By its agency there was depicted on a travelling band of paper the motions derived from the vibration of a membrane under the influence of speech; but had the results been known, they would, probably, have deterred an inventor seeking to produce a telephone, as it appeared the vibrations were not always the same for the same syllable, but varied with the speaker and from the circumstances. Professor Graham Bell graphically represented the variations in the electric current, either direct or reversed, caused by break and make, and showed that these were too abrupt for his purpose—namely, the reproduction of articulate speech. He proposed to attain the object sought by having the circuit always closed, and by causing rises and falls, or reversals, as the case might be, of electricity which should be made gradually, instead of abruptly, as before. The simplest mode in which he attained this end was in one of the original forms of the Bell Transmitter or receiver (for the instrument was capable of fulfilling either function) by placing an iron or a steel plate in the neighbourhood of a permanent magnet surrounded by a coil of insulated wire, so that on the plate being set into vibration by the voice it should induce, in the coil, reversed currents of electricity which could travel along the wire in prolongation of the coil to the coil of the similar instrument at the receiving station, thereby varying the power of the magnet at that station and setting up vibrations in the corresponding iron disc. This disc, acting upon the air, gave to it vibrations similar to those which had put the first disc into motion, and, in that way, a reproduction of the original sound (as Professor Bell said a *fac simile*) was obtained. Other modes were employed by him, such as the use of a battery in the line-wire, and best of all, the use of two local batteries to send the current to a primary coil round a core, the line-wire being connected with secondary coils acting by induced electricity. As transmitters these instruments were necessarily somewhat feeble, since the whole of the electricity in the first of the three cases mentioned, and what might be called the operative electricity in the other two cases, had to be derived from the microscopic movements of the disc, under the influence of the sound-waves produced by the speaker.

Edison's phonograph was exhibited, in order to show that a disc, when caused to vibrate under speech, could by a central needle impress those vibrations on tin foil, and that on the tin foil being caused to traverse under the needle, the reproduction on the disc of those vibrations caused it to repeat the speech which had originally set the disc into motion. This was appealed to as a convincing proof that a disc, when mechanically vibrated in a manner corresponding to the vibrations which had been imparted to it by speech, was sufficient, wholly irrespective of any electrical agency, to impress upon the air the needful vibrations to reproduce speech.

Edison then devised a transmitter, wherein the disc need not be metallic, but might be mica, and its vibrations were caused to operate upon a small block of carbon, which carbon was introduced in the circuit of a battery. It was thus found that the almost inappreciable variation in pressure due to the vibration of the disc was sufficient, for some not very well understood reason, to alter the conducting power of the carbon, and to cause varying currents to be transmitted along the line-wire to the Bell receiver at the opposite end. At the present day the universal transmitting instrument for commercial purposes is the carbon transmitter of Edison or some modification thereof.

Professor Hughes's microphone was next alluded to, and it was stated how by its means the most minute sounds were rendered audible, and how, from the delicacy of the instrument, it was applicable to many scientific purposes.

Edison's chalk receiver was subsequently explained. Prior to Edison's time, it had been known that the friction of certain surfaces varied with the electric current passing through them, notably under such circumstances, the friction of the human tissue. Among other appropriate substances prepared chalk was one, and it was shown how Edison availed himself of this. By attaching a stem to the centre of the disc, and pressing this stem, by means of an adjustable pressure, upon the periphery of a chalk cylinder, a current of electricity passed from the centre of the cylinder through the stem. Upon the cylinder being turned by hand the friction on the stem caused it to move the centre of the disc—its edge being fixed—to a definite position depending on the friction, and on the rigidity of the disc; but, on a variation in the current, the change produced thereby in the friction caused the stem either to be drawn in further or to yield to the elasticity of the disc and to allow it to be moved backwards. In this manner vibrations were set up in the disc corresponding with the vibrations of the transmitter that had sent the varying electrical currents. As in the case of this receiver the power was derived, not from the electricity, but from the hand of the operator turning the chalk cylinder, very considerable loudness was obtained, so that the utterances of the receiver were audible in a large room.

Mr. Shelford Bidwell having been good enough to lend a photophone, that beautiful invention of Professor Graham Bell was explained. Mr. Bidwell showed how, by speaking to a disc, the front being a mirror, on which a powerful light was directed, that light could be reflected on to a selenium cell, and as the disc vibrated under the influence of the voice the light playing on the selenium cell varied. Selenium was a material the conductivity of which changed with the amount of light upon it. It was, therefore, possible in this manner to cause a Bell receiver to speak, and reproduce the speech which had been uttered to the mirror disc. It was pointed out that, in this manner, there was no need of a wire connection between the transmitter and the receiver, the passage of a beam of light being all that was required.

Reference was then made to the various purposes to which the telephone might be put, and to the exchange system and the necessary apparatus for receiving the calls and making the connections between the different subscribers to the exchange. Amongst special uses, a very interesting one was shown—that of the application of telephony to the diver's helmet. Thanks to the kindness of the captain of H.M.S. "Vernon" and of Mr. Gorman, a helmet with the whole of the apparatus was exhibited. It was shown how the application of the telephone in no way introduced any complication, as the single wire needed was in the middle of the old call rope, the return being made by the water itself. Thus, if the telephone went wrong, the diver was left without additional apparatus of any kind to encumber him, and yet with all the resources that he would have had in the absence of the telephone.

It was stated that the development of the telephone had been far more rapid in America than in England. As an instance, it was mentioned that in the City of Washington, with a population of about 120,000 white persons, as many as 800 telephones were used. Then, a return, circulated that very day by the United Telephone Company, was read, showing that on the 28th of February, in the year 1881, there were, independent of private lines, 845 subscribers to the London Exchange; that on the same day in 1882 the number had increased to 1,505—or an addition of 660; and on the 28th of February this year the number was 2,541, or an addition of 1,036; and that contemporaneously with these increases the use of the telephone by each subscriber had augmented, until it now reached more than 7½ calls per day for each subscriber, which, at a cost of £20 a year, represented only twopence a call; or, bearing in mind that each

Digitized by Google

call involved a return message, it only amounted to one penny for the message sent each way.

The lecturer was fortunate in having the assistance of Mr. E. H. Johnson, who had been so much associated with Mr. Edison in carrying out many of his inventions, and who was kind enough to put into work both the phonograph and the chalk receiver.

The third lecture of the series will be on "The Electrical Transmission and Storage of Power," by Dr. C. William Siemens, F.R.S., M. Inst. C.E. This is to be delivered on the 15th of March.

ELECTRIC LIGHTING AND LOCOMOTION.*

(CONCLUDED FROM PAGE 357.)

[In that portion of Prof. Ayrton's lecture which we printed in our issue of Feb. 24 reference was made to an obliquely coiled dynamo which Prof. Perry and the lecturer had designed. We now give illustrations, showing the mode of winding the armature of this dynamo, as well as other details, which are sufficiently explained by the three figures which follow.]

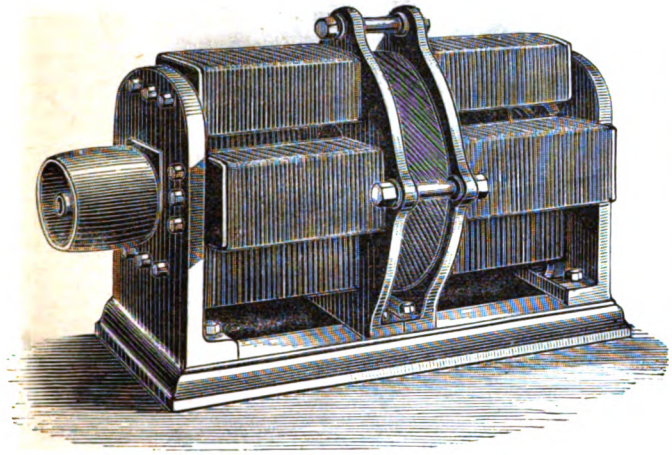

FIG. 1.—Ayrton and Perry's Oblique Coiled Dynamo.

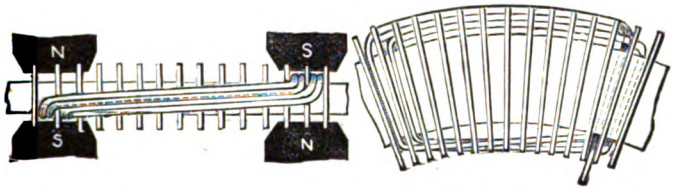

FIG. 2.—Plan and Elevation of portion of Armature

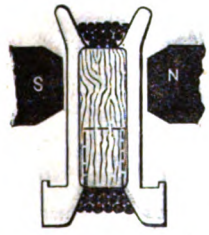

FIG. 3.—Section of Armature of Oblique Coiled Dynamo.

Two of the methods that have been devised to regulate the supply of electric energy in proportion to the demand appear to me to have all the defects of the automatic regulator at the gasworks in that they are far too sluggish. In the one plan, when the dynamo is producing less than the required amount of electric energy, so that in the parallel system the electromotive force between the main leads falls below the normal amount, or the current in the series system becomes less than the normal current, an electro-magnet is partially demagnetised, which has the effect of opening the throttle valve of the steam engine, or altering the expansion, so that the steam engine, and, therefore, the generator-dynamo, goes more quickly than before. But as it is quite possible to start a motor, or turn on a lamp, or many lamps, somewhere in the circuit instantaneously, whereas it is impossible to suddenly either increase or diminish the speed of an engine and dynamo, the regulation in such a system is always considerably behind the change calling it forth,

In the second system no alteration is made either in the speed of the engine or dynamo, but a resistance is withdrawn from the main circuit or from the circuit of the exciting magnets of the dynamo; when the supply of electric energy falls below the demand, the dynamo, in fact, is made more powerful. [A large design showing one of the plans employed by Edison for effecting this latter object was exhibited.]

This plan of introducing a resistance is far better than the former, by which it was attempted to slow both the driving engine and dynamo, in that there is no large mass like that of the engine, the speed of which has to be suddenly changed; but it has the disadvantage that at any rate some mechanism has to be set in motion to vary the resistance, and this requires some time to effect, not to mention the difficulty of producing perfect dead-beatness in the mechanism to avoid oscillations. Also, if the exciting magnets of a dynamo are very powerful, as in the Edison machine, their strength cannot be suddenly altered by altering the strength of the current flowing round them. Hence, with this plan, again, there is a fear that the regulation may be behind the change calling it forth.

There exists, however, a third and totally different plan for governing dynamos, not depending at all on the motion of any electro-magnet, nor on anything like a mechanical governor, and which is extremely quick in its action. This third plan has been carried out in three totally distinct ways—1st, by Brush, in America; 2nd, by Deprez, in France; 3rd, by Professor Perry and myself, in England.

I have said that in any machine for the mechanical production of an electric current a coil of wire must be moved rapidly in a magnetic field. Now, there are four distinct ways in which the magnetic field may be produced—1st, by a permanent magnet, in which case the generator is a "magneto-electric machine;" 2nd, by an electro-magnet, the current flowing round which is produced by an auxiliary battery or electric generator (such a machine is said to be "separately excited); 3rd, by an electro-magnet, the current flowing round which is the main current produced by the generator itself, in which case the generator is a "series or single-circuit dynamo." And lastly, only a portion of the current generated in the moving coil may pass round the electro-magnet, in which case the generator is called a "shunt dynamo." In the two first cases, the magneto-electric machine and separately excited generator, the electromotive force depends almost entirely on the speed of motion and only slightly on the current; while in the third case it increases, and in the fourth case diminishes, with the strength of the current produced when the speed of motion remains constant.

The method employed by Brush consists in doubly winding the exciting magnets, so that the machine is both a series and a shunt dynamo. Deprez also doubly winds the exciting magnets, so that his machine partly magnetises itself, and partly is separately excited from an auxiliary dynamo. In which case two magnetic fields helping one another are produced by this double winding, and dynamos as ordinarily constructed cannot be thus governed without being rewound; further, if a number of dynamos in the same building are to be governed, each must be doubly wound in the manner described.

(The lecturer here described Ayrton and Perry's mode of joining up so as to obtain constant difference of potentials between the mains.)

When we had the lamp and motor in parallel, why was it that the lamp burnt well when the motor was stopped, but only gave a feeble light when the motor was running? Was this due to the electromotive force of the battery diminishing when the motor ran? No; the electromotive force is constant, but a certain portion of this electromotive force is always being employed in sending the current through the battery itself, and the remainder only is available for sending the current through the external resistance, and the proportion of the latter to the whole electromotive force diminishes as the current sent by the particular battery increases.

As long, however, as the resistance of the battery is small compared with that of the external resistance, the current passing through any one lamp is not affected by the number of lamps put in parallel. For example, these two Grove cells make this one lamp glow, so also do they equally well make these three lamps in parallel, because in each case the resistance of the battery is less than that of the lamps. But if I put 20 such lamps in parallel, you observe only a faint glimmer. [Experiment shown.] Let me now repeat this experiment, using in the place of two Grove cells two Faure-Sellon-Volckmar accumulators, and what is the result? You observe I can increase the number of the lamps from one up to 20 in parallel without seriously diminishing the glow in any one of them. [Experiment shown.] If, then, we could have a magneto-electric machine with an armature possessing an excessively small resistance, but producing a sufficiently high electromotive force, one lamp or a hundred could be lighted equally well if the speed of the machine were kept constant—that is to say, the supply of power necessary to keep the speed constant would always be exactly equal to the demand for power necessary to keep any number of lamps equally bright. But, in the absence of such extremely small resistance magneto machines, we must resort to some device to cause one lamp or a hundred lamps to burn equally bright, and the device Professor Perry and I have adopted for the multiple arc system is the combination of a large magneto machine, or main shunt dynamo, which does all the external work, and a small regulating series dynamo which does all the internal work—that is, sends the current through the dynamos itself. In fact, our combination produces the same result as if the resistance of the armature of the larger machine could be made nought without diminishing the electromotive force it can generate.

The speed of the magneto machine or of the main shunt dynamo merely depends on the type of lamp employed, and is such that if it were used *alone* with only one or two lamps, it would produce a difference of potentials between the brushes just sufficient to make the lamps glow properly. The speed of the small governing series dynamo has nothing to do with the lamps; in fact, must be kept quite the same whatever kind of lamps or number of them are employed. The speed of this governing dynamo is what is called the "critical" speed for an external resistance equal to that possessed by the armature of the main magneto or dynamo machine, and which means the speed a little below which the series dynamo would give an extremely small current and a little above which it would give a very great current, if the external resistance were kept constant and equal to that of the armature of the main dynamo—that is, if the external circuit were short-circuited.

This critical speed, which was first suggested by Sir Wm. Thomson, in the earliest days of dynamo machines, in a paper called "An Electrical Paradox," is of the greatest importance to us electrical engineers for governing, since it enables a very slight change of speed to convert a very weak generator into an enormously powerful one, corresponding in steam

* Lecture I., delivered by Professor Ayrton, F.R.S., at the London Institution, February 22, 1883.

Digitized by Google

engines with a very great change in the supply of steam for an extremely small change in the speed, the result aimed at in any good loaded governor for a steam engine.

(The lecturer here described Ayrton and Perry's mode of connecting up for a constant current.)

In the admirable Cantor lectures recently given at the Society of Arts by Professor Silvanus Thompson, the methods employed by Professor Perry and myself for regulating difference of potentials and current were gone into far more fully than I can do here in a popular lecture, and as doubtless many among you who are electrically inclined will read those lectures with interest, Professor Thompson will, I am sure, pardon my giving you a word of warning about the diagrams accompanying his description, since, from some oversight, probably on the draughtsman's part, they do not represent correctly the relative dimensions of our main and regulating machines in each case. This, however, I have endeavoured to do in the symbolical diagrams shown at this lecture.

Up to the present time whenever it has been necessary to convert electric energy into mechanical energy, use has been made of a dynamo worked backwards. But a dynamo is designed for converting mechanical energy

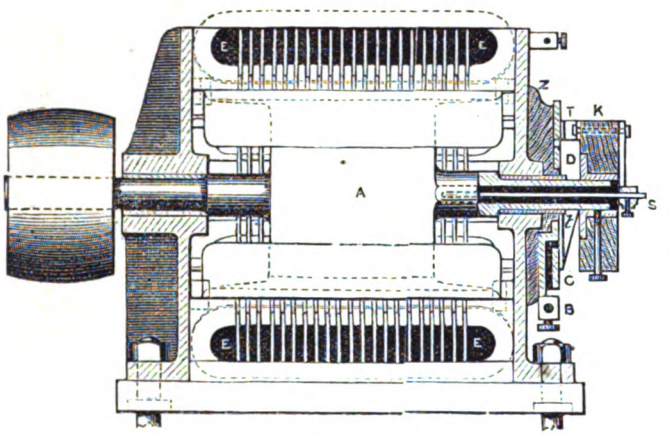

FIG. 4.—Ayrton and Perry's Electro-motor. Longitudinal Section.

into electrical energy, and not to do the converse, therefore, although every dynamo will act as a motor, Professor Perry and myself have come to the conclusion that for its weight it is by no means the most powerful motor that can be designed. In a dynamo there is, as you all know, a large electro-magnet, which produces what is termed the exciting field and a moving armature, the current flowing through which produces another magnetic field, which in all dynamos tends to weaken the first and important magnetic field. Hence the best dynamos have been so designed that while the exciting electro-magnets produce a very strong field, the armature shall produce a very weak field.

The result has been arrived at partly by making the armature of a dynamo small compared with the exciting electro-magnets, and partly by giving it a squat form; but, in a motor, we have concluded from certain theoretical and practical considerations that, on the contrary, the strengths of the two magnetic fields produced by the exciting magnets and by the armature should be equal, and since the armature, from its shape, is necessarily rather a weak magnet, whereas the field or exciting magnet, from its shape, is a strong one, we have reversed the usual conditions of

FIG. 5.—Ayrton and Perry's Electro-motor.—Commutator.

things, and made the armature large and the field magnet small, and from this we have been led to make the armature stationary and surrounding the field magnet, instead of, as usual, the field magnet surrounding the armature. This little thing, then (A, Fig. 4), which I hold in my hand, and which you might at first sight mistake for a Siemens armature without the commutator, is in reality not an armature at all. In our motors the current always flows in the same direction through any portion of the wire coiled on this interior bobbin, A, which is, of course, the condition of a field magnet; while in any part of the wire coiled on E E, the stationary portion of the motor, the current is reversed in every revolution, and this is the condition of an armature. Our small field magnet, then, carries the brushes and revolves inside the stationary armature, the coils of which are joined to the stationary commutator, which, unlike ordinary commutators, we make flat (Fig. 5), to save both space and expense; and in this way we have, we believe, obtained, *weight for weight*, a much more powerful motor than can be obtained by using a dynamo, as well as a more efficient motor *for its size*—that is, the ratio of electric power put into mechanical power given out is greater than in the case of a dynamo of the same size used as a motor.

I say intentionally "for its size," because not only does the horse-power of a motor increase far more rapidly than its weight when the same current is flowing through it, but so also does the efficiency. The increase of power is between the fourth and fifth power of the linear dimensions of the motor, while the weight and cost only increase with the cube. For example, one of our motors, such as there are many examples in this hall driving the various tools, weighing under 40lb., will produce effectively half a horse-power, while one twice as long and of twice the diameter, weighing, therefore, 320lb., or eight times as much, will produce from eight to 10 horse-power, that is from 16 to 20 times as much. Very small motors, producing,

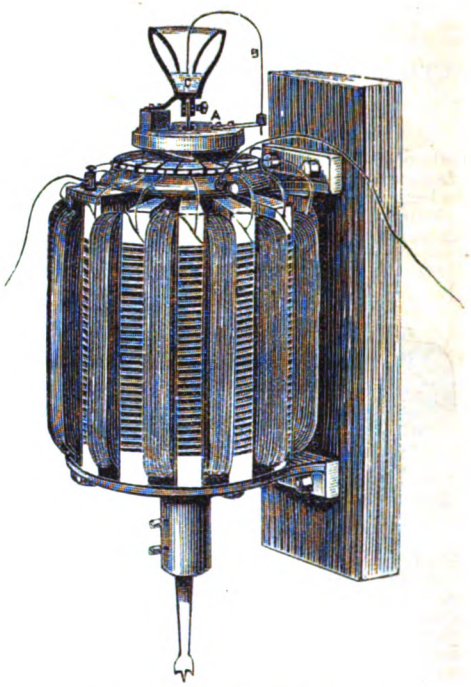

FIG. 6.—Motor, with Drill attached.

say, one-twentieth of a horse-power, can have only quite a small efficiency, are, in fact, not economic converters of power, while motors producing several horse-power, experiment shows, may, when properly constructed, have an efficiency of from 70 to 80 per cent. Why, then, ever use small motors at all if larger ones are so much more efficient? Because the total waste of power when any motor is used to drive machinery does not only occur in the motor itself, but also in the shafting employed to transmit the power to the machine, and in the belting, toothed wheels, or other gearing employed at the machine itself to produce a high speed if it be a fast-speed machine. Consequently, for quick moving, small tools like drills, emery wheels, small circular saws, small electro-motors are of great value, since

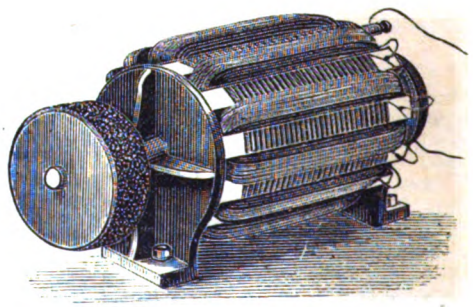

FIG. 7.—Motor, with Emery Wheel attached.

not only does the entire absence of all intermediate gearing, but the enormous convenience of being able to bring machine-driven tools to any part of the work instead of having to bring the work to the tool far more than compensates for the efficiency of small electro-motors being less than that of larger ones. And for large quick-moving machines like fans, centrifugal pumps, screws of small launches, &c., large electro-motors will be invaluable, since they will combine high efficiency with absence of all shafting and the power of shifting the position of the motor and machine at will in the workshops. Hence I believe that for all quick-moving machines, small or large, electro-motors will play an important part in the fitting up of our workshops.

[Portable drills, emery wheels, small circular saws, as well as a fan and a centrifugal pump, were then shown, driven with Ayrton and Perry's electro-motor, sketches of which are given in Figs. 6 to 9.]

But you may have observed in these rough experiments that the motor increased in speed when the work was taken off. If this were unavoidable

Digitized by Google

it would be a serious hindrance to the general adoption of electro-motors for commercial purposes. It would never do for a piece of wood or iron in a lathe to rush round when the chisel was taken off, since not only would there be a great waste of power, but on next applying the chisel it would be probably broken by the wood or iron when rotating with such an excessive velocity. It would never do for the screw of an electric launch to race when the boat pitched; this difficulty is bad enough in the present steamers, where a certain amount of racing has to be tolerated because the steam engine cannot be perfectly governed, but with a simple electric motor it would be much worse.

Not only, then, must we arrange, in the way I have described, that the supply of electric energy is proportioned to the demand, but also that the motors consume this energy in proportion to the work they have to do, in other words, the electro-motor must be governed so as always to run at the same speed whatever work it may be doing. The oldest form of governor for motors is what I have called the "spasmodic governor." I will show you it in action, and then you will see the reason for the name

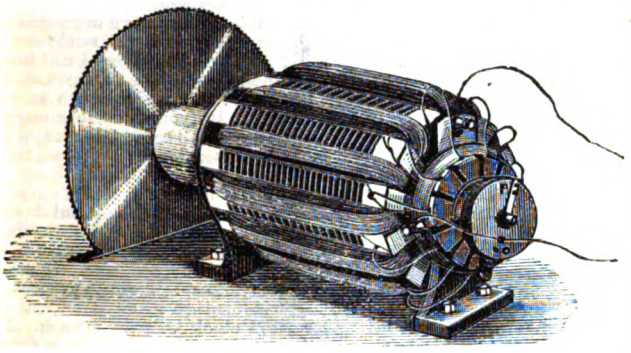

Fig. 8.—Motor, with Circular Saw attached.

(see Fig. 6). The form I am using here is simply a mercury cup revolving with the motor driving this drill. When the mercury revolves, the surface, as you all know, assumes a cup-shaped form, the centre being much lower than the edges. A wire, dipping into the mercury at its centre, carries the electric current into the mercury, whence it passes through the motor; but when the mercury revolves faster than at a certain definite speed, the centre of the mercury becomes so low that the wire ceases to touch it. The current is then temporarily stopped, and the motor slows again until the mercury again rises to the end of the wire.

The objection to this motor is exactly the same as the objection to the ordinary governor supplied with gas-engines—either full power is supplied or no power at all. The result is that the motor slows until a certain moment, when it suddenly receives full power. It then goes off with a rush, continuing to receive full power until it goes so fast that all power is cut off; the speed then rapidly falls, and the same spasmodic action is repeated. Now what we want is, not this alternation of no power and full power, but a supply of power proportionate to the work the motor is doing at any particular moment. To attain this object Professor Perry and I have designed our "periodic governor" for electro-motors, a rough model of which you see in operation here.

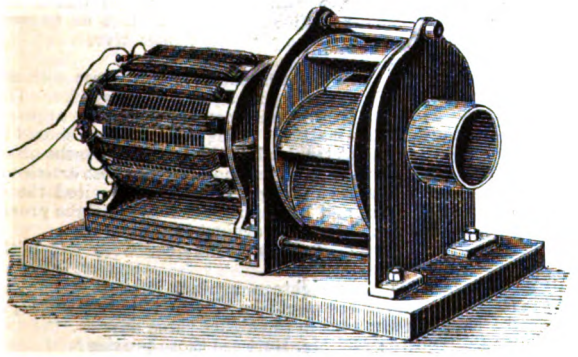

Fig. 9.—Motor, with Fan attached.

If the motors are in series, we arrange that the periodic governor shunts the current periodically instead of introducing resistance.

In some of our motors with flat commutators the periodic governor is constructed as part of the commutator itself, to avoid the necessity of employing any separate apparatus.

With our periodic governor the power is never cut off entirely for any length of time; nor, on the other hand, is full power ever put on for any length of time; but in every revolution power is supplied during a portion of the revolution, the proportion of time in every revolution during which much power is supplied to the time during which less is supplied depending on the amount of work the motor is doing. Our periodic governor, then, differs from the spasmodic governor in the same way that a good loaded governor differs from the governor of a gas-engine.

Having perfected this governor, we then proceeded to abandon it for something better. Why does an ungoverned electro-motor run away when the load is taken off? Because it is using up more of the electric energy than it ought to. Both the spasmodic and our periodic governor operate by diminishing the supply; but there is another way of preventing its running away, and that is by using a brake of some kind to keep the load constant. When the useful work being done is small the brake-power would be large, and when the useful work is large the brake-power would be small, the sum of the two being kept constant. Such a system would obviously be practicable, but not economical, if the brake attached to the motor were to use up the surplus power in producing heat; but supposing the brake stored up the power in some form that could be easily utilised in driving the motor afterwards, then the system of braking would be necessarily be uneconomical, and if the brake was of such a kind that it acted very powerfully when the speed of the motor increased even a little above the normal speed it would be very effective.

Now, such an arrangement we have effected by combining a dynamo with the motor in a variety of different ways. The motor, as is usual, converts electric energy into mechanical energy, while the dynamo reconverts some of this mechanical energy into electric energy, which is added to that supplied by the mains; and by arranging the resistance in the dynamo circuit so that the desired speed of the motor corresponds with the critical speed of the dynamo, the brake power exerted by the dynamo becomes extremely large if the speed of the motor even slightly exceeds the prearranged speed. Here I have an experiment which illustrates our principle in its simplest form. One of our motors is geared with a dynamo, so that both run together, at a speed which is the critical speed for the resistance in the dynamo circuit. You see, on putting a load on the motor, I scarcely at all diminish its speed, and on withdrawing the load the speed of the motor hardly increases. But we can go further than this, for we can combine the motor and the dynamo in one machine. Consider an ordinary series dynamo—if you turn it with the brushes it produces a current, if you supply it with electricity it will run backwards against the brushes. Suppose, now, we wound it with two distinct circuits in *opposite* directions. On sending a current through the core it would turn as a motor one way, on sending it through the other it would turn as a motor the other way. What would happen if you sent a current through both at the same time, and if one of the circuits were less powerful than the other? Why, the current passing through one would make the machine turn as a motor, producing a back electromotive force, so that the current, as is usual in motors, would be checked, while the current flowing through the other circuit would be helped on, since for that circuit the machine is acting as a dynamo. Well, that is the principle of our machine. We wind it with two circuits in *opposite* directions, such that the main current passing through one of them magnetises the armature and field magnets, and so produces the motion, while the main current passing through the other demagnetises the armature and field magnets, tends, therefore, to stop the motion, and is in consequence helped on itself.

I will conclude this lecture by showing you one of the motors thus governed in action, and will reserve until my next lecture, on March 15th, the consideration of the peculiar effect of the lead of the brushes in such motors, and when I shall also consider in detail the construction of the permanent way for electric railways, and of the mains where enormous potentials are employed. I shall also say something about the use of stored electricity for tramcars and tricycles, and when, if the room allows, I will show you our electrically-driven and lighted tricycle running.

THE MEDITERRANEAN EXTENSION TELEGRAPH COMPANY (LIMITED).

The fifty-first ordinary general meeting of the shareholders of this Company was held at the City Terminus Hotel on the 2nd inst., under the presidency of Sir James Carmichael.

After the adoption of the report and the declaration of the dividends on the ordinary and preference stocks,

Mr. Burt said I desire to say a word with respect to what took place at the last meeting. Unfortunately I was ill, and not able to be present, but I observed from a report of what took place at the meeting that there was some misunderstanding with regard to a letter I had written to the secretary respecting the purchase of the Company's undertaking. I am here as an ordinary shareholder of some years' standing—a very small shareholder, I admit—but it appears to me that the position is such that the ordinary shareholders ought to carefully consider the matter. On the last occasion some exception was taken to a paragraph in my letter with respect to the reserve fund, and it was remarked (and I think perhaps truly) that it was no business of the Eastern Telegraph Company what the shareholders should do with their reserve fund. I desire to discharge myself of any impertinence as to that suggestion in this way. I was asked to divide the purchase-money of £40,000 which was offered between the preferred and the deferred shareholders. I said in my letter that I thought it was not my business to do that at all—that it was more for the shareholders to do it, but I was told by an authority almost that I must do so, and I accordingly did it, and it appeared to me, although it was only a suggestion, that something should be said to call the attention of the shareholders to the fact that there was a reserve fund to be divided among them in addition to the purchase money. I see by the report of the meeting that, although the directors had solicited proxies from the shareholders, asking their opinion as to whether the offer should be accepted or not—although there were eighty-three proxies in favour of the purchase and eighteen against, nevertheless the directors did not act on them, but I suppose voted against the proposal, and, consequently, it was rejected. That, however, is an affair of the directors and the shareholders who were then present. Still, I think the shareholders should understand their position. Now, the position is this: The Government guarantee has now ceased; the shareholders can now only look to the revenue of the Company for a dividend in future. For several years past—I have not the accounts by me—but I think I am right in saying that never has there been a net revenue from the earnings of the Company exceeding £1,500. That, sir, is not nearly enough to pay a dividend on the preference shares. Consequently, unless some extraordinary event arises by which the profits of the Company are to be doubled beyond what they

Digitized by Google

have been for many years past, it is perfectly clear that the ordinary shareholders can never see a dividend again; and it appears to me that that point was hardly brought out for the consideration of the last meeting. I venture to call attention to it now in order that the matter should be considered. I have no desire to press a sale in any particular way, but I wish to call the attention of the shareholders, and particularly of the ordinary shareholders, to the point that, as far as I can judge, they will never receive a dividend. It appears that the present payment of 1½ per cent., which is only half the amount hitherto paid, is paid out of the Government guarantee of £3,000. The report says: "The claim due from the Treasury for the five months ended the 2nd December, when the Government guarantee expired, is £3,000. This sum will suffice to pay the usual dividend on the preference stock, and also a dividend of 1½ per cent. on the ordinary stock." Now, sir, I invite the attention of the preference shareholders also to their position, because my impression is that they are under a misapprehension as to what their rights are. It is scarcely to be expected that with our large amount of ordinary capital, which I think is £120,000, the shareholders will permit all the profits of the company, being the miserable sum of £1,500 a-year at the outside, to be absorbed by the preference shareholders in future. I should think not. I, for one, should object to it. But if some arrangement were made for the sale of the undertaking, either to the Eastern or to some other company, or in some way to put the affairs of the Company on a reasonable basis, by which there would be something given to the ordinary shareholders and a fair proportion to the preferred, I think then that we might consider that the business of the Company might be carried on as hitherto. But if you look at the detailed statement on the last page you will see how the expenses stand. You see directors' fees and officers' salaries are £441, rent of offices, &c., £57. I do not complain of that being excessive for the Company at all. Then, at Malta, the salary of the superintendent, wages, &c., come to £496. At Corfu the salary of the manager and wages are £222, and the total amount altogether for expenses is £1,663 for the half year. And on the other side you see that the total receipts for messages were £2,307. The report says that the receipts for the last half year were rather less than for the corresponding half year of 1881. But, sir, I cannot find that there ever has been any considerable increase over £2,300 for a half year. If you can tell the shareholders that there is a probability of a large increase, then there is something to wait for, perhaps. But, in the meantime, the £120,000 of ordinary capital which has been spent on the cables is to produce nothing, and we are to go on year after year—I do not know what waiting for—till all the cables are dead, because they are twenty years old, I believe. Mr. Campbell was good enough on a former occasion to give me the dates of the cables when laid, and my impression is that one of them is twenty years old. We can hardly expect that there will be no further repairs to those lines. During the last two years there has been £2,000 spent on the repairs of the Corfu cable, and we know by other companies that repairs are very frequently required, and I suppose that in our case the expense will have to come out of revenue, or, at all events, out of the reserve fund. It seems to me that we are wasting away, and that, unless something is done to realise very promptly, there will be nothing in three or four years left for the preferred or the ordinary shareholders. I think, therefore, that these matters should be taken into very serious consideration.

Mr. HURST: As an ordinary shareholder of the Company I should like to propose a resolution that will have the effect of re-opening negotiations with the Eastern Telegraph Company. The resolution I would propose is—"That a committee of shareholders (say five) be appointed to consider with the directors the expediency of negotiating for the sale of the Company's property, and report to a special meeting on the subject as early as practicable." I do not see that we can possibly gain anything by going on. I do not hold preference shares but I do the ordinary shares, and I do not see any chance of getting a dividend. If we divided our reserve fund it would give us something like 50s. a share, which is better than nothing.

Mr. HERBERT: I second the proposition.

The CHAIRMAN: I would just answer Mr. Burt. There is only one allusion in his remarks that I need answer, because, as far as the negotiations with the Eastern Telegraph Company are concerned, they were fully discussed at the last meeting. The whole subject was then placed before the shareholders in the most open form possible. Your letter was sent to them *in extenso*, without a word altered, and their opinion could be formed of it, and the directors most carefully abstained from influencing the shareholders in any way whatever. I and all my colleagues stated one after the other that we did not wish to affect their views, till we were pressed as to what way we should vote, and then I stated that as a shareholder I would sooner take my chance of holding the property instead of selling it at that price. That I said as a shareholder. The whole thing was discussed fully, but we can go over it again. It was very fully discussed, and the offer was rejected unanimously. I did not think we were called on to use proxies when that meeting was so decidedly against the adoption of the proposal But out of those proxies we had a great many sent to use as we thought best, which we declined to do. A great many were also in favour of the purchase, I am bound to say. Another reason why the Board was very anxious not to use the proxies was that a great number of them (the bulk of them in favour of the purchase) had not been signed properly.

The SOLICITOR (Mr. Campbell): The articles require a witness in this case.

Mr. BURT: The proxies were sent out by the Board in proper form?

The CHAIRMAN: The form was perfectly correct, but many of them were sent back irregularly signed. I merely mention that, because we were glad not to use them.

Mr. BECK: Had the offer been made in money, it would have been very wise to accept it, but when such a small amount had to be paid to the ordinary shareholders it seemed absurd to accept it. If money had been offered as the price it would have been different.

The CHAIRMAN: It was the unanimous decision of the meeting, and the directors did not influence it in any way. If the present meeting wish another offer to be made to the Eastern Company we shall be glad to do so.

A SHAREHOLDER: I beg to move that if it be offered in cash it be accepted.

Mr. FORD: A proposition is before the meeting.

Mr. HURST: My proposal would not bind the meeting, but it opens the question with the Eastern Company, and they might propose something more.

The CHAIRMAN: I think Mr. Burt is the person who had charge of the negotiations, and he will give you his opinion whether they will give you any more. Mr. Burt distinctly told me that they would give no more—in fact, that it was above the value.

Mr. FORD: I should like to know whether the chairman can controvert or explain away the financial position of the company in the future, as prognosticated by Mr. Burt. Is there any prospect whatever of this company's operations realising a dividend for the ordinary shareholders, or indeed of paying the dividend upon the preference shares? I venture to say not. Any man who understands the working of a telegraph property will understand that, and something must be done.

The CHAIRMAN: I quite admit that something must be done.

Mr. FORD: If not the reserve fund will be wasted away. This proposal should be put to the shareholders.

Mr. ATTRELL: I have been connected with companies in the City of London all my life time. I have seen a good deal of committees, and in nine cases out of ten it has been a failure where committees have been appointed. I do hope that we shall have no committee appointed here to assist the directors in a little affair like this. If we have not confidence in those gentlemen to look after our affairs the sooner you send them about their business the better. I say a little concern like this—I call it a little concern—to ask for a committee to go and assist them in negotiating with a large concern like the Eastern Company, they would laugh at you. I say that, if you wish negotiations to go on, let your directors carry them on, but do not let the Eastern Company see that there is dissension among yourselves. Directly they see there is dissension among you, they will say, "Now is our time."

Mr. FORD: Do you suppose they do not read the reports?

Mr. ATTRELL: Perhaps they do; but it is not always put down, and therefore, if an amendment is necessary—however, I shall vote against the resolution. But there will be no committee, I hope, and I trust that you will see with me that it would be impolitic to appoint one. If you have anything to offer to the Eastern Company, do so. I would propose this—that if they will give us a five per cent. debenture we shall accept it, and not 4 per cent., and that all under £100 stock be paid in cash. I think that would meet the little shareholders, and would save them a good deal of bookkeeping and a great deal of trouble, and they can carry on the business of this little affair without much trouble. I would propose that we accept 5 per cent debentures—£50,000, if you like to name a sum total, in 5 per cent. debentures—and that all sums under £100 be paid in cash. I do not know if that suggestion will meet your wishes, Mr. Chairman.

Mr. HURST: I do not wish it inferred that there is any dissension, but the directors have said that they do not wish to take the responsibility, and they did not like to give their advice. At the last meeting we had to press them for their opinion. That being so, it is no dissension to say that we should like to sell our property, with your concurrence, and we should like to negotiate with you to see what terms the Eastern Company would give us. As to what the last speaker said about the terms we shall find that out in the negotiations. But surely as men of business it must be advisable to move now. If a cable break we should have so much less reserve fund to divide. I would ask you to put the resolution Mr. Chairman.

The SOLICITOR: I would say to Mr. Burt, is there not a little inconvenience in passing a motion like this? A larger number of shareholders were at the last meeting who were of opinion that the negotiations should end. If there is to be any renewal should they not be present to say whether they should be renewed?

Mr. FORD: They have been summoned to this meeting. This is a matter I should say for the decision of the meeting.

The SOLICITOR: Let me finish what I was saying. Mr. Burt well knows that a resolution like that is perfectly inoperative as a legal resolution, but if a majority of the shareholders present were of opinion that the negotiations should be begun again by the directors, I have no doubt that the directors would follow the wish of the shareholders. But as to passing a cut-and-dried resolution like this, it is perfectly inoperative.

Mr. FORD: It is perfectly legal.

Mr. BURT: I venture to think the shareholders will agree with me that it is a matter completely for the meeting to agree on if they like. There is nothing binding the Company to a specific course, except the appointment of a committee to consider the matter. Being on my legs I should like to say this: I have been somewhat troubled in the last few months about the question of witnesses to proxies, but I find nothing in these articles about witnesses to proxies. I confess I thought that having invited the shareholders to do what they liked, and having received eighty-three proxies for the acceptance of the offer, and eighteen against it ——

The CHAIRMAN (interposing): A large number were left with the directors to use as they pleased.

Mr. BURT: There were only eighteen against it, and I should have thought the duty of the directors would have been to act on the expressed wish of the shareholders who sent in the eighty-three proxies.

The Hon. A. PONSONBY: Did Mr. Burt see those proxies?

Mr. BURT: No, I did not.

The Hon. A. PONSONBY: I should have liked you to see them.

The SOLICITOR: There were several proxies (I do not quite remember what the point was) that appeared on the face of them to be quite illegal.

Mr. BURT: I dare say that applied to the eighteen as well as to the eighty-three.

The SOLICITOR: I do not know. We will have the proxies looked at and tell you the point, but a great many were not signed at all.

Mr. BURT: How can you call that a proxy? I am not, however, in controversy with Mr. Campbell. I take the report of the meeting at which the chairman said that eighty-three shareholders sent in proxies in favour of the offer. It is also said that there were eighteen against it, and my complaint is that the eighty-three shareholders' views were not attended to at all, and that the eighteen shareholders' were. I desire to point this out to the shareholders also, and to the directors of the Company also.

Mr. ATTRELL: What is the amount of capital the two sections represent?

Mr. BURT: I will say no more. I leave it to the meeting. I think on the last occasion the directors refused to express any opinion as to the proposition, but I am surprised that the directors did not give any advice.

Digitized by Google

As they did not, it must be a question for the shareholders to settle outside. The directors are a small body, holding 270 shares. Two are directors of a company competing with the Eastern Company. That may be a good reason why they should not have voted against the offer or for it.

Mr. C. H. ROBINSON: You are wrong.

Mr. BURT: I understood that the chairman and Mr. Ponsonby were directors of the Submarine Company.

The CHAIRMAN: So we are.

Mr. BURT: That company is in competition for a large amount of business with the Eastern Company, and that is a reason why the directors should have hesitated.

The Hon. A. PONSONBY: I hold a largish number of shares in the Company—170; and I do think your offer a good one. I think, Mr. Ford, you are a director of the Eastern Company.

Mr. FORD: No.

The Hon. A. PONSONBY: No? Of the Globe? Well, it is the same thing.

Mr. BURT dissented.

The Hon. A. PONSONBY: I do not think the offer was good enough. I think we may have the negotiations again, and I should like to get a better offer.

A SHAREHOLDER: Can you do so?

The Hon. A. PONSONBY: Ah!

Mr. ROBINSON: This meeting, it appears, has taken a very wrong view of the positon of the Company. The great difficulty the Board have had has been in ascertaining what the shareholders would like to accept. It was no use asking for £3 a share when the market value was only £2. Therefore, as long as you entertain views of that kind, it is useless trying to approach the Eastern Company. A year and a half ago you were offered, I may almost say, £2 10s. per share. Then you repudiated the offer with contempt. You said: "No, unless we get £3 we will not take it." What were the directors to do? The Eastern Company said: "We will not give you £3." It is for you to say or express an opinion what you think your property is worth, because without that the Board have no power. They may say to the Eastern Company, "What will you give?" and the Eastern Company, "What will your shareholders take, and what do you recommend?" You say £2 10s., and they say £3. Another time they say they will give you £1 10s., and you say it was absurd. So it was. Your property is worth more; and there is no doubt, if you keep it long enough, you will realise more. At the same time, you must express some opinion to the Board as to what you think the property is worth. Mr Ford is very well versed in telegraph property. He is a shareholder and, I believe, a director of the West India and Panama Company, which, with all its advantages, is worse off than the Mediterranean Extension, for they pay no dividend at all. They have an immense capital, and pay nothing. Mr. Ford represents the whole of the Board because he was always there, and did everything. If he is so powerful as he expresses himself to be at general meetings——

Mr. FORD (interposing): This is most irregular.

Mr. ROBINSON: I am sure you have only to chalk up to yourselves something that you think the value of your property, and then you will give us some data to go upon, and we will try and carry out your wishes. If we cannot get what you wish, we will see what we can get.

Mr. HURST: I should have been prepared to take £3. I should be very pleased if any one would offer me £2 10s. now. I should be very glad to enter into some negotiations.

Mr. BURT: What is the price in the market?

Mr. HURST: 1½ to 2. I should be very pleased to take £2 10s. I hold 450 shares, and I should be very pleased to sell them. We know in buying and selling we are always willing to take less after a time, and I think this is an occasion for doing so.

Mr. FORD: Mr. Robinson has addressed me personally, and has asked me why I did not get them an offer. If the shareholders place me in a position to endeavour to do something to open negotiations with the Eastern Company, I have not the slightest hesitation in accepting the responsibility; but until I am invited by my fellow shareholders to take that step, I shall not take on myself the invidious position of negotiating on their behalf. That is the only answer I can make to what I consider a very unnecessary and personal reference to myself.

Mr. HURST: Will the chairman put the resolution to the meeting?

A SHAREHOLDER: Is Mr. Ford's resolution an amendment to this?

Mr. FORD: I proposed nothing.

The SOLICITOR: An amendment can be moved if it is wished.

Mr. FORD: The resolution can be negatived; it is a distinct proposition before us.

Mr. ADAMS (to Mr. Ford): Would it not be well for you as you are so anxious in the matter ——

Mr. FORD: I have no anxiety on the subject.

Mr. BECK: The same idea struck me. There is a great anxiety in this room on the part of some one representing the Eastern Company—not this Company—and you had better be careful what you are doing.

Mr. HURST: I have no interest in the Eastern Company. I am a shareholder, but to a less extent than in this Company, and a very valuable property I have there.

The CHAIRMAN: I think you will have placed the Board in rather a false position if this is carried, because at the last meeting you decided something totally different, and I do not know anything to-day that has altered the position.

Mr. BURT: Will you read the proposition?

The CHAIRMAN: "That a committee of five shareholders be appointed to consider with the Directors the expediency of negotiating for the sale of the Company's property, and to report to a special meeeting on the subject as early as possible."

Mr. BURT: It says nothing about the Eastern Company?

The CHAIRMAN: It alludes to the Eastern Company, as no one can negotiate but them.

Mr. FORD: That answers Mr. Adams, who suggested that you should negotiate with some other company.

The CHAIRMAN: There is no other company in the Mediterranean.

Mr. ADAMS: I was stopped when I was going to say a word. By going to the Eastern Company, and continuing begging, you will be doing mischief. I merely want to put it to the shareholders whether, if they were going to sell a horse or any other animal—an ass, say—whether they would go to the buyer on their knees and ask more for it than he had offered already. The property must be sold, or not sold. It is a bad concern, but it is very often that you can get a good price for a bad concern, if you do not keep pressing the matter on the buying company. You had an offer by the Eastern Company, and the shareholders refused to take it. If the Eastern Company are willing to give that now, the directors cannot prevent the shareholders from accepting it if they pleased. But I would not have a committee going on their knees, asking the Eastern Company what they are going to give. Let the matter be placed in the hands of the directors of the Company who wish to go to them again. I would keep out, and try some one else.

Mr. FORD: If you can find them.

Mr. ADAMS: It must be left to the shareholders to decide what they wish. If they wish a committee let them have it. If they go to the Eastern Company again, asking for more, they will probably get less. That is my experience of business. I think there are many other companies in the market that might like to take up your cable as a nucleus.

Mr. FORD: Will you mention a company?

Mr. ADAMS: Let me finish, and then I shall be glad to hear your ideas. I will not weary you much longer. If the directors cannot get a better price for it, or if they cannot get a better offer for it, as one of the directors—Mr. Robinson—has said, let the shareholders say what price they will take, and then let us try and see if we can get it.

A SHAREHOLDER: May I ask if Mr. Ponsonby's mind has changed since the last meeting?

The Hon. A. PONSONBY: The offer was one which, as a shareholder, I should not have liked to accept. I would not give my opinion as a director as I said at the time, because I ought not to bias any one's mind. I am not a preference shareholder but an open holder, and I said I did not think the offer was one that I should like to take, and that I would prefer taking my chance, and trust to the chapter of accidents. My views are the same now. I daresay the Eastern Company felt they could not give more, but I did not think it sufficient, and, therefore, as I told you, speaking as a shareholder, I should vote against anything in the shape of accepting the offer that was then made. As a director, I gave no opinion about it.

The CHAIRMAN: I think it is only fair to tell you that we do not agree to this proposition. As chairman of this Company, and as a member of your Board, I shall be most happy to carry out any instructions, but I could not put myself in a false position, and go and ask the Eastern Company, backed up by several shareholders, to buy us up.

Mr. FORD: That is not the proposition. It is not proposed that you should go to them. There is no proposition of the kind.

The CHAIRMAN: It is a proposition to go to someone, "That a committee of five shareholders be appointed to consider with the directors the expediency of negotiating for the sale of the Company's property, and to report to a special meeting on the subject as early as possible."

Mr. FORD: That meets the views of Mr. Adams, but does not bind you in the least. We wish you to go to the best buyer.

The CHAIRMAN: That is moved and seconded. Will the shareholders signify their approval of it in the usual manner? To the contrary. Then it is rejected. That concludes the business of the day.

Mr. FORD: I have a poll to ask for. Will you let me see a copy of the Articles of Association, to see in what form I can put it?

The SOLICITOR: Any five shareholders present at any meeting may demand a poll. [Read clause in Articles of Association on the subject.]

Mr. FORD: Then I hope we shall have a poll at once.

A SHAREHOLDER: I think a poll is entirely unnecessary.

Mr. FORD: I will sign the demand if you give me a piece of paper.

A SHAREHOLDER: Are there five to demand a poll?

Mr. FORD: If four other shareholders besides myself will sign the demand I will write out the request for a poll.

Mr. BURT: Might not this be avoided if you have this matter brought before another meeting specially called for the purpose? I feel that you are in a most awkward position, and so am I. My belief is that the shareholders do not and did not understand their position. If you will have a meeting convened specially for the purpose, you might have a definite resolution on the matter.

The CHAIRMAN: We have done that.

Mr. BURT: No; you had eighty-three shareholders for it and eighteen against it, and then you accepted the eighteen, and refused the eighty-three.

The CHAIRMAN: You leave out those proxies which were illegal. The bulk of the shareholders did not sign.

Mr. FORD: I saw by the report of the last meeting that eighty-three shareholders sent in proxies in favour of the offer of the Eastern Company. There were eighteen against it, and twenty-one sent in proxies requesting the directors to vote as they thought best; so you see eighteen and twenty-one make thirty-nine against eighty-three for the offer. When will the poll close?

The SOLICITOR: It cannot be closed in less than four hours from now. That will be six o'clock.

Mr. ADAMS: I do not think it is a legal way of doing it without notice.

Mr. FORD: Your objection comes too late, Mr. Adams.

The SOLICITOR: The poll is now open, and it will close at six.

Mr. BURT: When will the result of the poll be declared? I suppose you will adjourn the meeting until Monday or Tuesday?

The SOLICITOR: I do not know whether the directors will be here at the close of the poll.

Mr. BURT: I suggest that you adjourn the meeting until Monday at twelve o'clock.

The CHAIRMAN: I think we had better take the poll now, or you will not get people back.

The SOLICITOR: The poll is open now, and it will close at six o'clock.

Mr. BURT: Supposing the resolution is carried, you must carry it out by appointing a committee.

Mr. FORD: A suggestion might be made, which might possibly meet the views of the Board and the shareholders who are of opinion with you that it is inexpedient to appoint a committee. What I suggest is that some expression of opinion should be given on the part of the Board—that if any gentlemen here present as shareholders think proper to bring any proposition to the consideration of the Board, either from the Eastern Company or some other company, that the Board will submit it to the shareholders at a special meeting to be called for that purpose. There

Digitized by Google

you have the question raised independently, and then probably the challenge which has been given to me by Mr. Robinson will be taken up.

Mr. ADAMS: That is a perfectly fair proposition.

The Hon. A. PONSONBY: You get a larger offer.

Mr. FORD: Then I think we may save the shareholders further trouble if the directors, through the chairman, say they agree to this suggestion.

The CHAIRMAN: I have never kept back any offer, and I never would.

Mr. FORD: Do I thoroughly understand you that if any number of shareholders here present think proper to approach the Eastern Company, or any other company, and obtain an offer from the Eastern Company, or any other company, that you will call a special meeting to consider that proposal?

The CHAIRMAN: Certainly.

Mr. ROBINSON: Of course.

Mr. FORD: Then I do not think it is worth while now proceeding with the poll.

Mr. BURT: But if a meeting is called, and the directors will not give any advice about it ——

Mr. FORD: Well, after what has taken place the Board must do something.

Mr. BURT: I think that Mr. Adams has some one in his mind.

Mr. ADAMS: I have.

The Hon. A. PONSONBY: We only want the best offer we can get for our shareholders.

Mr. ROBINSON: Mr. Ford seems to entertain a wrong opinion—that the directors on this Board are adverse to any meeting.

Mr. FORD: I have not expressed any opinion on the subject.

Mr. ROBINSON: The Board have always been desirous of an amalgamation, and no doubt if Mr. Ford, if the Eastern Company, with which I believe he is connected, will bring forward some offer that is tangible, the Board will only be too happy to entertain it, and therefore, with such a view, I think, having a committee would be really frustrating the object Mr. Ford has in view.

Mr. FORD: Are you not mistaken in what you say?

Mr. BURT: It took me more than three months to get the last offer put before the shareholders.

Mr. FORD: I am entirely in the hands of the meeting. A poll has been demanded, and cannot be withdrawn, if Mr. Burt objects.

Mr. BURT: I do not want the affair to sleep and die, as it will if we go on as now.

The CHAIRMAN: Are we to go to a poll or not?

Mr. FORD: Very well, then; let it continue.

Mr. ADAMS: Have you not settled, Mr. Ford?

Mr. FORD: I cannot. Will the gentlemen now, who are favourable to the resolution, sign the demand for a poll?

The SOLICITOR: Two o'clock on Monday is the time appointed to declare the result of the poll.

Mr. FORD: It closes at six to-day.

The proceedings then terminated.

The adjourned meeting was accordingly held last Monday at the City Terminus Hotel, under the presidency of Sir James Carmichael.

The SOLICITOR read the result of the polling as follows:—For the resolution seven shareholders, in person, representing 708 shares and 105 votes; against the resolution thirteen shareholders, in person, representing 534 shares and 77 votes. The proxies in the hands of the directors were nine, representing 1,160 shares and 190 votes. This made 267 votes against the resolution, and 105 votes for it.

The CHAIRMAN having formally declared the resolution lost,

Mr. BURT inquired if the directors claimed to act on the votes given them by proxy?

The CHAIRMAN: Certainly.

Mr. BURT stated that they were not referred to at the last meeting. Had it been intimated that the directors held proxies, he did not think that the demand for a poll would have been pressed. He was sorry that the shareholders were not given this information, as he believed it would have saved trouble and some expense. It appeared, however, from the figures read by Mr. Campbell that the votes in favour of the resolution given in person—that was, by those who had a knowledge of the facts—considerably exceeded those of the shareholders who voted against it, who did not possess a knowledge of the facts.

The SOLICITOR admitted that there was a small excess.

Mr. FORD stated that from what Mr. Burt had said the resolution had practically been carried. It had been carried by the votes of the shareholders present, but it had been defeated by the votes of proxies held by the directors. It had not been stated at the time by the directors that proxies were held by them, or that they were intended to be used by them.

The SOLICITOR: That shows what an irregular proceeding it was to allow the resolution to be put at all, seeing that the majority of the shareholders, being absent, knew nothing about it.

Mr. BURT: That irregularity, of course, must rest on the solicitor of the company.

The SOLICITOR: The solicitor of the company pointed out the irregularity, but deferred to the minority of the shareholders.

The CHAIRMAN stated that he must himself accept the responsibility, for he had overruled Mr. Campbell's advice, wishing to give the shareholders an opportunity of expressing their opinion.

Mr. BURT, after remarking that no harm had been done, moved a vote of thanks to the chairman.

Mr. THOMAS ADAMS seconded the motion, which was carried unanimously.

The CHAIRMAN briefly replied, and the proceedings then terminated.

ELECTRIC LIGHTING IN MELBOURNE. The Melbourne City Council, at a meeting held on January 15, resolved to ask the city members to introduce a Bill for the electric lighting of the city.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of the Cuba Submarine Telegraph Company during the month of February was 4,400, estimated to produce £3,900, against 3,349 messages, producing £3,271 in the corresponding month of last year. The traffic receipts for the month of November, estimated at £1,800, realised £1,842.

Digitized by Google

SLIP

SPAIN.—The cable between Falmouth and Bilbao is interrupted.

WEST INDIES.—Telegraphic communication with all the West India Islands and with British Guiana is now restored.

ELECTRIC LIGHTING FOR THEATRES.—It is stated that the Court Theatre, in Dresden, is to be lighted by the Edison system.

THE EDISON SYSTEM IN BOSTON (AMERICA).—One hundred and fifty Edison lamps are used in the new building of the Boston *Advertiser*.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended the 9th inst. amounded to £4,577.

ELECTRIC LIGHTING IN SOUTH AFRICA.—Recent news from South Africa says that the Town Council of East London has agreed to adopt the electric light.

BATTERIES AT THE POST OFFICE.—There are 87,221 Daniell, 56,420 Leclanché, and 21,846 bichromate cells at present in use in the British Post Office telegraph system.

ELECTRIC LIGHTING FOR OTTAWA (CANADA).—The Corporation of Ottawa is negotiating with a New York company with regard to lighting the city by electricity.—*Colonies and India.*

CIVIL SERVICE ESTIMATES.—According to the estimates for the year ending 31st March, 1884, £1,550,073 will be required for Post Office Telegraphs. This is an increase of £114,157 on last year.

DIVIDEND.—The directors of the Brazilian Submarine Telegraph Company have declared an interim dividend of 3s. per share, or 6 per cent. per annum, free of income-tax, for the quarter ended December 31st last.

ELECTRIC LIGHTING IN SYDNEY.—It is stated that the General Post Office, Sydney, is to be lighted by electricity. The sorting room of the postal department and the operating room of the telegraphic department are to be lighted on Edison's system.

ELECTRIC LIGHT AT NEWLAND HALL.—Newland Hall, near Normanton, the residence of William Locke, Esq., has been lighted throughout by means of Swan lamps and a Siemens dynamo. Messrs. Tasker, Sons, and Co., of Sheffield, are the engineers.

EDISON SYSTEM IN MELBOURNE.—News from Victoria says that the Chamber of the Legislative Council was illuminated on the evening of January 22 with the Edison electric light, in order that visitors from South Australia and Queensland might be able to compare it with gas.

ELECTRIC LIGHTING ON SHIPS.—The "Doric," a new steamer recently built by Messrs. Harland and Wolff, of Belfast, for the White Star Line of Liverpool, is to be lighted by incandescent lamps. She is 440ft. long, 44ft. broad, 32ft. deep, and has a gross tonnage of 5,000 tons.

THE ELECTRIC CARBON COMPANY.—On the 10th inst. a petition for the compulsory winding up of this company, which was already in voluntary liquidation, was heard before Vice-Chancellor Bacon. The petitioner described himself as a judgment creditor in respect of services rendered by him as solicitor. The petition was dismissed.

THE ROYAL SOCIETY.—On Thursday a paper was to be read before this society by Staff-Commander Creak, having for its title, "On the Changes which take place in the Deviations of the Standard Compass in the Iron Armour-plated, Iron, and Composite-built Ships of the Royal Navy, on a considerable change of Magnetic Latitude."

EDISON'S 100-CANDLE LAMP.—In our Notes last week, describing an exhibition of Edison's 100-candle lamp at Glasgow, its dimensions were accidentally enlarged to mammoth proportions. Those of our readers acquainted with incandescent lamps will readily recognise that the figures given should be reduced to inches instead of feet.

COMMUNICATION WITH THE WEST COAST OF AMERICA.—The West Coast of America Telegraph Company announce that telegraphic communication with Valparaiso, Mollendo, Arica, Iquique, Antofagasta, Santiago de Chili, Buenos Ayres, and all telegraph stations in Peru, Chili, and the Argentine Republic, is now re-established *viâ* Galveston.

ELECTRIC LIGHTING AND THE TRANSMISSION OF POWER.—Mr. A. Reckenzaun, C.E., of the Electrical Power Storage Company, is to lecture on this subject at the Working Men's College, 45, Great Ormond-street, W.C., this evening (Saturday), at 8:30. Sir Daniel Cooper has promised to preside. Admission is free, by means of tickets to be obtained of the secretary.

THE TELEPHONE AT WALSALL.—At a meeting of the Walsall Chamber of Commerce last week it was resolved, on the request of the Telephone Company, to petition the Postmaster-General in favour of making West Bromwich a licensed centre, as communication between Birmingham, Walsall, Wolverhampton, Tipton, Dudley, &c., would thus be made much cheaper.

TELEPHONES AND TELEGRAMS.—Mr. Monk, M.P., as President of the Associated Chambers of Commerce, has forwarded memorials to the Postmaster-General urging a reduction in the charges for the use of telephones. Furthermore, the Government is requested to enter into negotiations with foreign countries for the purpose of cheapening and facilitating telegraphic communication.

THE FISHERIES EXHIBITION.—The Executive Committee of the International Fisheries Exhibition have decided, we hear, to light their galleries by electricity, and they have already made arrangements for the illumination of fully two-thirds of the area. Messrs. Davey Paxman and Co. have undertaken to supply the necessary motive power, which has been estimated at little less than 700 h.-p.

ELECTRIC LIGHTING.—Mr. Andrew Jamieson, Principal of the College of Science, Bath-street, Glasgow, gave a free lecture on this subject under the auspices of the Mining Institute of Scotland, on the 9th inst., at Hamilton. The principles of electric lighting were explained, and a number of lamps and machines shown and described, amongst them being the Brush, Gülcher, Crookes, Edison, &c.

TELEGRAPH BOYS.—On Thursday evening last the annual winter gathering of telegraph boy messengers employed in the East Central District took place at the Lecture Hall of the Weigh House Chapel, Fish-street-hill, E.C. Three hundred boys were supplied with a substantial tea. Later on they were addressed by various gentlemen, and congratulated on the improvement they had made during the past year.

THE ELECTRIC LIGHT IN SWITZERLAND.—A *Daily News* correspondent says that a scheme is proposed for lighting the whole of the Canton of Vaud by electricity. The motive

Digitized by Google

force would be derived from turbines of five thousand horse-power at Vallorbes, and, the water supply being constant and abundant, it is believed that gas, which is very costly in Switzerland, may be entirely dispensed with throughout the district.

Electric Lighting in Brighton.—The Hammond Electric Light Company have now something like 10 miles of line in Brighton, supplying between 40 and 50 Brush lamps. The current is supplied by two Brush dynamos, a 16 and 40-lighter. It says something for Messrs. Hammond's workmanship and care that no accident has yet occurred, although the currents are of high tension, and shows that where proper precautions are taken these currents can be used with safety.

The Edison System on Ships.—We understand that the ss. "Clan M'Arthur," launched this week at Greenock, is to be fitted up by the Edison Company with their system of electric light. In addition to the "Clan M'Arthur," the company have on hand contracts to light up the ss. "Apollo," and ss. "Minerva" at Messrs. Wm. Denny Bros., Denny's Yard, at Dumbarton; the ss. "Pateena," at Messrs. J. and A. Inglis, Pointhouse, and the ss. "Rio Pardo" and ss. "Rio Parana" at Messrs. Caird's yard, at Greenock.

Electric Lighting at Norwich.—The Hammond Electric Light Company, of 110, Cannon-street, E.C., have recently installed 200 Swan lamps in Colman's mustard factory at Norwich. It is intended to increase this number considerably in the future. The current is supplied by a Ferranti dynamo. Mr. Colman has also had his library and drawing room lighted by means of twenty Swan lamps, the current for these being supplied by Sellon-Volckmar accumulators, which are charged during the daytime by the above dynamo machine.

Electrical Patents in the United States.—According to a speech recently delivered by Mr. Edward M. Bentley, one of the examiners in the electricity division of the United States Patent Office, about 2,000 applications for patents relating to electricity were filed in 1882, of which about two-thirds were granted. To show how the subject had grown in importance within a very few years, Mr. Bentley said "that in 1877 electricity was a sub-class in a division. Now it was the largest division in the office and regarded as the most important."

Electric Lighting in Nottingham.—The lace factory known as Player's Mill, Nottingham, is being lighted by means of Swan lamps. This factory is let out in floors to lace manufacturers by the owner, who also supplies them with light and power. Hitherto gas has been employed, but it is now being superseded by the incandescent light, and we believe that the change is universally appreciated by the *employés*. The current is supplied by a Ferranti dynamo, which will feed 500 Swan lamps. The work is in the hands of the Hammond Electric Light and Power Company.

The Lighting of Brooklyn Bridge, New York.—The following estimates have been received by the Brooklyn Bridge Trustees for supplying seventy lights, the price to include engines, dynamos, conductors, and everything except steam. The Arnoux-Hochausen Electric Company, 15,750 dols.; United States Illuminating Company, 18,150 dols.; Schuyler Electric Light Company, 20,000 dols.; Edison Electric Light Company, 21,500 dols.; Brush-Swan Electric Light Company, 23,273 dols.; Fuller Electric Company, 25,455 dols. The matter of decision has been referred to a committee, preference being accorded to the estimate of the United States Company.

The Aquarium Exhibition.—On Wednesday evening what may be called the opening of this exhibition took place. Much progress has been made during the last few days in fixing up the lamps and machines, and the exhibition may be said to be fairly complete. In order that there shall be no lack of the sensational element, Messrs. Paterson and Cooper have fitted up a large arc light at one end, close to the roof; this is said to be of 100,000 candle-power. The current is supplied by an Elphinstone-Vincent machine. There are some prettily arranged rooms lighted by Swan and Edison lamps, and an imitation grotto, all of which well demonstrate the suitability of the lamps for indoor lighting purposes.

Renewal of an Electro-plating Patent.—The Plating Company, of 34, Kirby-street, Hatton Garden, E.C., have given notice that they intend to apply for a prolongation of the terms of letters patent granted to William Brookes, of 62, Chancery-lane, civil engineer and patent agent, for the invention of "improvements in the electro deposition of nickel," a communication from abroad by Isaac Adams, jun., of Boston, Massachusetts, in the United States of America, bearing date the 28th October, 1869, and numbered 3,125, and which letters patent were assigned to the said Plating Company. Notice of opposition to this application must be lodged at the Privy Council Office prior to the 25th April next.

Telegraph Expenditure and Revenue.—An account prepared by the Treasury, on an order by the House of Commons, shows that the gross amount received on account of the telegraph service in the year ended 31st March, 1882, was £1,654,390 13s. 6d., and the expenditure £1,440,498 6s. 10¼d., leaving a balance to meet interest on stock created on account of the telegraph service and the redemption of debt of £213,892 6s. 7¾d. The interest on this capital stock, amounting to £10,880,571 5s. 2d., was for the year to 5th January, 1882, £326,417 2s. 9d., so that there was a deficiency in the telegraph revenue for the last financial year of £112,524 16s. 1d. The total amount of deficiency from 1st January, 1872, to the 31st March, 1882, was £1,330,350 8s. 10d.

Electric Lighting for Hastings.—This favourite seaside resort is likely ere long to have a very compact electric lighting station. We understand that the building itself is already erected, and that arrangements are being made for fitting up two 40-light Brush dynamos, which are to supply current for Brush lamps to be erected on the sea front, in shops and streets, &c. It is intended to have engine power up to 250 horses or more, as soon as the necessary arrangements can be completed, and to start supplying electricity for light and power purposes on a practical scale. The station is in the hands of the Hastings Electric Light Company, which some time since purchased a concession for that district from the Hammond Company. When things are in their place we hope to give a more detailed account, with illustrations, of this station.

A Tangent-Galvanometer for Measuring Powerful Currents.—This instrument, designed by the late F. J. Pirani, M.A., is extremely simple in its construction, and, at the same time, portable and accurate. It consists of a band of copper doubled on itself, and then bent so as to form two concentric circles in one plane of slightly different diameters, through which a current will flow in opposite directions. Suspended at their common centre is a magnetic needle, the deflection of which can be read off by an index traversing a divided circle, or by a mirror reflecting a beam of light on to a scale in the ordinary manner. The leading wires are twisted together to eliminate their effect on the needle. The

Digitized by Google

paper is illustrated by a diagram of the arrangement.—Abstract from the *Transactions* Roy. Soc. of Victoria, appearing in abstracts from foreign publications, &c., published by the Institution of Civil Engineers.

Hail and Thunderstorms.—A correspondent of the *Scotsman*, writing from Prestonkirk on the 8th inst., says:—"About 7:30 a.m. the sky was quite clear. In less than twenty minutes there was a general darkness, followed by a short but severe thunderstorm, during which the lightning was very vivid and near at hand. The storm coming from the north-east, and accompanied by a more than ordinary high wind, sent the hailstones—every one as large as marbles—with full force against all windows with an eastern exposure. At Seacliff nearly 100 panes of glass were rendered useless, and at Newbyth about 200 more, whilst other places in the line of the storm suffered more or less from its effects. The real force of the storm seems to have been between Tantallon Castle and two miles southwards, losing force as it travelled landwards. Many of the hailstones, after two days' exposure, are still to be seen, almost undiminished in size, showing the hardness of their nature. Many birds were found, after the storm had passed over, not only with broken wings, but without life, evidently struck on some vital part by the hailstones."

The United Telephone Company v. Hebden.—This case was heard before Mr. Justice Fry on the 10th inst. It may be remembered that about a fortnight ago his lordship made an order, committing the defendant to prison for contempt of Court, in not obeying an injunction restraining the infringement of the plaintiffs' patent for Bell's receiver, and for the delivery up of instruments. On that occasion the defendant appeared in person; he has since been lodged in prison.—Mr. Renshaw now moved to obtain his discharge on certain affidavits.—Mr. Moulton, for the company, said they left the matter in his lordship's hands, but thought it desirable to point out discrepancies in the defendant's evidence. —Mr. Justice Fry said if the defendant had come here with a simple apology and expression of regret, he should have had no hesitation in discharging him; but instead he had thought fit to file an affidavit with a view to justify and explain his conduct. In his lordship's view, that affidavit was entirely false, and was a repetition of his previous offence—namely, making a false affidavit to deceive the Court. He thought this a similar attempt, and should make no order on this application, except that the defendant should pay the costs.

Underground Wires.—Mr. Monk, M.P., as President of the Associated Chambers of Commerce of the United Kingdom, has forwarded memorials to the Postmaster-General, urging, amongst other things, that in consequence of the frequent interruption of telegraphic communications by storms the Government should take steps to have the principal lines of wire conveyed underground. It may not be out of place to record here the latest dictum on this subject. Mr. W. H. Preece, F.R.S., in a recent paper says, speaking of the Post Office system:—"Wires are almost invariably carried underground through towns. Copper wire insulated with gutta percha encased in iron pipes is the material used. There are 12,000 miles of underground wire in the United Kingdom. There in a great outcry for more underground work in England, owing to the destruction to open lines by gales and snowstorms; but underground telegraphs, wire for wire, cost at present about four times as much as overground lines, and their capacity for the conveyance of messages is only one fourth; so that overground are, commercially, sixteen times better than underground wires. To lay the whole of the Post Office system underground would mean an expenditure of about £20,000,000. Hence there is no desire to put wires underground except in towns. Besides, snowstorms are few and far between, and their effects are much exaggerated."

Accumulators.—In an interesting article on the progress made in the applications of electricity since the Paris Exhibition in 1881, which appeared in last Wednesday's *Times*, and occupied four columns of that paper, the author, after dealing with lamps, dynamos, power transmission, &c., speaks of accumulators. Having alluded to Planté's, Faure's, and the Faure-Sellon-Volckmar batteries, and the respective advantages offered by each, with the methods adopted by the inventors for the formation of the plates, goes on to say:—"Other inventors have produced the lead in a finely divided powder by deposition from the acetate of lead or other means; and by compressing this powder into a compact mass they have obtained sheets of very porous lead. The rapidity with which accumulators made of this material can be "formed" is remarkable, and those who have made experiments on these plates find them to be superior to any others. It seems, then, that after all the excitement which was raised about the Faure battery, we are likely to return eventually to a form which resembles a Planté secondary battery to a much greater extent. It is satisfactory to know that the chemistry of these secondary batteries continues to be carefully studied by Dr. Gladstone and Mr. Tribe, and also by Professor Lodge. Their chief result is that the action observed in these secondary batteries s largely influenced by the sulphate of lead formed by the presence of sulphuric acid in the cell. These researches promise to help greatly in the future development of the invention."

Electric Lighting at the Law Courts.—Lord Chief Justice Coleridge having made complaints of the failure of the incandescent lights in his court on Thursday week, Messrs. R. E. Crompton and Co., the engineers, wrote explaining that it arose from a mistake made by one of the attendants at the courts, who told their men that all the courts had risen, and consequently the lights were turned down as usual previous to their being extinguished for the night. Messrs. Crompton write further that "Lord Coleridge had himself stated in court that he would not sit after 4:30, whereas the jury had not given their verdict until 7:15. Meanwhile the attendant on going his rounds, and seeing no one in the corridors, made the not unnatural mistake of supposing all the courts had risen, and gave the order to turn down the lights. After the mistake was discovered, it was impossible to turn the lights up to their full brilliancy, as the engine driver had let his steam down. There will be no possibility of such a mistake occurring in future. We take this opportunity of stating that, as far as we are aware, there has not been the least hitch or trouble with the electric light since the courts were opened." We do not think the present mistake would have been so serious in its results had Messrs. Crompton had a few secondary batteries ready charged on which to fall back in cases of emergency. The contractors for the lighting of the New Law Courts must remember that such mistakes greatly injure electric lighting in the public estimation, and if they can be guarded against by a little extra care and precaution, such should not be wanting.

"Electric Light in Our Homes."—On Tuesday night Mr. Robert Hammond, of the Hammond Electric Light and Power Supply Company, delivered before a crowded audience at the Highgate Literary and Scientific Institute a lecture upon "Electric Light in our Homes;" Professor Tomlinson, F.R.S., in the chair. A feature of the entertainment was the

Digitized by Google

erection upon the stage of a miniature drawing room, displaying throughout the ordinary surroundings of a home, showing the adaptability of the electric light for home use. The lecturer dwelt at some length upon the fact that all the lighting agents which have been used by man since the very earliest days, from the rough fire of the savage to the gas of the present day, have all had one feature in common, viz., that they have been more or less brilliant, according to the greater or lesser amount of oxygen abstracted from the air, and he stated that if philosophers met together to devise a perfect light, they would consider it essential that the light should be (1) one which should not rob the air of oxygen; (2) nor add noxious fumes; (3) to be capable of sufficient sub-division to avoid affecting the eye unfavourably; (4) and be no element of danger in a house. All these conditions, he stated, were fulfilled by the incandescent lamp. After touching upon the various processes of the manufacture of the lamp, the lecturer dwelt upon the question of conductors, and then detailed the way in which the electric current was produced in the dynamo machine, the way in which this was stored in the accumulators, and the way in which it could be measured in passing into houses from central stations. The "Sellon-Volckmar" accumulators were used for the lighting of the drawing room, and for various experiments during the evening. As hundreds were turned away from the doors, the lecturer promised to deliver the same lecture again at an early date.

Telegraph Instruments.—In a recent lecture, Mr. Preece said, speaking of the telegraph instruments in use at the present time:—"The A B C is the simplest to read, for it indicates the letters of the alphabet by causing a pointer to dwell opposite the desired letter. There are 4,398 in use. Its mechanism is, however, complicated and expensive, and it is being rapidly supplanted by the telephone. The needle instrument is the simplest in construction, but it requires training to work it. There are 3,791 employed by the Post Office, and 15,702 among different railway companies. As a railway instrument it is the simplest, cheapest, and most efficient ever devised. The Morse instrument, of which the Post Office possesses 1,330, records its letters in ink, in dots and dashes on paper tape, and, like the needle and A B C, appeals to the consciousness through the eye. It also indicates the letters of the alphabet by sound, and thus utilises the organ of hearing. Sound-reading is gaining ground in England with great rapidity. There are now 2,000 sounders, while in 1869 there were none. In America scarcely any other instrument is used, but on the Continent of Europe there is scarcely one. Acoustic reading attains great perfection in Bright's bell instrument, where beats of different sound replace the dot and dash of the Morse alphabet. Sound reading is more rapid and more accurate than any system of visual signals or permanent record. The Hughes type instrument, which prints messages in bold Roman characters, is much used on the Continent; it is, in fact, recognised as the international instrument, but it has had to give way in England to a more rapid system of telegraphy. It is, however, solely employed for the Continental circuits by the Submarine Telegraph Company." After describing duplex and quadruplex circuits, Mr. Preece said:—"There are in England 319 duplex and 13 quadruplex circuits at work. The acme of efficiency in telegraphy is attained in the automatic systems, in which manual labour is supplanted by mechanism in transmitting the messages. There are 71 circuits worked by these instruments, and 224 instruments in use, and a speed of working of 200 words per minute is easily maintained upon them. With the hand alone from 30 to 40 words per minute is the maximum rate attained, but by automatic means the limit is scarcely known. Since this system can be duplexed, and in many cases is so, 400 words per minute on one wire are easily sent. By the use of high-speed repeaters the length of circuit for automatic working is scarcely limited; it would be easy to send 100 words per minute to India."

City and Guilds of London Institute.—We have before us the report of the council of this institute, presented to the governors at a meeting held on Wednesday, March 14, 1883. Technical education is a subject of the greatest interest, and one on which there may be various opinions. We have advocated—we shall continue to advocate—the work of the institute, not because we think it is perfect or approaching perfection, but because the work is in the interests of technical education. We shall not this week deal with the report proper, but confine our remarks to the reports of the examiners and the examinations. The examination papers, so far as electrical subjects are concerned, have been given in our columns, and a number of solutions have also been given. Thus, our readers are fairly acquainted with the papers, and, it may be, are in some measure prepared for an adverse report from the examiners. The following are extracts from the reports of the examiners in telegraphy and in electric lighting:—*Telegraphy* (W. H. Preece, Esq., F.R.S., Examiner): "The papers of the competitors in the first class of the Honours examination are of very fair merit. The replies given in the Ordinary, or Pass, examination are not altogether of a satisfactory character, except in one or two cases. The competitors who have taken but a low place in the second class, and those who have not passed, have, in many cases, shown that the knowledge they possess of the subjects they deal with is of a mere mechanical nature, and has simply been attained from constant practice at a particular system with which they have had to deal, and they appear to have but little notion of the broad principles upon which that particular system is founded; thus, for instance, they describe at full length, and quite correctly, the methods of making tests with particular forms of apparatus, but it is quite evident that if these tests had to be made with instruments which were slightly different in character to those described, the experimenter would be unable to carry them out. In one or two instances the answers given have been merely definitions, such as would be found in any technical dictionary. Altogether, I think the character of the papers submitted is superior to those of former years."—*Electric Lighting*—(Professor W. E. Ayrton, F.R.S., Examiner): "The answers to the questions set at the recent Technological Examinations in Electric Lighting and Transmission of Power show that the candidates, with a few striking exceptions, have hardly advanced beyond the mere descriptions of the construction of machines, and have had little opportunity of studying the science underlying their trade. Considering, however, how very difficult it is for students to find men who are competent, and who at the same time have sufficient leisure to teach, the answers in this subject may be regarded as fairly good." Our duty to the public compels us most reluctantly to say it is essential that no professor should act as an examiner. There are few who realise more than we do the great ability and energy of Professors Armstrong, Ayrton, and Perry; but we must distinctly point out that these gentlemen should not be examiners in the special subjects upon which they lecture. It is late in the session to make changes, but the council must make the changes, and should do it at once.

Digitized by Google

ELEMENTARY ELECTRICITY.

VII.

When a metal ball is placed inside a closed hollow conductor, and in contact with it, the ball attains the same potential as the conductor. But Cavendish and Faraday showed that, under these circumstances, the ball lost all trace of electrification. Hence we infer that a body which is inside a closed hollow conductor, and at the same potential as the conductor, is unelectrified, and, conversely, a body which is unelectrified and within a closed hollow conductor is at the same potential as the conductor.

Hence, if a body be placed within a closed, or nearly closed, hollow conductor, and be at a potential below that of the conductor, the body must be negatively electrified, and if it is at a potential above that of the conductor it must be positively electrified. Thus, a metal ball in connection with the earth, and placed inside a nearly closed conductor, which is at a positive potential, will be negatively electrified, while if the conductor is at a negative potential the ball will be positively electrified.

If the capacity of the ball be known and also its charge when in connection with the earth, the potential of the conductor can be determined. Thus, suppose that the hollow conductor has a potential V, and that C denotes the capacity of the ball. Then, if unchanged, the ball would have a potential V when placed within the conductor. It must, therefore, receive a charge sufficient to reduce its potential from V to O, that is, it must receive a charge of $-$ C V units. Hence, if $-$ Q denote the charge found upon the ball, we have

$$-Q = -CV, \text{ or } V = \frac{Q}{C}.$$

This method was adopted by Dellman for measuring the potential of the air. A ball, suspended by an insulating (silk) string, was raised to the point at which it was desired to measure the potential of the air. The ball was then connected with the earth for an instant, after which it was again insulated, lowered, and its charge determined. The capacity of the ball being known, the potential of the air around it at the instant when it was connected to the earth could be determined as above.

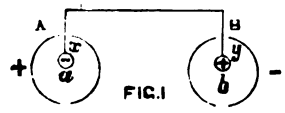

FIG.1

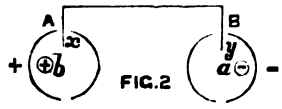

FIG.2

Suppose A and B to be two metallic vessels closed, except for small openings at the top and bottom, and $x\ y$ a wire, whose ends are within the vessels, but which is insulated from A and B. Let $a\ b$ be two small conductors, which can be moved as desired by means of small insulating handles, not shown in the figure. Let there be a small difference of potential between A and B, and for the sake of simplicity suppose that the potential of A is v and that of B $-$ v. First, suppose that a and b are in contact with the ends of the wire $x\ y$, as in Fig. 1. Then, if a and b were unelectrified, a would have the potential v, and b the potential $-$ v. But a and b must be at the same potential since they are connected by a wire. Hence a must be negatively electrified, and b positively electrified. If the capacities of a and b be the same, and are denoted by c, the charge upon a will be $-$ $c\ v$ units, and that upon b will be $c\ v$ units. Now, let a be removed from A and brought into B, and, at the same time, let b be removed from B and introduced into A, as in Fig. 2, and let b be made to touch A, and a to touch B. Then b and a being in contact with the interior of nearly closed hollow conductors will become completely discharged, and the vessel A will receive a positive charge from b, thus increasing its own charge and raising its potential, while B will receive a negative charge from a, increasing its own negative charge, and the numerical value of its potential. The vessels A and B are called inductors; the small bodies a and b are called carriers. If the capacity of each inductor be n times that of each carrier the charge and potential of each inductor will be increased numerically by the operation just described in the ratio of $1 + \frac{1}{n} : 1$ or of $n + 1 : n$.

After the carriers a and b have been discharged, they may again be connected with the ends of the wire $x\ y$, and the whole operation repeated as often as we please, the numerical values of the charges and potentials of each conductor being increased in the ratio of $n + 1 : n$ by each operation. Thus, the charges and potentials increase in a geometrical progression whose common ratio is $\frac{n+1}{n}$. This increase may be continued until the loss due to imperfect insulation, brush discharges, &c., begins to lower the rate of increase, and at length the rate of loss due to such leakage will become equal to the rate at which electricity is furnished by the apparatus, and then all further increase will cease.

The replenisher of Sir William Thomson is identical in principle with the apparatus just described. It consists of two insulated inductors, A and B (Figs. 3 and 4), usually made of brass, and together forming a hollow cylinder except for two spaces, by which the inductors are insulated from each other, and two brass carriers, a and b, supported on an ebonite arm, which is capable of rotation about a vertical axis, O. There are two springs, x and y, which are touched by the carriers when in the position shown in Fig. 3, and which are connected by a wire passing underneath the carriers, and not shown in the figures. There are also two springs, s and t, attached to the inductors, and touched by the carriers when the latter are as far as possible within the inductors.

Suppose, as before, that there is a small difference of potential between A and B, and that A is at the potential v, and B at the potential $-$ v. Let the inductors be in contact with the springs x and y, as shown in Fig. 3. (We shall for simplicity treat the inductors as though they were closed surfaces. This is obviously far from the case, but Sir William Thomson has shown that a small body placed near the bottom of a hemispherical bowl is under conditions differing very little

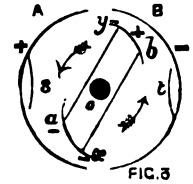

FIG.3

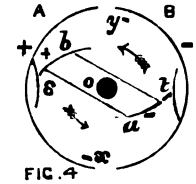

FIG.4

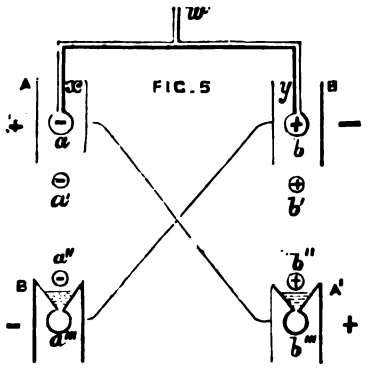
from those of a body placed within a closed conductor. The ultimate effect of the want of closure of the inductors A and B will be merely to diminish the rate of increase of the charges, and will not affect the character of the action.) Then a will be negatively electrified and b positively electrified, since they are in connection with one another, and, if unelectrified, a would have a positive potential (nearly) equal to v, and b a negative potential nearly equal to $-$ v. Now, let the arm supporting the carriers be made to rotate about the axis O in the direction of the arrows. The carrier b, with its positive charge, will then enter the inductor A, and the carrier a, with its negative charge, will enter B, as shown in Fig. 4. Presently the carriers will come into contact with the springs s and t, and thus being in connection with the inductors, while they are also within them, the carriers will give up their charges to the inductors with which they are in contact, the carrier b giving its positive charge to the inductor A, which is already positively electrified, while a gives its negative charge to increase that of the negatively electrified inductor B. After leaving the springs s and t, the inductors, now unelectrified, come in contact with the springs x and y, when a becomes positively electrified and b negatively electrified. The carrier a with its positive charge then enters the inductor A, while the carrier b enters the inductor B, and the operation just described is repeated. Thus, the instrument performs a com-

Digitized by Google

plete cycle of operations twice during every revolution of the carriers, the charges of the inductors being increased in geometrical progression, as in the apparatus before described.

As the carriers pass from one inductor to the other *work* has to be done against the electric forces, for the positively-electrified carrier is leaving the negative inductor which attracts it, and entering the positive inductor which repels it, while the negatively-electrified carrier is similarly being compelled to move in opposition to the forces which act upon it. The work thus done against the electric forces is the equivalent of the increase of energy of the electrified system.

If the ebonite arm be turned in the opposite direction, the carriers which have become electrified by contact with the springs *x y* will be put in communication through the springs *s t* with the inductors, which are electrified in the opposite way to the carriers. Thus the negatively electrified carrier, leaving the spring *x*, will come into communication with the positive inductor A, while the positively-electrified carrier will come into communication with the negative inductor B, and the charges of the inductors will thus be reduced. During this operation the carriers will be moving in the directions in which the electric forces urge them, work will be done by the electric forces, and the energy of the electrified system will be reduced. If the friction could be made sufficiently small the carriers would, when left to themselves, revolve in the opposite direction to the arrows under the the action of the electric forces, thus reducing the charges of the inductors, so long as any considerable differenee of potential existed between the inductors.



Of course it is not necessary that the inductor B should have a potential as much below that of the earth as the potential of A is above it. If the springs *x y*, and the wire connecting them be insulated, the potentials of the inductors may be any whatever to commence with, and the motion of the carriers in the direction of the arrows will increase the difference between them if any exist.

The object in view in designing the replenisher was not to obtain large charges of electricity at the most rapid rate possible, but to increase slowly and almost continuously the charge of a Leyden jar, stopping the increase as soon as the proper limit was reached, and also, in case of over-stepping the limit, to be able to reduce the charge slowly and in an almost continuous manner. These conditions the instrument completely satisfies.

Varley's machine is similar in principle to the replenisher of Sir William Thomson, but preceded the replenisher by several years. The machine was intended for the rapid generation of electricity at high potential. Hence several pairs of carriers were employed, and these, in the form of pieces of tinfoil, were arranged around the circumferenee of a revolving disc of ebonite, while the inductors almost completely surrounded the carriers when the latter were within them.

Fig. 5 represents Sir William Thomson's water dropping accumulator with crossed conductors. In principle it is the same as the replenisher, or the apparatus represented in Figs. 1 and 2, modified only in order that advantage may be taken of the action of gravity upon falling drops of water. Each of the inductors consists of two metal cylinders A A′ and B B′, the cylinders A′ and B′ being provided with small copper funnels, which catch the falling drops of water before allowing them to flow through the small perforations at the bottoms of the funnels. The cylinders A and A′ are connected with a wire so as to form one conductor, and the cylinders B and B′ are similarly connected, but A A′ and B B′ are insulated from each other. A convenient mode of supporting the cylinders is to suspend them by silk twist which has been steeped in melted paraffin, and all four cylinders should be separately suspended from a support considerably above A and B, as the portions of the silk between A and B′ and between B and A′ soon get wet and lose their power of insulation. The wire *x y* of Figs. 1 and 2 is replaced in this apparatus by the water pipe *x w y*, which terminates in two jets within the cylinders A and B. The falling drops of water serve as carriers. Suppose that there is a small difference of potential between A A′ and B B′, the former being at potential *v*, and the latter at potential $-v$. As the drops of water *a b* are formed at the extremities of the jets the drop *a* will be negatively electrified, and *b* will be positively electrified. The negatively electrified drop *a* will then fall into the vessel B′ and give up its charge to the conductor B B′, while the positively electrified drop *b* will fall into the vessel A′ and give up its charge to the positively electrified conductor A A′. Thus, the charges of the conductors will be increased in geometrical progression by each pair of falling drops, as in the cases considered previously. The energy of the electrified system is furnished by the work done by gravity on the falling drops against the electric forces, the drops being attracted by the cylinders A and B which they are leaving, and repelled by the cylinders B′ and A′ which they are approaching. Hence, on striking the funnels the drops possess less velocity than if they had fallen through the same distances and no electric forces had acted. When the difference of potential between A A′ and B B′ becomes very great the drops break up into fine spray, and, each particle repelling the other particles, the streams of spray diverge, and, instead of falling into the vessels B′ and A′, they fall outside them. No further increase of potential then takes place.

To charge a Leyden jar by means of the replenisher, or the water dropping accumulator, the inner coating of the Leyden jar is connected with the inductor A, and the outer coating with B.

The instruments described in this paper are sometimes said to act on "the compound interest principle," because the charges of the inductors are increased in geometrical progression.

A GUIDE TO PRACTICE IN THE SUBMARINE CABLE TESTING ROOM.

No. XVI.

The subject for our present consideration is a capacity test devised by Sir William Thomson, and generally acknowledged to afford more correct results than the ordinary discharge test explained in a former number. In this, as in the latter operation, the cable is regarded altogether as a condenser, and, following the same course pursued in that case, the cable or condenser of unknown capacity is compared with a standard or a condenser whose capacity in microfarads is known. The test by balance, as it is termed, is more complicated than the other, and requires the employment of greater variety of apparatus.

The difference between the two tests may be thus set forth:—In the capacity test by discharge the accumulating quality, or, technically, the electro-static capacity of the conductor (measured by the inductive capacity of the dielectric) in a condenser charged to a certain potential is determined or represented by the amount of deflection produced by discharging it through the coils of a galvanometer, and if we know this capacity, that is, how many microforads it is, we have a standard to which we can compare another condenser, or cable, by trying what deflection it will exhibit when charged to the same potential and discharged through the same galvanometer. Finding that a condenser of, say, $\frac{1}{2}$

Digitized by Google

microfarad gives 300 divisions under certain conditions, we have a comparative proportion when getting, say, 320 divisions from our cable or unknown value condenser with the same conditions. In practice, of course, we should use a shunt, but that is merely for convenience, as the reader has long since fully understood. In the capacity test by balance, as its title indicates, the capacities of the known and unknown condensers are relatively ascertained by the difference of potentials at the two opposite poles of the battery being such that, on uniting the condensers (putting them into conductive communication), and so dividing the charge between them, no deflection is produced when they are discharged through the galvanometer coils. Supposing we had two condensers of equal capacity charged from a battery, one from each of its poles, then if one were connected to one end of the galvanometer coils and the other to the other end, no deflection would be produced, because the opposite charges would be neutralised. Similarly, if we joined the two equal condensers thus charged to the same potential and allowed the charges to mingle, on proceeding to discharge them through the galvanometer no deflection would result, since there is no charge left. But if two condensers of different capacities were charged from the opposite poles of a battery, and brought into electrical communication with each other as before, what will be the result when we proceed to discharge them through the galvanometer? By the way, we ought to say that in both cases we suppose the battery disconnected from the condensers before the latter are joined.

The two condensers being both charged from one battery, one from each pole, the quantities of electricity on each must be equal. But the *density* or quantity per unit of surface is not the same for both. When they are joined together there is a redistribution. We should like to consider carefully the various conditions attending the charging and the various changes in connection with this test. But it would occupy too much space, and may be deferred. Briefly summed up the principle is this. The amount of accumulation in the case of charged condensers, and the effects resulting from various arrangements depend on the resistances of the inductive circuits. In the case of two condensers opposed one to the other, as in this balance test, the potentials on either side are regulated by the same cause, and any alteration of the resistances on either side of the battery must affect the potentials, a difference of which can alone produce a deflection on a galvanometer when attempting to discharge the quantity supposed to result from bringing the opposite charges together.

What we have to arrive at in this test is to cause the potentials at the two sides to be equal, so that no deflection shall result, and having unequal capacities on each side we establish an arrangement of resistances which will compensate for the inequality. The potentials each way must be made equal to the product of the quantities and the resistance on that side. We then have no deflection when discharging the united condensers.

Summing up in familiar mode of expression, in the discharge capacity test the cable capacity is found by comparison with the effect of a known capacity, at two consecutive observations. In the balance test the potentials are equalised by addition of sufficient resistance on either side of the circuit. The idea of the steelyard and the scales may be allowed to apply in this conection.

The appliances necessary for this test are, besides the battery and key, a double-current split key, as explained in the joint test, a discharge key, and a high resistance arrangement, either in the form of a box or what is called a slide resistance. As regards the split key, if it were of the pattern suggested in Fig. 31, No. XIV., a stout copper wire must be fixed to join the two sides, in fact, forming an upper bar. The lower bar only is to remain split for the purpose in view. We require two separate connections for the two battery wires, but want also the means for uniting the two end terminals after they have been each temporarily joined to the lower points by depressing the key pieces. The key is shown in figure. By putting both down, whatever are joined to the terminals are charged from the battery, and on releasing them they rest against the bar, and communication results between the charged bodies by means of this latter (or the suggested wire across). The high resistance, if a slide, consists of a set of coils of equal resistance, either of 100 or 1,000 units each, with a contact piece, which can be slid along the face to any point, thus dividing the whole into two parts, and enabling us to connect any desired proportion on either side of a circuit. If the resistance is in the form of a box, the pointer simply turns on a pivot, the coils being ranged in a circle round it. Suppose, in a resistance composed of ten coils of 100 units each, the pointer were turned on to the terminal of the fourth coil, or rather we should say the fifth, because, to make any proper use of ten equal coils, we must have one more terminal or coil of no resistance in addition to the ten; therefore, the pointer in this case being on the fifth terminal, there would be 600 units on one side and 400 on the other, the pointer being connected with earth. The wires joining the coils to the two sides of the circuit would be one at the first coil terminal and the other at the tenth. The idea is roughly shown in Fig. 38, where the coils, whatever their value, are all equal, the first, however, being of zero resistance. We have not space for a more detailed account of the construction at present. The coils being always of considerable resistance, certainly not less than 100 units generally speaking, and never less than ten, the student will observe that by this arrangement there are no intermediate resistances, as tens and units, available for our purpose, whereas in testing the capacity of a cable we may require a very small amount to perfect a balance of potentials; an unit more or less makes all the difference if our instrument is sensitive. There are two ways of supplementing this requirement. In one of these an additional box or slide is connected with the larger resistances, and consists of a set of smaller coils, each being a certain proportion of one of the former.

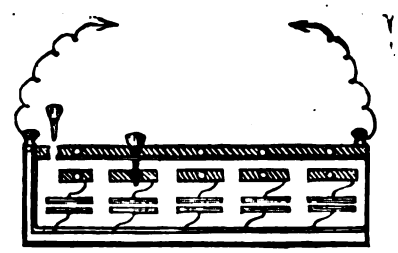


Fig. 36.—Condenser Box.

The learner may know what a "vernier" is on a measuring scale, and will see how this is made to serve the purpose. If there be no such convenience at hand an ordinary resistance-box may be brought into circuit with one part of the resistance already mentioned, and will enable us to arrange our balance. In a well-furnished testing room the high resistance-box (more convenient than a set of slides) will have its accessory box, and the coils in each will be so arranged that, when in performing the operation we have arrived at a balance, the amount of resistance finally marked by the pointers of the two boxes may be read off on the scale on the face of each. For example, if in the high resistance the pointer stood at 52, and in the smaller box at 38, the amount of resistance would be 5,238, from which we find that on one side we have 5,238, and on the other 4,762, the total being 10,000; this has been the proportionate division found necessary to equalise the potentials on each of the battery poles. Where there is no vernier and an ordinary set of coils is employed as just stated, we have only to add the smaller units to the larger, but the arrangement is not so complete.

We will now trace the course of the operation by the aid of Fig. 37, in which are represented the connections for the test in sufficient detail. The condenser, whose capacity in microfarads, of course, is known, is connected to one terminal of the split key, and the cable, whose capacity we want to know, is joined up to the other. The object is to charge the condenser (our standard measure) and the table separately, but exactly at the same instant, for a certain period, say, a few seconds, then to cause the charges to mingle by releasing the key pieces which

Digitized by Google

strike against the upper bar. The *plus* and *minus* charges are in this way divided according to the relative capacities of the condenser and cable. We have then to discharge the whole through the galvanometer, when, if the potentials are equal, no deflection will appear on the scale. Starting from the battery the positive charge will enter the condenser, and the negative charge will pass to the cable. Let the keys be kept down five seconds. At the end of this time they must be released. As both now rest against the upper bar the two end terminals now also connect with it, and through it the charges of condenser and cable amalgamate. If exactly equal they are neutralised. If, as nearly always happens, the cable charge (here *minus*) preponderates, the whole of the *plus* charge is destroyed, but some *minus* charge remains. This is not ascertained until, by depressing the discharge key the remaining charge passes by the lead wire to the galvanometer, and is discharged through it to earth, causing a deflection, right or left as the case may be. The deflection shows that there is a difference of potentials at the two sides of the galvanometer, and of the battery poles, of course. We know from this that the resistances have not been adjusted correctly, and the operation must be repeated after altering them. It is evident that the test will be long and tedious or otherwise, according to the correctness of this adjustment, and it will also depend on other points which must be carefully attended to. In the first place, the relative capacities of the condenser and the cable are matters of interest; we do not know the exact capacity of the latter, but it can be approximately estimated. The average capacity per knot is on record, and, knowing its

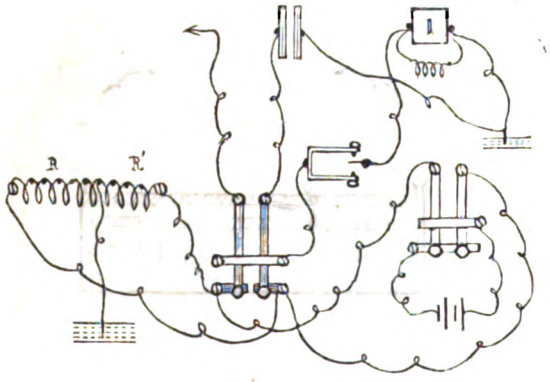

FIG. 37.

length, the total capacity is got at pretty nearly. If it be a very short length we could choose a condenser having nearly the same capacity. The amount per knot is generally $\frac{1}{3}$ microfarad; thus for a length of 10 knots we should choose a condenser of 3 microfarads. When very long sections of cable are in question we can only choose a condenser of a submultiple of its capacity; for 400 knots we might use a condenser of 40 microfarads, if we had one. The object in having a convenient submultiple is, of course, for the adjustment of the resistances.

Another important point is the determination of the amount of resistance to be introduced on each side. It should be noted that the larger these are the better for the purpose, as, if otherwise, the difference of potentials would be insufficient to enable us to measure resistances on the galvanometer. Having, then, a set of the highest coils available, the question arises—on which side is the largest resistance to be introduced? We determined this by observing which of the two—namely, the condenser or the cable—has the larger capacity. Seeing that the difference between that of the two is to be equalised by the addition of resistance on the lesser side, it is clear that if, as is usual, or as it is best to assume, the cable has a larger capacity, the smaller resistance must be inserted on the cable side. For the capacity of the condenser (known), multiplied by the resistance on its side (known), will equal the resistance on the cable side (known), multiplied by the capacity of the cable which we are seeking; that is to say, this is the case when the adjustment has been so made as to cause no deflection when the two are discharged through the galvanometer. One more point is worth mentioning. It is well to know beforehand whether the positive or the negative charge would deflect the spot to the right or left hand. Circumstances often disturb the operation so as to render it doubtful whether the addition or reduction of resistance in attempting to get a balance has really caused the movement in either direction. The effect of the *plus* or *minus* charge, therefore, will then be ascertained by means which, of course, the learner will find no difficulty in adopting. Having arranged these preliminaries, and taken care to connect the earth wires to the proper terminals of the resistance box and the condenser, the test may be commenced. Supposing there is no second resistance box, which we have compared to a vernier, a set of coils for varying the smaller quantities, as tens and units, will be in circuit between the larger set and the split key. The best way to take the test is to use alternate currents; and, even if the first trial, say with the negative battery key down, should prove successful, a second with the opposite pole would be necessary, as the result ought to be the same with both. In the figure the cable is connected to the negative pole when the right-hand key piece is down. The split key is often constructed with a cross piece of ebonite uniting the two key pieces, so that a single pressure puts down both exactly together, which we observe is very important. It is not always quite certain that both are put down exactly at the same instant, though a finger be placed on each, and the same when they are released. A shunt will be useful in any case, and it will be safest to use the largest at the outset; that is, to put the plug in the 1,000 place, the shunt box consisting of a set appropriate to the galvanometer, as explained in an early number, and with coils of 10, 100, and 1,000. By this means the effect on the galvanometer is reduced 1,000 times, $\frac{1}{999}$th only of the current going through it. When a trial or two shows that the balance is near being attained, the others may be used in turn, and finally no shunt, the plug being altogether removed. We will now depress the right hand key and clamp it down. No charge can result while the split key terminals are disconnected from it, but on depressing both key pieces together a charge enters by these terminals both cable and condenser, and will charge each according to the potentials established by their several capacities, and by the resistances on either side of the battery poles. This is allowed to last for five seconds, when the key pieces are released. Then, after five seconds more, during which the charges are mingling, if the discharge key is touched down, and the spot at the same time observed, a deflection right or left will most probably appear. We have now to determine whether to add or reduce on the side on which we have the variable resistance. This depends on which pole originated the charge which caused the deflection. We have previously found this out, and can, therefore, tell whether there is too much or too little in circuit on either side. Of course, whatever we add on one side reduces the other relatively, and *vice versâ*. We must estimate the amount to be inserted or removed, and try over again, but with the other battery pole to cable. In making this reversal the discharge key should be kept down without being released from its last depression, the object being to prevent any interference with the proper discharge of the condenser and

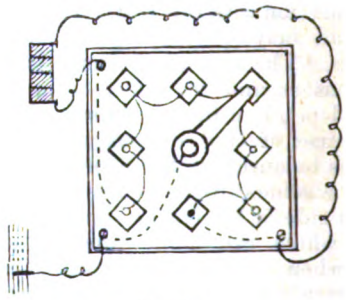

FIG. 38.

Digitized by Google

cable. The operation is repeated with alternate currents until no deflection is produced, when, supposing the last charge in the cable had been, say, positive, one more reversal is to be made, to see if the balance is true with both currents. If so, the capacity of the cable is found by the proportion:—The capacity of the condenser : the resistance on the cable side :: the capacity of the cable : the resistance on the condenser side. Whence the capacity of the cable = the capacity of the condenser × the resistance on its side ÷ the resistance on the cable side. The resistance is in microfarads. We have gone through the test in its complete form, as performed when operating on a submerged cable. At the works, and with short lengths, it is not usual to employ alternate currents. Of course, both *plus* and *minus* charges are in action either way, but the latter only, as a rule, is used for the cable charge. In concluding our remarks on this test for the present, we would point out that in saying the capacity per knot of a cable is about one-third of a microfarad, we speak of it under the unit potential, that is, 1 *volt*, nearly one Daniell cell. We have before observed that capacity is not arbitrary, but must be understood as being of a certain potential. When we use battery power of one volt (say one cell) a knot of cable has a charge of one-third microfarad, but with 120 cells it would have a charge of 40 microfarads. The condenser, however, with which we compare it is credited with so much capacity of unit potential, and that of a cable is related to it as to a general and uniform standard.

The condenser box in Fig. 36 is a convenient arrangement for combining several condensers in a small compass. One of the terminals of each connects with an earth terminal, and the other poles each connect with a brass piece, which can be joined at will to the line terminal by inserting a plug. Any number can be used from 1 up to 20, and, all combined, equal 40 microfarads. In Fig. 38 we have a sketch of a resistance box for dividing the amount on either side of the battery poles. The figures are sufficiently explanatory.

A DYNAMO-ELECTRIC MACHINE.

BY M. J. F. PLUCKER.

The following paper has been abstracted from the *Révue Universelle des Mines*, &c., for September and October, 1882.

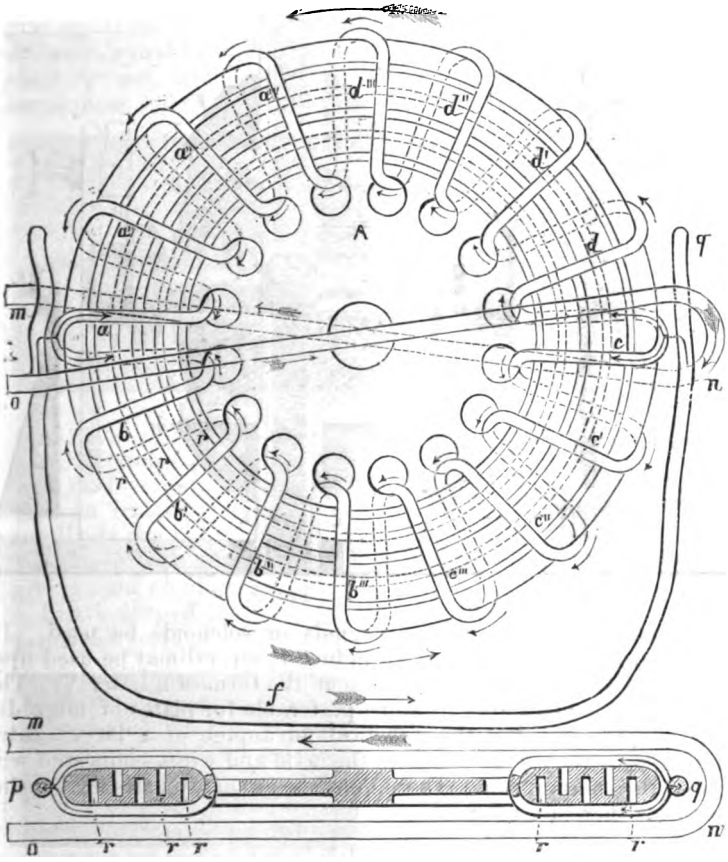

FIG. 1.

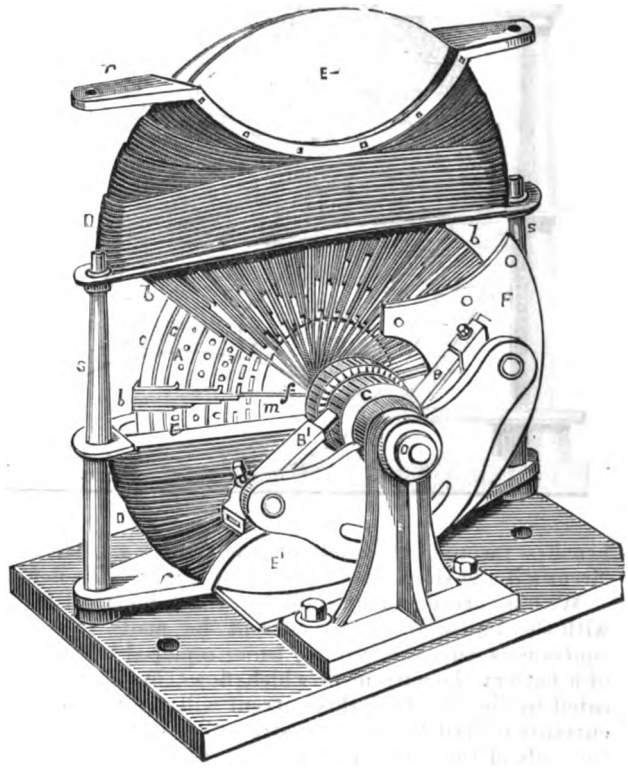

FIG. 4.

The note was communicated by the author to the Antwerp section on May 4, 1882. Although we have not seen one of these machines, we know that a good deal of work has been done in the direction of disc machines, of which this is a type, and it is, therefore, well that the historic continuity of the work in this direction should be placed before our readers. The note is divided into two parts, the first dealing with theory, the second describing the machine. Then, first:—

THEORETIC CONSIDERATIONS.—In Fig. 1, let A represent a disc of soft iron movable around a central axis. This disc may support an insulated copper wire $a\,a'\,.\,.\,b\,b'\,.\,.\,c\,c'\,.\,.\,d\,d'$, wound helically around the periphery of the disc. Further the disc is surrounded by a horizontally wound coil, $m\,n\,o$, connected to a source of electricity, so that the current goes in the direction of the arrows. Under these conditions if the disc is rotated in the direction shown by the large arrows, currents are produced inductively in the continuous wire $a\ b\ c\ d$ in directions which accord with Lenz's law. Thus in the parts $a\,a'\,a''$, upon the front of the disc, approaching the inducing current $o\ n$, the induced current will be of contrary sign to that of $o\ n$, and in a direction from the centre towards the circumference, while the parts $a\,a'\,a''$ upon the back of the disc will have currents of opposite sign to $m\,n$ and in direction from the circumference to the centre; they will increase the potential of the first named currents $a\,a'\,a''$. The portion of the wire on one side of the disc is only influenced by the portion of the inducing current which affects that side, for the disc intercepts, during its magnetisation, the lines of force coming from the opposite side. On the other

Digitized by Google

hand, in the parts *b b' b''* on the front of the disc, which are distant from *o n*, the currents induced will have the same direction as *o n*, and travel from the circumference to the centre. Similarly, the current induced in the back parts *b b' b''* will be of the same sign as *n m*, and will join the currents *b b' b''* in the front. The induced currents produced in *c c' c''* at front and back, and in *d d' d''* at front and back, will add to the potential of the other currents as follows:—The first named to that of *b b' b''* front and back, and the second to that of *a a' a''* front and back. Thus, all these currents go to form two principal currents of opposite sign, the one traversing the upper half of the front of the disc from the centre to the circumference; the other traversing the lower half from the circumference to the centre. These currents become one quantity current when two previously bared points in the continuous wire are connected by a wire *p q* (see horizontal section, Fig. 1);* this conductor should remain in contact with the continuous wire during rotation of the disc; in this way a continuous current will be maintained in it.

The current will evidently be greater and more constant according as the number of coils in the inducing and induced circuits are greater. Therefore, to obtain the greatest effect, the simple coils of continuous wire, shown in Fig. 1, should be replaced by coils arranged like those in a Pacinotti or Gramme ring, that is to say, connected to one another and to the sectors of a Gramme commutator, on which rub two brushes forming the ends of the wire *p q*. The inducing circuits *o n m* should be replaced by a multiple solenoid.

With an arrangement similar to that shown in Fig. 1, and with the disc at rest, if a current be made to traverse the continuous wire, the wire *p q* being replaced by the terminals of a battery the current of which flows in the direction indicated by the arrows *f*, this current will split near *n* into two currents of half the original strength, and these will traverse the coils of the continuous wire in the direction of the induced currents mentioned above, uniting again at *s* to return to the battery. These two currents will act by attraction and repulsion on the current *o n m*, and it is easy to ascertain, by applying Lenz's law, that these reactions will unite to rotate the coils and the disc in an inverse direction to that indicated by the curved arrows. The machine is, in fact, reversible; that is, it can act as a motor or generator.

DETAILS OF THE MACHINE.—A is an iron disc, having grooves pierced with slots, M M, and holes, *t t*, which are utilised for the winding of the coils *b b*. These coils are wound step by step, as shown, so as to cover the face of the disc as completely as possible. The ends of all the wires are carried to the axle O, where they are united in a tubular-shaped bundle, carried through the inducing solenoid D D', and then connected to the sectors of the commutator C'.

Two brushes, B B, rest upon the commutator, and collect the current generated. Rotation is obtained by means of a band upon the pulley *p*. Two soft iron plates, coiled with wire from the inducing solenoids D D, attached to which are two cast-iron wires, *r r'*, a space being left between the solenoids for the axle. The coils are held in position by the iron posts *s s*. Four iron plates, E E' E'' E''', are fixed to *r r' r'*, the whole being retained in position by the pieces F F' F'' F'''. These plates act as magnets, as will readily be understood by considering Fig. 3. At the first onset with this machine it is necessary to have a current from an external source. Afterwards the residual magnetism of the plates E E' E'' E''' suffices.

The inducing solenoid may be replaced by horseshoe electro-magnets, each pole of the latter having a surface equal to three times that of the disc, the arms being wound with wire of the same section, and having a total weight equal to that of the wires constituting the solenoid. It has been found that the results obtained with the solenoid or the horseshoe magnets are sensibly equal, but the solenoid has the advantage of being lighter, and occupying less space.

The machine is stated by the author to act fairly well as a motor, whether electro-magnets or solenoids be used. Instead of a single solenoid inductor, several may be used upon the same plate by giving them the form of a letter V. This arrangement appears to be preferable for plates of large diameter, and has the practical advantage of a large central space for the passage of the axle and wires connected with the commutator. There must be as many pairs of brushes as there are solenoids.

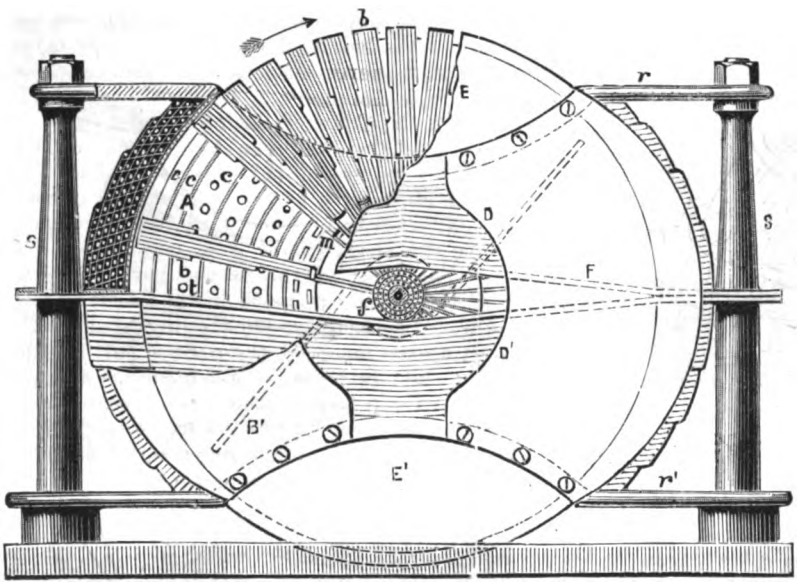

FIG. 2.

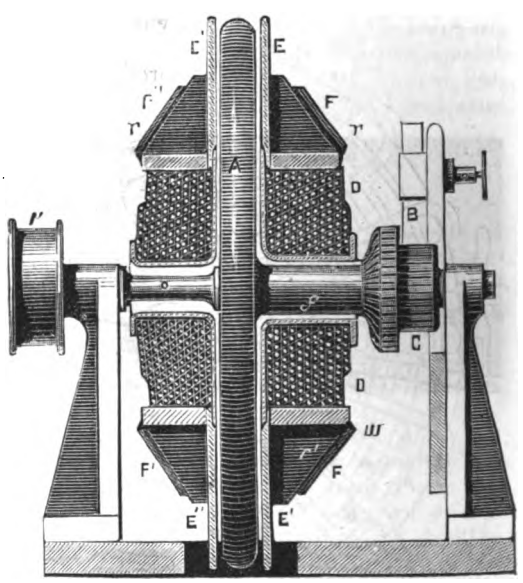

FIG. 3.

* It is only on making connection between these two points that induced currents will be produced during the rotation of the disc; for the effect of the inducing current *o n m* on each half of the continuous wire, above and below the horizontal diameter, being equal and opposite, keeps the induced current in a state of equilibrium, whilst it causes a difference of potential between two points situate on the same diameter, which difference attains its maximum at the horizontal diameter, and becomes *nil* at the vertical diameter.

THE DISTRIBUTION OF LIGHT.

BY J. T. SPRAGUE.

Every one knows that the law of the distribution of light is that it varies as the square of the distance from its point of origin; but it is doubtful how far this law is realised. The reason of the law is purely physical, and it assumes that the strength or intensity of light is subject to the law of quantity. The contents of a sphere, for instance, vary as the cube of the radius or diameter. If, then, we dissolve the same quantity of any substance in the water contained in two spherical vessels, one having double the diameter of the other, the solution in the larger will have only one-eighth the strength of that in the smaller, because the substance is diffused in $2^3 = 8$ times the quantity of liquid. But if a substance is propelled in equal spreading films from the centre

Digitized by Google

of a sphere, it would be no longer diffused in the whole space, but would be successively spread over the enlarging surfaces. Now, the surfaces of spheres enlarge as the square of the diameter, and, therefore, if we spread the supposed equal quantities of substance over the surfaces of our two supposed vessels, the strength of the two films would be as 1 to 4—that is, the diameter being doubled, they would be 1 to $2^2 = 4$.

This is the condition of the propagation of light, which, issuing from a central point, is spread over successive spheri-

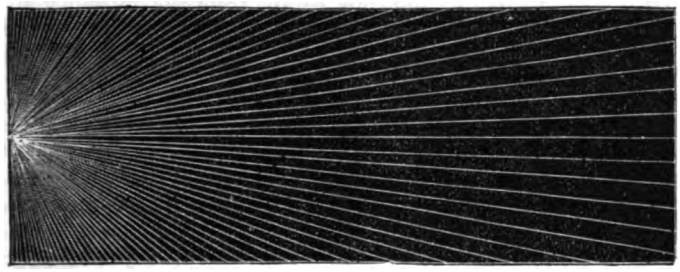

Fig. 1.

cal shells, at each of which the area being as the square of the distance from the centre, the quantity at each point or unit of area must be inversely as the square of this distance.

The practical effect is that as distance increases the power of the light must increase as the square of the distance to give equal effect; that is, if we wish to have light at 10 feet distance, equal to that of a candle at one foot distance, we shall require 100 candles to produce it, but on the other hand these 100 candles will give that light over a spherical

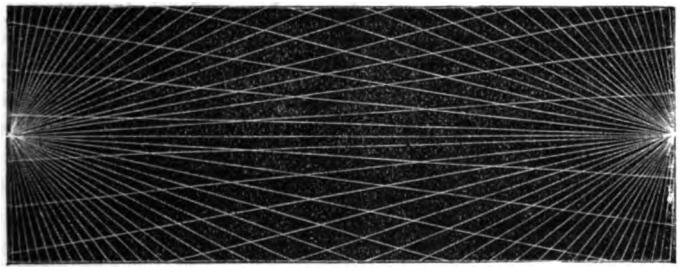

Fig. 2.

area 100 times as great. For most purposes an illumination evenly distributed over a large area is of more value than an irregular light of greater power, and it is better to subdivide the light and distribute it in several sources, which has the further advantage of breaking up the shadows, and giving light on all sides.

I have devised the accompanying diagrams to present these principles to the eye. In Fig. 1 a powerful light is shown at

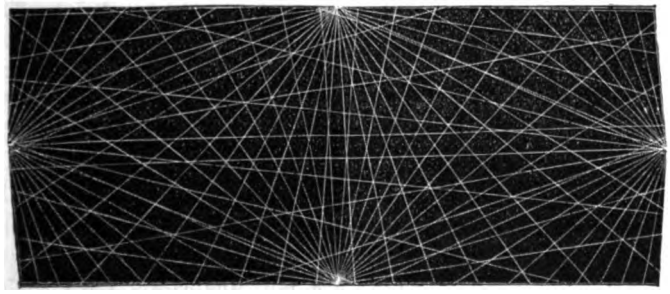

Fig. 3.

one end, and the gradation of the effect according to distance is evident.

In Fig. 2, two lights of half the strength are opposed, so as to equalise their actions.

In Fig. 3, the light is divided into four for the same purpose.

The intention is to show the effect of an equal quantity of light thus divided, and to effect this, each diagram contains the same number of radial lines representing the light. Of course, the intention can only be very imperfectly carried out, because the primary action is generally modified by reflections from walls and ceilings. But this does not materially affect the result, because such reflections themselves operate under the same laws as the direct radiations.

SPECTROSCOPIC EXPERIMENTS WITH THE ARC.*

BY PROFESSORS LIVEING AND DEWAR.

The concentration of the radiation of hydrogen in a small number of spectral lines would lead us to expect that the absorption of light of the same refrangibility as those lines would, at the temperature of incandescence, be correspondingly strong, and that, therefore, the hydrogen lines would be easily reversed. The mass of hydrogen which can be raised to a temperature high enough to show the lines is, however, so small that, notwithstanding the great absorptive power of hydrogen for the rays which it emits, the reversal of the lines has not hitherto been noticed. In fact, the lines are very readily reversed, and the reversal may be easily observed.

When a short induction spark is taken between electrodes of aluminium or magnesium in hydrogen at atmospheric pressure, a large Leyden jar being connected with the secondary coil, the hydrogen lines show no reversal; but, if the pressure be increased by half an atmosphere, the lines expand, and a fine dark line may be seen in the middle of the F line. As the pressure is increased, the dark line becomes stronger, so that at two atmospheres pressure it is very decided. As the F line expands the dark line expands too, and becomes a band. It is best seen when the pressure is between two and three atmospheres; at higher pressures it becomes diffuse, and at five atmospheres it can hardly be traced. No definite reversal of the C line is observed under these circumstances, at least with the one prism spectroscope employed.

By using greater dispersion, the reversal of both C and F may be observed at lower pressures. For this purpose the authors used a Plücker tube, filled with hydrogen, and only exhausted until the spark would pass readily, when a large jar was used. The light of the narrow part of the tube is then very brilliant, while the spark in the broad ends of the tube is wider and less bright. On viewing such a tube end on, and projecting the image of the narrow part of the tube on to the slit of the spectroscope, a continuous spectrum of the width of the narrow part of the tube is seen along with the lines of hydrogen given by the discharge in the wide part of the tube. These lines extend above and below the continuous spectrum, and produce a distinct absorption where they cross it.

The authors (*Proceedings* Royal Society, Vol. 30, p. 157) have observed that the C and F lines of hydrogen are visible in the arc of a De Meritens machine taken in hydrogen; though, in the arc of a Siemens machine the C line can only be detected at the moment of breaking the arc, the F line hardly at all. When, instead of taking the arc in hydrogen, small drops of water are allowed to fall from a fine pipette into the arc taken in air inside a lime crucible, each drop as it falls into the arc produces an explosive outburst of the hydrogen lines. Generally the outburst is only momentary, but occasionally a sort of flickering arc is maintained for a second or two, and the hydrogen line C is visible all the time. The lines (C and F) are usually much expanded, but are frequently very unequally wide in different parts of the line. F is weaker, more diffuse, and more difficult to see than C, and is visible for a shorter time. There is no sign of reversal. In the explosive character of the outburst and the irregularity in the width of the lines the effect resembles that of an outburst of hydrogen in the solar atmosphere. The elements of the water are, as it must be supposed, separated, but from the explosive character of the effect they are not uniformly distributed in the arc. The arc being horizontal, and the image of it projected on to the slit of the spectroscope, it was really a very small section of the arc which was under observation, and this renders the variation in width of the lines the more remarkable.

* Abstract of a paper read before the Royal Society, March 8, 1883, entitled "Note on the Reversal of Hydrogen Lines, and on the Outburst of Hydrogen Lines when Water is Dropped into the Arc."

ANSWERS TO CORRESPONDENTS.

J. P., Gloucester.—You can purchase the apparatus from any of the electrical apparatus makers, such as Clark, Muirhead, and Co.; Elliott Brothers, Johnson and Phillips, &c.

W. T. F.—Shall be glad of your proposed paper; also of any further information with regard to arc lamp in use thirty to forty years ago. The Duboscq (not Buboscq) arc lamp was an improvement on the Foucault lamp; it was one of the earliest arc lamps, and was used at the Opera House, Paris, where M. Duboscq was electrician.

J. G. and others.—We shall always be glad to receive information concerning electric lighting work. Clark's gas lighter, and we believe his induction coil and battery, are made by Messrs. Strode and Co., Osnaburgh-street, N.W.

ELECTRICAL TRAMWAYS.

The problem of electrical locomotion possesses extreme interest for the public at large, and for metropolitan inhabitants especially, just now. To the latter anything that may lend additional force to the protest against experimentally ventilating a public drain, so to speak, into private dining rooms, which is being ostentatiously tried by a London Underground Railway Company would be heartily welcome; whilst to those with whom overtaxed horses are objects of compassion, any hope of ameliorating their sufferings will be highly acceptable. It is notorious that subterranean railway travelling is extremely unwholesome; it ought to be equally notorious that subterranean railways need not be unwholesome. They are dangerous, too, by reason of accumulated steam obscuring the signals; whereas they need not be dangerous at all, for the steam could be condensed if the necessary outlay were incurred. And even if this failed there are other modes of progressive locomotion besides that involving the the use of steam locomotives. Electrical railroads, failing all other expedients, promise an escape from the nuisance and risk attending these now indispensable luxuries of urban locomotion, and the public are anxiously waiting to see this promise fulfilled. As regards tramways, the destruction of horseflesh, caused, it would seem, by the unavoidable strain at every fresh start, is not only very costly but very cruel, and there is an urgent demand in this quarter for something that shall at once relieve the horses from an unnatural effort, and the shareholders' pockets from an oppressive tax.

For all these reasons, and more that might be named, the public are curiously listening to what is now being said about the generating, storing, and transmission of electrical energy, more particularly as touching the matter of locomotion. Naturally, the first serious experiments of a practical kind have been made on the tramcar; at Berlin a considerable length of tramway has actually been working, and we believe answers the projectors' expectations. We need hardly say that the tramway alluded to is not worked by storage batteries. There is a great future before the storage battery, we are assured on very high authority, and we quite believe it, only perhaps we differ as to the character of its greatness and the distance of its future. Still, we are interested in every experiment made with this much-abused system, and sincerely admire the indomitable energy of the people engaged in promoting it. Last Saturday a trial was made on the tramroad between Kew and Uxbridge-road—a trial in which the battery of one of the companies which have taken up the storing of electricity for commercial purposes was put to the test as a substitute for horse-power. From one point of view it was not a success, but as drawing attention to the subject, and as pointing the obstacles that have yet to be overcome before complete success is achieved, the result was as good as could be desired.

Except as a public advertisement—we use the word in its broadest sense—the trial was, indeed, hardly worth making, for a similar one had already been made at Paris, and a satisfactory trial had been given to the system here over the Acton line for the benefit of the Board of Trade officials. The trial on the Kew line was not so successful, owing to the car not being adapted to the change of gauge, which, though comparatively small, was sufficient to cause the rails to act as an effective break on the wheels.

Glancing over the public announcement of the company in question, however, we are struck by the aptitude of the authors for turning figures to useful financial account, and their apparent inaptitude for appreciating precisely those practical difficulties which are not financial. Each horse-power of the steam engine, the public are informed, costs a halfpenny per hour; the electricity stored amounts to 50 per cent. of the energy expended, and will cost, therefore, one penny per hour. This gives as the total cost six shillings per working day, against twenty-six shillings—we quote the figures before us—expended on animal horse-power at present. There is left, therefore, a big margin for intending investors. What is left for the batteries themselves is not stated, for the reason, perhaps, that nothing is yet certainly known as to the life of these mysterious agents. And yet,

Digitized by Google

when speed and certainty have been thoroughly attained, which can hardly be said to be the case as yet, cost of maintenance and renewals is everything, and this is not covered by what the prospectus euphemistically calls "depreciation" and "contingencies." We are bound to look at the worst side of all electrical applications, and to point out conditions that do not seem to have been sufficiently considered.

One of the most encouraging features of this gathering was the speechmaking. Fully reported they are calculated to have an inspiriting effect upon what Mr. Edison calls "my stockholders." From the scientific point of view, unfortunately, their value is somewhat diminished by the circumstance that they were delivered before the trial was made, not after. Dr. Siemens being present, he was described as a person who knew a little about electricity, a joke which provoked much laughter, and which was justified by his own speech immediately after, in which he dilated fluently upon electricity, but reservedly on the subject of storing it. Another speaker stated that one of the greatest difficulties the company had to contend with was the storage department, a remark which, if not meant as a contribution to the facetiæ of the occasion, had certainly the merit of being droll. On the subject of electrical locomotion generally, however, some sensible and instructive observations were made, and these especially may have a wider circulation, we trust, and exert more influence on public opinion than the particular occasion of their delivery perhaps entitled them to. The transmission of power is said by Mr. Edison to be far more profitable than the providing of light, and it has so often been remarked that something was wanted to enable man to use the now wasted natural powers existing to an enormous extent, that there is far greater real interest and thought given to this application of electricity than is ordinarily understood.

GUSTAVE TROUVÉ.

Sterne's theory of the influence of names upon pursuits is certainly borne out by the case under notice. Surely never was a happier name for an inventor than Trouvé (found), almost a literal translation of the Greek sage's exclamation "Eureka!" on making his grand discovery.

M. Gustave Trouvé, whose portrait is appended, was born at Lahaye-Descartes, in the Department of Indre-et-Loire, France, on January 1, 1839, his family being well and honourably known in Touraine, although not connected with scientific investigations. From his earliest years young Trouvé showed great aptitude for drawing, mathematics, and mechanical work. At the age of seven, with the aid of some hair-pins and pieces of metal, he made a working model of a steam engine, with an old powder canister for boiler. Commencing his studies at the Chinon College, he afterwards followed the curriculum of the Ecole des Arts et Métiers, at Angers. At the age of 20 he entered the workshop of one of the leading clock and watch makers of Paris. In 1866 M. Trouvé started a small mathematical instrument factory in the Rue Thérèse, Paris, a street which is now demolished. Here his ingenuity of resource and skilful workmanship soon brought round him some of the first scientific men of the day. He was also in constant relations with the leading physicians of Paris. It was at the instigation of one of them, Dr. Gavarret, that he conceived and completed in three days the electrical instrument for determining the position of, and extracting bullets lodged in the human body. This instrument, with the electrical polyscope for enabling surgeons to see into the throat, the eye, &c., of a patient, secured for M. Trouvé, in 1875, the Barbier prize of the Paris Faculty of Medicine; and in acknowledgment of his valuable contributions to the Paris Electrical Exhibition of 1881 he was made Chevalier of the Legion of Honour.

The following is a list, in chronological order, of M. Trouvé's principal inventions:—

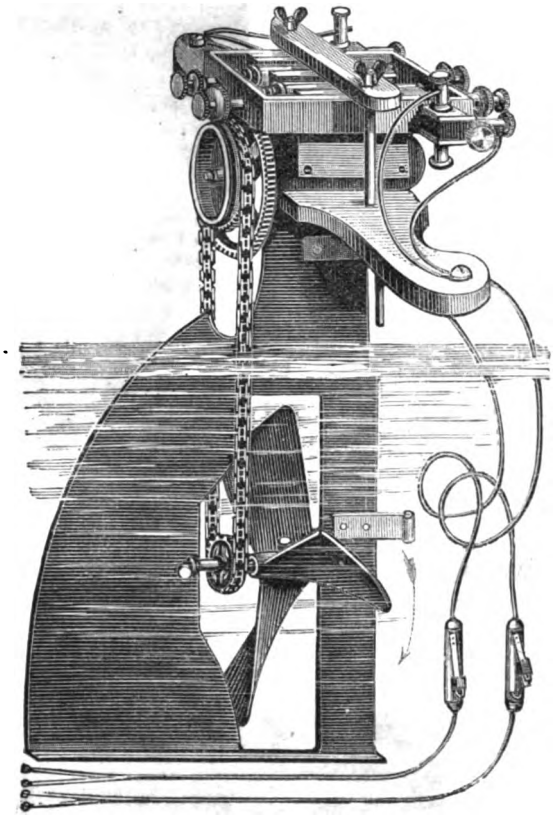
1. Time-piece escapement, beating the second or half-second at pleasure, without the necessity of varying the length of the pendulum.

2. Double-action electro-spherical motor (1864). This motor demonstrates experimentally Newton's law, that action is equal to reaction, and force to resistance. It is now used to demonstrate the reactions which take place in Crookes's radiometer.

3. Hermetically sealed battery, that may be turned upside down (1865). This invention was brought under the notice of the Academy of Science, on December 9, 1867, by M. Becquerel, and before the Academy of Medicine, on June 8, 1869, by M. Béclard. This battery has been applied by its inventor to a large number of special applinaces.

4. Electrical gyroscope (1865), made at the instance of M. Léon Foucault.

5. Electro-medical pocket case for surgeons (1865), brought before the Academy of Science on December 9, 1867, and the Academy of Medicine on June 8, 1869.



Trouvé's Electric Motor attached to Rudder.

6. Apparatus for determining experimentally, and instantly, the best angle of inclination for a screw propeller of given power (1867).

7. Pocket polyscope and electrical polyscope (1869) mentioned above.

8. Electrical explorer and extractor of bullets (1869). This instrument detects the presence, in the tissues of the body, of any substance metallic or non-metallic, and indicates the direction it has followed, its depth, and whether it is covered or uncovered.

9. Appliance for aërial navigation, by means of an artificial bird and a system of two parachutes, brought before the Paris Academy of Science on December 2, 1870.

10. Military telegraph (1870). This apparatus, which may be carried on the back like a knapsack, inaugurated a new system of military telegraphing. It was brought by M. du Moncel before the notice of the Société d'Encouragement, on May 10, 1872.

11. Trouvé-Onimus Appliance (1871), presented by Dr. Gavarret to the Academy of Medicine on January 13, 1874. This appliance, intended for physiological investigations,

indicates the number of intermittences of an electric current in a second, and affords the means of regulating this number, instantly and at pleasure, correct to a hundredth part of a second.

battery, more constant than that of Daniell, is employed in telegraphy and therapeutics, as well as for electric clocks and the recording apparatus at the Paris and Montsouris Observatories.

Portrait of M. Trouvé.

12. Wet battery and constant and continuous current pparatus (1873), brought before the Academy of Science by M. Becquerel on December 29, 1873, and before the Academy of Medicine by Dr. Gavarret on January 13, 1874. This

13. Dynamo-electrical or magneto-electrical machine (1875).

The "Eureka" at Troyes Regatta. Driven by Trouvé's Motor.

14. Pocket electro-medical apparatus for regulating intermittences, presented in 1876 to the Academy of Science by

Digitized by Google

M. du Moncel, and in 1877 to the Academy of Medicine by Dr. Gavarret.

15. Appliance for demonstrating the manner in which muscular contraction takes place, brought by Dr. Onimus before the Biological Society of France on July 6, 1877.

16. Telephone with multiple diaphragms and voltaic arc, brought before the Academy of Science, November 26, 1877.

17. Electrical motor without dead points and capable of being reversed, brought before the Academy of Science on July 5, 1880.

18. Application of electric motor to navigation. A pleasure boat, driven by electricity, was made to easily stem the current of the Seine on May 26, 1881.

19. Electrical tricycle, capable of making 15 kilometres (nine miles) an hour, submitted to the Academy of Science on August 1, 1881.

20. Application of the Trouvé electrical motor to M. Tissandier's balloon, brought before the Academy of Science on August 1, 1881.

Among M. Trouvé's minor inventions should be named his electric bit for stopping runaway horses, his *porte-caustique universel*, and his electro-mobile jewellery.

M. Trouvé also submitted to the Academy of Science, on August 8, 1881, his investigations as to the best conditions for the construction of powerful magnets. He has, moreover, devised a method of electric lighting for domestic purposes, in which candles may be substituted for incandescence lamps, in case the current should fail.

Perhaps the most prominent of M. Trouvé's labours is his application of electricity to navigation, illustrated by the annexed engraving, which represents the electrical boat, the "Eureka," taking part in the Troyes Regatta, on August 6, 1882, and easily distancing a four-oared gig. The electricity is generated by a 6-cell Trouvé battery, in which a winch permits of the elements being more or less immersed in, or completely withdrawn from, the exciting liquid, consisting of 1 part of bichromate of potash, $3\frac{1}{2}$ parts of sulphuric acid, and 8 of water. The current is led through the tiller ropes (which consist of twisted wires, covered with silk and cotton, and encased in an india rubber tube) to the "*gouvernail moteur propulseur*," or combined rudder, motor, or propeller, an enlarged view of which is appended. The Trouvé electrical motor, consisting of a modification of the Siemens coil, is placed in the rudder head, while the propeller revolves in a slot in the rudder itself, motion being communicated by an endless chain. This arrangement intensifies the action of the rudder, so that the boat can turn almost on its own centre, thus rendering a reversing motion unnecessary. The tiller ropes are provided with contacts, so that the steersman can instantaneously stop and start again. By taking off the rudder, which can be carried under the arm, the boat is deprived of its means of propulsion, a useful quality in the exploration of new countries. The facility with which his electric boat can be manœuvred was practically demonstrated by M. Trouvé on the basin of the Palais de l'Industrie during the Electrical Exhibition of 1881, and we may add that more than three hundred boats on this system have been constructed in two years.

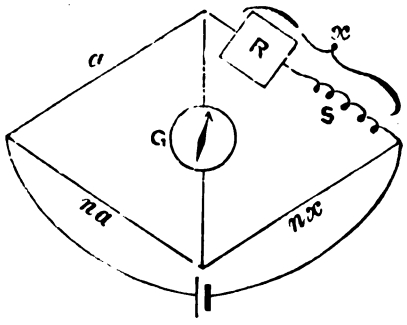
ON A METHOD OF MEASURING ELECTRICAL RESISTANCES WITH A CONSTANT CURRENT.*

It sometimes happens that the resistance of a body appears to depend upon the strength of the current which traverses it. This is the case, for example, with the carbon filament of an incandescent lamp, with selenium, with mixtures of sulphur and carbon, and with microphonic contacts. Without assuming that these are altogether true resistances, it is, nevertheless, sometimes convenient to treat them as such, and for purposes of comparison it is clearly necessary that currents of known or constant strength should be used in their measurement. When the Wheatstone bridge is employed in the usual manner, the current passing through the unknown resistance will, of course, depend upon the magnitude of this resistance, but by a simple modification of the common arrangement it is is easy to ensure having currents of uniform strength throughout a series of measurements. In the figure, x, nx, a, na are the four arms of a Wheatstone bridge, S is the unknown resistance, and R is a box of resistance coils which is inserted in the same arm. If E denote the electromotive force of the battery, B its internal resistance, and C_1 the current which passes through the arm containing S, then, when there is a balance,

$$C_1 = \frac{n}{n+1} \times \frac{E}{B + \frac{n(a+x)^2}{a+x+n(a+x)}}$$

$$= \frac{nE}{(n+1)B + n(a+x)}$$

From this expression we can find what value x must have in order that the current through the unknown resistance may be of any definite strength. Having determined this value, we insert resistance equal to n times its amount in the arm nx, and adjust the resistance of R until a balance is obtained. We then know that the resistance of R + S is equal to x, that the resistance required to be measured, S, is $x - R$, and that a current of the desired strength, C_1, is passing through it. A second unknown resistance may now be substituted and measured as before, simply by altering the resistance of R, with the certainty that when there is a balance the current is of the same strength as in the former



case. The resistance nx remains unchanged throughout. It is, of course, necessary so to choose the values of a, n and E, that x may be greater than the resistance to be measured.

Suppose, for example, that the electromotive force of one battery is 5 volts, its internal resistance 4·5 ohms, that $a = 10$ and $n = 100$, and that we desire a constant current of $\frac{1}{10}$ ampere. Then we shall have

$$\frac{1}{10} = \frac{500}{101 + 4{\cdot}5 + 100}(x + 10)$$

whence

$$x = 35{\cdot}455$$

$$= 35{\cdot}46 \text{ nearly.}$$

We therefore put a resistance of (35·46 × 100 =) 3546 ohms in the branch nx, and vary the resistance in the box R until the galvanometer indicates a balance. It is evident that the resistance of R and S together ($= x$) is then 35·46 ohms, and that a current of $\frac{1}{10}$ ampere is passing through them. In order to find the resistance of S alone it is simply necessary to subtract from 35·46 ohms the unplugged resistance in R.

The great advantage of this method over others that suggest themselves lies in the fact that since it is never necessary to close the circuit for more than a moment the E.M.F. and resistance of the battery remain sensibly constant during a long course of experiments.

* Abstract of a paper read at the meeting of the Physical Society, March 10th, 1883, by Shelford Bidwell, M.A.

Digitized by Google

CORRESPONDENCE.

AYRTON AND PERRY'S ERG-METER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The proof of Mr. Shoolbred's paper, which was put in my hands at the meeting, contained the theory of the Ayrton and Perry erg-meter, and I was not aware, until seeing the letter of your correspondent last week, that the theory had not been explained by Mr. Shoolbred. The fixed coil repels the moving coil, which is the pendulum bob, but the repulsive force in any position of the pendulum is only a very small fraction of the force due to gravity. The repulsion between the two coils for any position is proportional to the product of the currents flowing in them, and as through the fixed coil the main current flows, and the ends of the moving fine wire coil are attached to the supply and return cables of a house, and the current which circulates in the fine wire coil is proportional to the difference of potential between the supply and return cables, for any position of the coils, the repulsion between them is proportional to current multiplied by difference of potentials; that is, the electrical horse-power given to the house. Mr. Shoolbred proceeds to say:

"If c be the current passing into house and v the difference of potential of supply and return cable, then $c\,v$ is proportional to the electric horse-power given to the house.

"Now, the time of vibration of the pendulum is

$$t = \pi \sqrt{\frac{M}{g - k\,c\,v}}$$

if the magnetic force is a retarding one. M, g, v π are constants—so if that the time of clock, when no electricity is passing, be called T, then $\frac{T}{t} = \sqrt{\frac{g - k\,c\,v}{g}}$.

"Now, care is taken that the electro-magnetic forces are very small in comparison with gravitation forces acting on the pendulum bob; so that, to a degree of approximation which is sufficiently correct in practice, the above equation becomes $\frac{T}{t} = 1 - \frac{k}{2\,g}\,c\,v$. The rate of loss in the clock is, therefore, represented by $\frac{k}{2\,g}\,c\,v$. That is, it is proportional to $c\,v$, the electrical power. Hence, the total loss of the clock during any time represents the total electrical energy given to the house during that time."—Yours, &c.,

JOHN PERRY.

WANTED, A PORTABLE LAMP.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I would be thankful if you, or some kind correspondent, would describe an electric lamp to be used by musicians to read their copies while marching out at night.

I notice in this week's *Electrician*, March 10th, page 387, a paragraph upon induction coils, portable batteries, and electric lights, the title of a paper read by Mr. C. J. Clark, in which there is mention of a gentleman who showed an electric light burning in his scarf pin, being supplied from a small portable battery carried in the waistcoat pocket.

Would such a light answer my purpose? as, if so, a description of the different parts would oblige.—Yours, &c.

ONE IN THE DARK.

THE BEHAVIOUR OF CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Can you, or any of your readers, explain the following for me:—How does the current in an external circuit of homogenous character behave? I read in S. P. Thompson's "Electricity and Magnetism," p. 178:—"(A) The magnetic and chemical action of a current are proportional;" and in Clerk Maxwell, p. 292, Vol. I., "(B) The strength of a current as thus measured (*i.e.*, by voltmeter) is the same at every part of the circuit."

How is this reconciled with (C) C. Maxwell, p. 295, Vol. I., sec. 241 (9 v.)—"If by means," &c.? . . . .

Now, from these extracts, it appears that either the E.M.F. of the circuit varies each inch (C) or it does not (B).

Now, $C = \frac{E}{R}$ in any section or for the whole line. The current by (B) does the same work at any point. Resistance certainly does not decrease, ∴ E cannot diminish. In any similar sections the numerical values of $C = \frac{E}{R}$ must be equal.

No doubt some stupid misreading bothers me, but I cannot see it.

The Diagonal Slitting of Commutators.

What, again, is the virtue of the diagonal slitting of the commutator in a Siemens H armature machine? All other (multiple coil) machines are content with parallel bars.—Yours, &c.,

W. T. F.

March 14, 1883.

IMPROVING A DYNAMO MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We beg to enclose you a letter for publication from Messrs. W. Hope and Sons, Leith.—Yours, &c.,

J. E. JACKSON, Manager.

The Electric Carbon Storage and Apparatus Manufacturing Company of Scotland (Limited), Exchange-buildings, Leith, March 12, 1883.

[Copy.]

"Leith, March 12, 1883.

"This is to certify that, having placed in the hands of Dr. Paget Higgs, Electrician to the Electric Carbon Storage and Apparatus Manufacturing Company of Scotland (Limited), a dynamo machine capable of running as per maker's instructions 14 lamps of 15 candles each at a speed of 1,300 revolutions per minute, this machine has been made by most simple means to run constantly 15 lamps of 20 candles each at a speed of 950 revolutions, being an increase of 43 per cent. in lighting power, with a decrease of 27 per cent. speed.

"The machine had been supplied to us by one of the largest and most noted companies.

(Signed) William Hope and Sons."

THE RESISTANCE OF COPPER WIRE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I shall be greatly indebted to you if you will kindly assist me respecting the following:—

In "Electric Illumination," by J. Dredge, page 328, I find the following:—

(No. 1.) "The resistance of a wire of pure copper, 1 mill. in diameter and 1 kilometre in length, is 20·57 ohms at 0° C."

Then follows a formula based on the above statement.

On page 15, *The Electrician*, Vol. 10, in the answer to question 5, there is the following statement:—

(No. 2.) "One foot of hard drawn Cu wire, 1 mill. diameter at 32° F., has R = 9·940 ohms."

As 0° C. = 32° F., and as 1 kilometre = 3,280·8ft., ∴ the *statement* from "Electric Illumination" may be re-stated as follows:—

(No. 1.) 3,280·8 feet of pure Cu wire, 1 mill. in diameter, at 32° F. has R = 20·57 ohms.

My difficulty is that I cannot make statement No. 1 agree with No. 2, nor anything near it. I was employed the other day a very considerable time in trying to work question No. 5 (as above referred to) from the data of the formula in "Electric Illumination," without success. I therefore beg to ask

Digitized by Google

you to point out the discrepancy in the two statements, if any exists, with the correct formula.

Clark's Induction Coil and Battery.

Respecting Mr. C. J. Clark's small induction coil and portable battery mentioned on page 387 of *The Electrician*, March 10, I shall deem it a favour if you can assist me with answers to the following:—

1. Whether they are now manufactured for sale?
2. If they are, where can they be purchased, and what is the price?
3. The postal address of the above Mr. C. J. Clark.
4. Where could I see a full description of the construction of Clark's (C. J.) coil and battery?—Yours, &c.,

JAMES GRUNDY.

[You will find an answer to your question under "Answers to Correspondents."—ED. *E.*].

SAFE WORKING CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. Forbe's letter in your last issue, I beg to give the method by which the figures for safe working currents in *The Electrician* supplement were arrived at.

The method employed is that of calculating the work done in heating a conductor by passing a current through it. Thus:

$C^2R \times 44{\cdot}24$ = number of foot lbs. per minute,

or $\dfrac{C^2R \times 44{\cdot}24}{772 \times 60}$ = number of units of heat per second.

Taking the unit of heat as the quantity of heat required to raise 1lb. of water 1°F., and taking the specific heat of copper as ·0949, one unit of heat will raise 5·854lbs. of copper 1°C. Hence:—

$$\text{Rise per second in degrees C.} = \frac{C^2 R \times 44{\cdot}24 \times 5{\cdot}854}{772 \times 60 \times W}$$

$$= \frac{C^2 R}{W} \times {\cdot}00559 \quad . \quad . \quad (1),$$

W being the weight of the conductor, the resistance of which is R.

Next it is *assumed* from practice that an ordinarily insulated cable, composed of 19 strands of No. 19 B.W.G. copper wire, will *safely* carry 50 amperes. Then

$$\text{Rise per second} = \frac{(50)^2 \times {\cdot}098}{30{\cdot}2} \times {\cdot}00559 = {\cdot}045°\text{C.}$$

Substituting in (1) and multiplying out

$$C^2 = 8\frac{W\ (\text{in lbs.})}{R\ (\text{in ohms})} \text{ approximately.}$$

This formula was calculated for private use, and has been very serviceable, although it probably gives results very considerably on the safe side, and, of course, is only applicable to comparatively short lengths of conductors, in which the question of resistance and economical working does not enter. I hope this subject may now be thoroughly ventilated by your correspondents.—Yours, &c., W. B.

7, Bute-street, South Kensington.

AN ARC LAMP TO BURN AT ANY ANGLE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I beg to inform you that the communication from me in reference to the above does not refer to that devised by Mr. Oliver H. Kenny, and that its working principles are in quite a different direction. Mr. Kenny's lamp contains at least ten electro-magnets, and a great deal of complication, while the lamp invented by me contains one electro-magnet and a solenoid. This works or operates a very simple clutch, in which the carbons are made to approach or recede as circumstances may require. The lamp may be turned upside down, or put at *any angle*, without requiring the least adjustment, and will maintain an arc proportional to the E.M.F. or current passing. It will regulate or feed in the midst of dust without a flicker or any perceptible movement in the light whatever. If there is any doubt attached to this I will exhibit the lamp to those interested, and challenge Mr. Kenny to do the same.—Yours, &c., R. BOWMAN, Patentee.

Cadby's Steam Works, Leather-lane, E.C.

NEW TELEPHONE TRANSMITTERS.*

BY J. MUNRO, ASSOCIATE.

It was during the well-known telephone trial of last summer† that I began to think of getting out a new transmitter. In order to be a novel instrument, and avoid clashing with the Edison and other patents, it was necessary that a new transmitter should fulfil certain conditions; and my connection with the trial showed me what these conditions were.

The broad claim of the Edison 1877 patent is for the combination of a tympan, or drum, with a "tension," or, as I would rather call it, a "current" regulator of semi-conducting material. The particular material used by Edison was lampblack, a form of carbon; but the claim has been held in courts of law to embrace all kinds of carbon, and might even be extended to all so-called "semi-conductors."

Since the memorable discovery of the microphone by Professor D. E. Hughes, a great many patents have been taken out in England and abroad for carbon transmitters of one form or another; but the supremacy of the Edison patent has in general paralysed these efforts, and rendered the improvement worthless. It is even doubtful if the substitution of protosulphide of copper for carbon by Mr. Moseley, in a recent transmitter, will be clear of the Edison claim, since that salt is a semi-conductor.

I determined, therefore, to keep clear of semi-conductors altogether, and, if possible, too, of tympans. The transmitters which I have the honour of bringing before you to-night are made of metal—that is to say, the current-regulator is formed of conductors, so arranged as to render a tympan unnecessary.

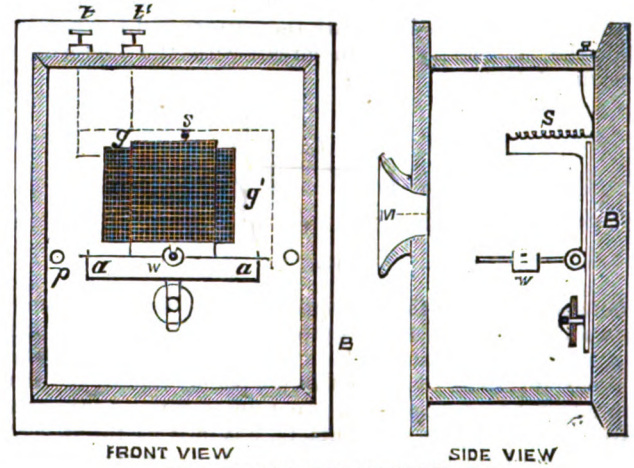

FIG. 1.

Some experiments I had occasion to make in the course of the telephone trial showed me the promise which lay in metals as a material for transmitters—a promise first discovered by Professor Hughes in his microphone researches, but neglected by electricians because of the apparent advantages of carbon. I did not believe that the action of the microphone was due to diminution of resistance at the points of contact, by pressure causing greater or less area of surface contact, according to the current theory at that time. It seemed to me that the film of air between the contact points played an important part in its action, and that the electrodes of a microphone might be of any conducting substance—for example, metals—without destroying its peculiar power of transmitting sounds. I thought, in short, that the current passing through the air between the loose contacts made the sensitive part of the microphone, and that sound-waves traversing this film of air would transmit themselves whether the electrodes were conducting or semi-conducting, carbon or metal.

What kind of metal to use and what particular form to give it, in order to get good articulation and durability of

* Paper read before the Society of Telegraph Engineers and of Electricians, on Thursday, March 7, 1883.

† The United Telephone Company *v.* Harrison Cox-Walker.

Digitized by Google

action, were questions which only experiment could answer. In working out my ideas on the subject, I had a very able colleague in Mr. Benjamin Warwick, whose zeal in these experiments has been unflagging.

Mr. Munro here described his experiments in detail. Continuing he said:—

The use of wires in these experiments led me to the idea of employing two light wire gratings resting on each other under slight pressure, and forming a metal microphone with multiple points. It seemed that the light open structure would allow the sound-waves to agitate the contacts without the intervention of a tympan, and something after the manner of an Æolian harp.

Fig 1 is a transmitter made on this plan. It consists externally of a wooden box, B, having a mouthpiece, M, closed by a piece of match-wood. Inside the box is the microphone, or "current-regulator," which consists of a piece of ordinary iron-wire gauze, *g*, lightly pressed against another piece, *g'*. The back piece of gauze *g'* is fixed to the back of the case, but the front piece *g* is carried by a loose axle, *a a*, supported in bearings at each end. From the axle projects an arm carrying a movable counterweight, W, and the downward pull of this weight tending to lift the front gauze off the back is balanced by the force of an adjustable spring, S. The pressure on the microphonic contacts is regulated by this means. The stops *p p* serve to limit the sidelong play of the axle carrying the movable gauze when it is found convenient to shift the position of the latter in adjusting the instrument.

The current enters and leaves the regulator by the terminals *t t'*. A small induction coil (not shown) is usually inserted between the transmitter and the line, the "primary" of the coil being in circuit with the battery and the regulator, while the "secondary" is in circuit with the line wire and receiving telephone.

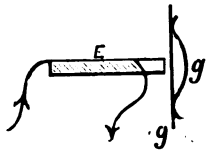

Fig. 2.

On speaking into the mouthpiece in the usual manner, the air-waves set up by the voice pass through the two gauzes, and agitate the contacts between them, thereby modifying the current so as to make the telephone repeat the words. The match-board diaphragm is not an essential, as the sound-waves act directly on the contacts, but it is useful in screening the regulator from the rudeness of the breath, and fixing the distance at which the speaker should keep. A grating across the mouthpiece answers almost as well. In another form which we have constructed, the sound-waves are reflected upon the regulator by an acoustic mirror; and in a third form the regulator is carried by a sounding-board. The sonorous properties of the case may also be improved by the use of sounding-posts.

In fact, there are many details of construction which I need not take up your time in describing. The pressure between the electrodes can be regulated by means of magnetism, as well as gravity or the tension of a spring, especially when, as in this case, the metal employed is iron. The pole of a permanent magnet presented to the gauzes will hold them together with a force depending on the nearness of the pole. When an electro-magnet, E, is used as in Fig. 2, the current itself may traverse the coil of the magnet, and hold the gauze *g* against *g'* with a force which will be stronger when the current is stronger, and thus enhance the pressure of the sound-waves, so as to give a more decisive action. For since increased pressure of the sound gives increased current through the regulator and electro-magnet, the latter will react on the gauze so as to intensify the pressure and accentuate the voice. The electro-magnet E may be the core of the induction coil used with the transmitter.

In his original paper on the microphone, Professor Hughes states that the microphonic contact between two pieces of metal should be clean, but we find that the gauze may be either clean or tarnished, provided the rust upon it is not so thick as to make the surfaces adhere to each other.

Two pieces of gauze are not essential to the transmission of sounds, as one piece resting on a flat metal plate, either plain or corrugated, will answer; so also will two thin metal plates with roughened surfaces. But gauze is the most convenient and successful material we have yet tried. Its sensitiveness to tremors is remarkable, and it possesses an elasticity, when properly adjusted, which a continuous diaphragm does not seem to have. The numerous points of contact which it offers to the current, its low internal resistance, its lightness, portability, and cheapness, are all in its favour as a telephone transmitter.

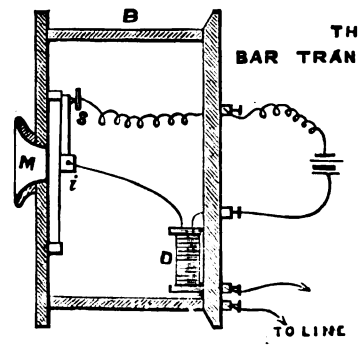

Fig. 3.

Fig. 4.

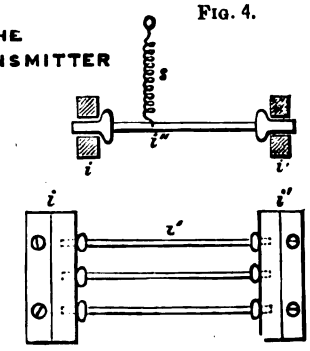

Fig. 5.

Another type of metal transmitters is shown in Figs. 3, 4, and 5. The B is the case, as before, with a match-board screen, M, and behind it a flat sounding-board carrying a metal microphone, *i*, with its adjusting spring, S. An induction coil, D, having its "primary" in circuit with the microphone and battery, and its secondary in circuit with the line, is also contained in the case. The microphone is formed of a light metal bar, *i''*, resting by its ends in holes drilled in two metal blocks, *i i'*, Figs. 4 and 5. An adjusting screw, *s*, regulates the pressure between the bar and its bearings. The metal found most suitable is common cast-iron, which may either be clean or slightly tarnished.

On speaking into the mouthpiece the vibration of the sounding-board causes the iron contacts to transmit the voice. A little clock oil applied to the bearings serves to remove the "boiling" or "buzzing" sound which is apt to spoil the action of the transmitter. Clock oil is chosen because it does not freeze in winter, and because it will preserve the iron from further rusting; but other liquids are found to answer the same purpose.

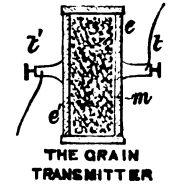

Fig. 6

The sound given by the cast-iron is loud, clear, and buoyant, but the proper adjustment of this form of transmitter is not so easy and abiding as that of the gauze type above described.

A third type of transmitter is shown in Fig. 6. In this the current-regulator consists of metal granules, *m*, enclosed in a box between two metal plate electrodes, *e e'*, connected to the terminals, *t t'*. The back of the box may either be of wood and the front of wire gauze, or both may be of sonorous wood. Iron or brass filings and turnings serve as metal grains, especially those with a good deal of inherent resilience, or spring; but a pile of small ¼in. screw nails, or a grit of "spongy iron," give better results. Spongy iron, having a rough surface, approximates to carbon in its action. To reduce the boiling or buzzing sound caused by the continual trembling of the particles, we sometimes immerse them in a

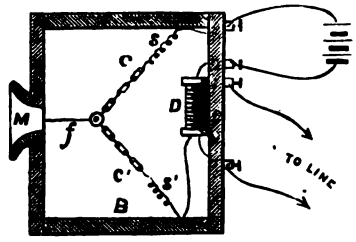
Digitized by Google

liquid, such as alcohol or thin oil. The liquid must not be viscous, else the vibration of the particles is clogged, and articulation ceases. Castor oil, for example, or glycerine, reduces the transmitter to silence. The removal of the buzzing in this way always appears to be at the expense of loudness in the articulate sounds. The steadying effect of the liquid on the delicate microphonic contacts is not its only influence, for, besides acting as a fine vibrator, it preserves the contacts from fouling overmuch, or from sticking together in the way investigated by Mr. Stroh.*

I may add that I have found some kinds of writing ink transmit speech when held in a box like that described.

A fourth type of transmitter is that shown in Fig. 7, where B is a box, as before, with a mouthpiece, M, and an induction coil, D. The mouthpiece in this case is closed by a tympan connected at its centre to a metal chain, or strip of chain mail, *c c'*, which is strained by the springs, *s s'*, and the tie *f*. This chain is the current regulator, and is traversed by the current. Between every two links there is a microphonic joint. The vibration of the tympan, on speaking in front of it, tightens or slackens the chain, thereby operating the current regulator and transmitting the sounds. The pressure between the links, which, by preference, are of iron, is regulated by adjusting screws.

Apart from their value as practical instruments, whatever that may turn out to be, these transmitters are instructive in a scientific sense. They show that metal contacts are quite capable of transmitting speech, and that, contrary to the doctrines of more than one eminent scientist, carbon has no monopoly of articulation. There has been a tendency of late to minimise the great discovery of Professor Hughes, and regard the microphone as a mere variety of the Edison carbon transmitter. Sir William Thomson himself appears



THE CHAIN TRANSMITTER.
FIG. 7.

to share this view, for he has stated, under examination, that he does not think the discovery of the microphone was any important advance beyond the carbon telephone. The part played by metals in the microphone, a part undreamt of until Professor Hughes's discovery, has been hitherto ignored. In point of fact, however, it is more than half of Professor Hughes's discovery, as these metal transmitters demonstrate. For the carbon microphone is now shown to be only *one* illustration of Professor Hughes's wide discovery, that a delicate contact between any two *conductors* has the property of transmitting sounds. The Reis original transmitter, with a delicate platinum joint, is seen to have been another illustration of the same phenomenon. Professor Silvanus Thompson has recently presented proof that Reis did send articulate words by his transmitter; and I believe there is no doubt he did. I have myself heard by telephone, and understood, single words spoken direct to the platinum contact of a Reis transmitter. Reis, then, employed a platinum microphone, without knowing it, as early as 1861; and Edison used a carbon microphone, without knowing it, in 1877. The discovery of Professor Hughes, in 1878, threw a flood of light on both inventions.

The action of tarnish was probably not observed before the experiments of Mr. Warwick and myself, as both Professor Hughes and Herr Reis were careful to have clean contacts. Even Mr. Edison, in the long catalogue of materials claimed for his transmitter, and numbering nearly all known substances, as well as several which remain to be discovered (either in this world or the next), does not, I believe, mention rust.

Mr. Munro here invited the attention of the meeting to some working specimens of the above-described transmitters. Proceeding, he said:—

My first intention was only to bring the metal microphone transmitters to your notice this evening; but perhaps something might be said in addition to the current theories of the action of the microphone from the point of view of these transmitters.

The original theory of Edison, that it is due to a reduction of the internal resistance of carbon by pressure, is probably not maintained any longer in face of the numerous experiments showing that there is exceedingly little reduction, if any. Then there is a theory—supported, I believe, by Sir William Thomson—that the action is due to an increase or diminution in the area of surface-contact produced by increase or diminution of pressure; but how the area of contact is to vary in simple ratio to the surface-pressure is a puzzle in this theory which is difficult to see through. A third theory, due, I believe, to Mr. Preece, is that the microphone acts by heating at the points of contact when the current passes. I have not seen this theory developed anywhere, and may not understand how the heating is supposed to act; but if it acts by altering the resistance of the points, then in the case of carbon we have a dimunition of resistance, and in the case of metals, more especially iron, a rise. Yet, as we have seen, metal points, as well as carbon ones, act as transmitters. The theory, then, does not seem to fit both classes of instruments. Again, it does not seem probable that the variations of temperature can be so quick and sudden as the transmission of sonorous currents requires. The logograph curve shows that a jerky action is necessary, and the heating and cooling of a body must be more or less gradual. Another reading of the theory may be that the heated points are of a spongy nature, and more sensitive to pressure; but here again it is difficult to see how the effect can be in simple ratio to the pressure. A fourth theory, supported by Professor Hughes and Professor Blyth, and probably first intimated by Mr. F. H. Varley,* attributes the action of the microphone to a small arc formed between the points, and this appears to me a likelier hypothesis. But I would propose a modification of it, and, instead of an "arc," in the ordinary sense, consider the cause a "silent" discharge through the film or stratum of air or liquid between the points, after the manner of lightning guard. With a strong current one can see sparks passing between the points of the microphone, but this momentary arc is due to excess rather than to normal action. The normal action is evidently produced by a silent discharge going on between numerous tiny projections on the carbon points, which in this respect resemble the corrugations or spines in two well-known forms of plate lightning arrestors used in telegraphy. We have to figure to ourselves the microphone points covered with irregular projections which touch each other, but are bathed in the surrounding air and ether. These projections, like the points of a lightning arrestor, are constantly discharging little jets of current from one to the other across the air between. But the action of the sound-waves is to move them to and from each other, thereby increasing and lessening the width of the air stratum, and varying the strength of the discharge. When this vibration is clogged by a viscous liquid, the sounds are muffled and indistinct.

The "boiling" or "buzzing" of a metal transmitter not properly adjusted reveals this "silent" discharge from a multitude of points. The ear hears in the telephone a peculiar soft noise, quite indescribable, but apparently made up of a million feeble ticks, the feeblest the ear can appreciate. Each tick seems to be caused by an infinitesimal discharge between two little points, and the agitation of these points causing the discharge is the perpetual tremor going on in all substances, especially elastic metals. A slight pressure applied to the microphone quiets this discharge and leaves the sonorous vibrations to act by themselves in disturbing the flow of electricity through the air. It silences the buzzing of the crowd, as I may call it, and allows the voice of the speaker to be heard.

With two pieces of iron wire gauze, one delicately resting on the other, I have sometimes obtained this breathing

* See *Journal of the Society of Telegraph Engineers*, Vol. IX., p. 182.

* See *Telegraph Journal*, Vol. VI., p. 404.

Digitized by Google

sound very perfectly without the application of heat. In loudness it resembled the rushing of a strong wind. The slightest oscillation of the upper gauze until it came to rest was rendered in the telephone. Even the periodic tremors of my hand, in contact with the table, were distinctly given, and broke up the blast like the puffing of an engine.

The application of heat, by the spirit flame, to two pieces of wire gauze in contact, increases the microphonic action between them in a similar manner, as can be shown by placing the spirit lamp below such a contact. When the flame is applied to the metal so as to heat the contact, the tapping of my hand, as heard in the telephone, becomes louder, and gradually dies off when the flame is removed. Hot metals and flame are known to discharge electricity better than cold metals, and hence, in all probability, the slow discharge of the microphone is accelerated by this means.

Heating the contacts can of course be applied to the metal transmitters which I have shown, especially the gauze forms; but I have not yet had time to properly try this plan. The superiority of iron in these transmitters may be due to the ease with which it discharges, as compared with the other metals tried; but heating facilitates the discharge of other metals besides iron. A transmitter of platinum wire gauze, which would not oxidise in the flame, as does copper, for example, might therefore be constructed; the spirit lamp being fed from a reservoir attached to the case and lighted at will by an electric current sent through a platinum wire on touching a press-button, or in the act of unhooking the telephone receivers from the case in order to converse.

When the microphonic contact is formed by two different metals, the application of heat generates its own current by thermo-electric action. I have here a contact formed of iron and German silver, and on applying the spirit lamp, and tapping, we hear the taps in the telephone. In Dr. Mathiessen's scale of thermo-electric effects, bismuth ranks 25, German silver 5·2, and iron 5. I have not yet made a thermo-electric microphoone to speak well, partly because iron and German silver do not give a very loud effect, and bismuth is difficult to get in a workable shape; but I hope soon to try the effect of bismuth gauze resting upon iron gauze, and artificially heated.

The recent experiments of Mr. Shelford Bidwell, communicated to the Royal Society on January 18th, 1883, appear to me to bear out the theory that the microphone acts mainly through the air discharge between the points. Thus he finds that the resistance of the contacts varies greatly with the strength of current when the pressure is small, and very slightly when it is great—that is to say, when the film of air is squeezed out. On reducing the pressure (with carbon at least), the resistance of the contact increases. Again, the resistance of the contact diminishes with increased current, an effect also noticed in the voltaic arc. Further, Mr. Bidwell finds that "when the strength of current exceeds a certain limit the resistance is greatly and permanently increased; the greater the pressure the higher will be such limit." This unexpected effect is difficult to explain on any theory but that of the "air discharge." May it not be due to a counter-electromotive force generated by the discharge? M. Edlund finds that a resistance is set up at the electrodes by a discharge in rarefied air, and the effect observed by Mr. Bidwell may be a similar one.

In his paper to the Royal Society Mr. Bidwell gives reasons for the superiority of carbon over metals in the microphone.

He says:—"The mere fact that a current causes delicately-adjusted metal contacts to adhere to each other is sufficient to account for the superior efficiency of carbon. A metal microphone might indeed be used to transmit the pitch of a sound, provided that its vibrations were sufficiently powerful to cause actual separation of the points of contact. The fundamental tone might in this way be conveyed, but it is clear that the minute superimposed vibrations due to the upper partials, upon which depends the distinctive character of a particular sound, would be very imperfectly represented, if not entirely lost."

I can only say that I have not found the adhesion of contacts in these metal transmitters troublesome, although iron, according to Mr. Stroh's* experiments, has a very high adhesive power. If the battery power is not too great, and the pressure on the contact is not excessive, there will be no sticking of the points.

On the question whether a metal microphone can convey the human voice, I will leave the transmitters to speak for themselves; but I may say that shrill or high-pitched voices, like those of women and children, seem to come out best. This appears to be due to the fact that the discharging distance in the case of metals is very small, and the contacts should not swing too far apart. In a female voice there are twice the number of vibrations per second as compared with the male voice, and the metal points must vibrate in very close proximity when a woman speaks to the instrument. The same peculiarity is, I believe, observed with carbon microphones, and any advantage carbon may have in this respect will lie, I think, in the greater width of arc or discharging distance which it can sustain by reason of the cloud of carbon particles carried by the current between the contacts. I may add that the conducting fumes in the heated metal microphones evidently enable these to sustain a longer arc than if they were cool.

So marked is this difference between male and female voices, that on some of the forms of transmitter I have shown it is possible to hear a female voice with singular clearness when a male voice cannot be understood without altering the adjustment. But, of course, a transmitter purely for female voices would not be very practicable, at least in our day. It would, indeed, be possible to have two transmitters, one for male and the other for female voices, connected at each end of the telephone line, so that a man might speak into one, and a woman into the other. But there would still remain the insurmountable difficulty of providing for the anomalous case of a youth whose voice was in the act of breaking. It would be too much, gentlemen, to ask him to fly from one instrument to another when his voice took a turn in one direction or the other, even if he knew when the anomaly was coming on. Fortunately, however, the gauze transmitter is available for all kinds of voices when properly adjusted; and the same may also be said for the other forms. For male voices more pressure is required on the contacts; but when once an instrument is adjusted for a middle voice, it will convey others of a higher and lower pitch. Thus a transmitter set to an alto voice will also serve for bass and treble speakers.

MR. STROH ON THE ACTION OF THE MICROPHONE.

An experiment, which may help to throw light upon the action of the microphone, was described by Mr. Stroh during a discussion on the theory of the microphone which followed the reading of Mr. Munro's paper at the Society of Telegraph Engineers and Electricians on the 8th inst.

Fig. 1. represents a very small and delicate form of Professor Hughes's so-called hammer and anvil microphone.

On a thin board, A, is fixed a little block, B, which serves to hold four brass uprights, C C′ and D D′.

A light spindle E, provided with a pivot or knife-edge at each end, rests on the uprights C and C′. Attached to the spindle E on one side is an exceedingly light concave reflector, F, while on the other side, and in good electrical contact with this spindle, is a thin rod of carbon, G. The latter rests at right angles on another rod of carbon, H, which is firmly fixed in the two brass uprights D and D′.

Terminals I and I′ communicate each with a pair of the brass uprights. A little spiral spring, the tension of which can be regulated by a small thumbscrew, serves to keep the two carbons in microphonic contact.

A loud ticking watch or other source of sound is placed on the board A.

The general arrangement of the experiment is shown in Fig. 2. M is the microphone just described. A lime-light, L,

* Some further investigation by Mr. Stroh on the subject of the action of the microphone will be found described below.

Digitized by Google

is placed behind a little screen with a small round hole in it, across which is stretched a fine wire, so that the image of the latter is thrown by the reflector of the microphone on a wall or screen at S, where a graduated scale may be fixed, and where by means of the image of the fine wire any deflection can be easily read.

A downward movement of the reflected spot of light on the screen S indicates a separation of the carbons at the point of contact, while an upward movement would be due to an approach of the carbons towards each other.

A telephone, T, a make-and-break key, K, a battery, B, and the microphone M are joined in circuit. The adjustment of the latter is now made, so that the ticking of the watch is heard as loud as possible in the telephone T, while the observer has one hand on the key K, and is also watching the spot of light at S.

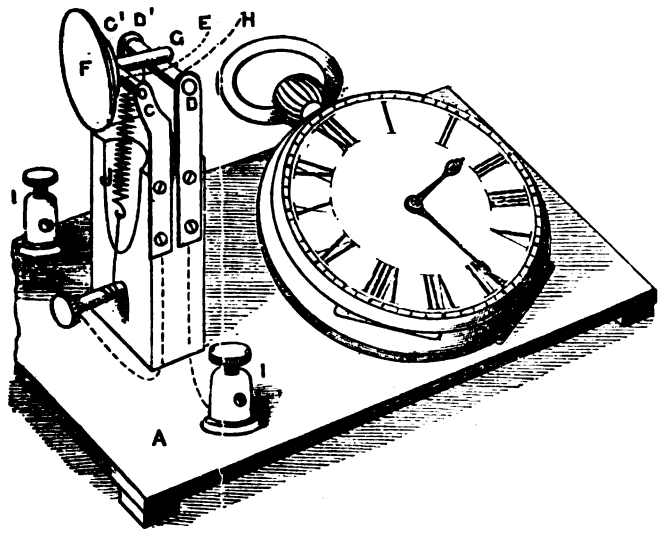


Fig. 1.

At the instant when the current is broken at K the spot of light moves upwards, not sluggishly, but suddenly and sharply, the sound in the telephone of course ceasing at the same moment.

On making contact again the spot of light, quite as suddenly, returns to its former position, while the ticking is heard again.

The distance through which the spot of light moves is very small, but the action is so decided and unfailing that there is no difficulty in observing it.

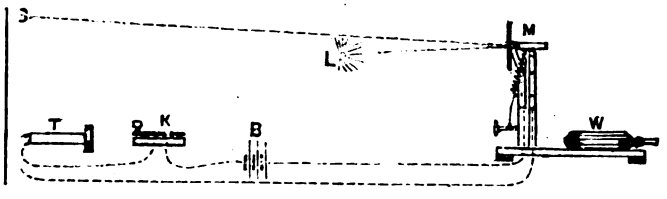

Fig. 2.

It happens sometimes that microphones are uncertain in their action, and will suddenly fail to work, and in observing the spot of light during some such failures it was found that it jumped upwards at the moment when the telephone became silent, and returned as soon as the microphone was brought into action again by a tap on the table.

It was *only* during the clear working of the telephone that the spot of light remained steadily deflected downwards, which seems to indicate that during the time when the carbons are really in what is called microphonic contact they are not in contact at all, or at all events that there is a repellant action at the points of contact.

With a single element of a small bichromate battery in the circuit the deflection was hardly perceptible; but with three elements the spot of light moved through one millimetre between making and breaking.

When a greater number of elements was used the deflection was also greater, but there was much hissing, and the spot of light was not steady.

With three elements the experiment succeeded best; with this number the ticking of the watch could be heard loudly and clearly without any hissing.

In order to arrive at an estimate of the distance which appeared to exist between the two carbons at the point of contact during their action as a microphone, it may be mentioned that the distance between the screen S and the reflector was six metres, and that between the fulcrum and point of contact of the microphone six millimetres, so that the former distance was 1,000 times greater than the length of lever in the microphone. This figure has to be doubled on account of a reflected beam of light moving through double the angle of the reflector itself.

The total deflection on the screen S being one millimetre, the distance to which the upper carbon was repelled during microphonic action under the circumstances described was therefore $\frac{1}{2000}$th part of a millimetre.

ELECTRIC LIGHTING AND LOCOMOTION.*

In my last lecture, I explained why small current combined with great electric pressure or high potential must necessarily be used for economy in electric transmission of power, and why, therefore, the series working of lamps and motors was better than the parallel system. I went pretty fully into the consideration of what was necessary to obtain safety, and we found experimentally that two conditions were essential: the first, that both the going and the return wires should be well insulated from one another as well as from the earth; the second, that the current should be absolutely constant in its strength, and not merely have the mean constancy obtainable with many of the so-called constant current dynamos.

The very important problem of supplying constant electric pressure to the mains, however many lamps or motors were being fed by them in parallel, was next considered, as well as the problem of supplying constant current to motors or lamps in series, however many lamps or motors were being worked in one circuit.

We ended by considering the great importance of driving quick moving tools like drills, fans, circular saws, &c., *directly* with electro-motors without intermediate gearing, because with such arrangement we saved first the loss of power that occurs in the shafting of a factory; secondly, the loss of power at the intermediate gearing employed to make the drill, or other quick moving tool, revolve much more rapidly than the shaft, and, lastly, we secured the great convenience of being able to bring the machine-driven tool to the work, instead of, as at present, the work to the tool. And there is one case where the driving of fans by electro-motors appears to me to be at the present moment of vital importance to us as citizens of London, I might almost say of national importance to us as Englishmen. For years past we have gone on breathing the foul air in the underground railway. Much grumbling has been the result, but hitherto no ventilation, and at the present moment we are contemplating, as a sort of final resource, the possibility of unsightly openings being made in the roadway of the Embankment to let out the obnoxious gases. Now why, I ask, do we not put fans at suitable intervals along the tunnel attached to quite small pipes for extracting the bad air? The fans could not, of course, be driven by steam-engines (there are steam engines enough in the tunnel already), nor could they easily be driven by shafting or belting, but an electro-motor attached *directly* to each fan would furnish the driving power without introducing any inconvenience whatever. No gearing would be necessary, a single insulated going and return wire would convey from motor to motor the electric power produced by a large dynamo outside the tunnel, and a steam engine might puff away in some back yard, out of everybody's way, and give us perfect ventilation on the underground railway.

And when on the subject of electro-motors, I explained that Professor Perry and myself had been led to construct electro-motors on a different principle from that usually adopted. In a dynamo machine there are two electro-magnets, and the machine acts as a producer of electricity because the work that is necessary to be done to move one of the magnets relatively to the other to overcome their attractions and repulsions is turned into

* Lecture II., delivered by Professor Ayrton, F.R.S., at the London Institution, March 15, 1883.

Digitized by Google

electric energy. In practice one of these electro-magnets is usually kept at rest, while the other is in motion. In one of them the current always flows in the same direction, while in the latter it is constantly being reversed in direction. The former is called the "field" or inducing magnet, while the latter is the "armature." Now, it can be shown that in every dynamo-machine the magnetism produced by the current flowing round the armature must necessarily weaken the magnetism produced by the current flowing round the field-magnets, and hence must necessarily diminish the power of the dynamo.

Hence the best dynamos have been so designed that while the exciting electro-magnets form a very strong magnet the armature only produces a very weak one. This result has been arrived at partly by making the armature of a dynamo small, compared with the field electro-magnets, and partly by giving it a squat form; and because the field-magnet is large, it is, as a rule, kept stationary, while the armature revolves inside its poles.

I went on to explain to you that Professor Perry and myself had concluded from certain theoretical and practical considerations, that in an electro-motor, on the contrary, the strengths of the two magnetic fields produced respectively by the field-magnet and by the armature should be equal, since the one, so far from weakening the other, can be made to strengthen the other, and since the armature from its shape is necessarily rather a weak magnet, whereas the field, or exciting magnet, from its shape is a strong one, that we had reversed the usual condition of things, and made the armature large and the field-magnet small, and that from this we had been led to make the armature stationary and surrounding the field-magnet, instead of, as is usual, the field-magnet surrounding the armature.

Our small field-magnet, then, carries the brushes and revolves inside the stationary armature, the coils of which are joined to the stationary commutator, which, unlike ordinary commutators, we make flat to save both space and expense.

Wherever the brushes happen to be at any particular moment, there two opposite magnetic poles are produced on the armature. As the brushes run round and round so do these poles, and the brushes, which, be it remembered, are carried by the field magnet, are so set that the magnetic poles in the armature are always a little way in front of those in the field-magnet. The latter, therefore, are perpetually running after the former, but never catching them.

The law connecting the power of electro-motors with their size I dwelt on, and I explained that if the length, breadth and height of a motor be doubled, so that its weight and cost becomes eight times as great as before, its power is about 20 times as great as before, and its efficiency or the ratio of useful power given out to electric power put in is also much increased.

I ended my lecture by referring, but from want of time only very briefly, to the governing of motors. An ordinary ungoverned motor goes very much faster when running empty than when there is a load on, but in practice it would never do for a piece of wood or iron in a lathe to rush round when the chisel was taken off, since not only would there be a great waste of power, but on next applying the chisel it would be probably broken by the wood or iron when rotating with such an excessive velocity. Not only, then, must we arrange in the way I described, that the supply of electric power is proportional to the demand, but also that the motors consume this power in proportion to the work they have to do; in other words, the electro-motor must be governed so as always to run at the same speed, whatever amount of work it may happen to be doing. I referred to the oldest form of governor for motors, which I have called the "spasmodic governor,"* and which I will now show in action. [Experiment shown and full explanation given.] The great objection to it is that it either supplies full power when the motor is running too slowly, or no power when it is running too quickly, and, therefore, cannot produce a constant speed. Our "periodic governor," which never supplies full power or no power, but always an amount of power exactly in proportion to the demand, I very briefly referred to, and which I will now describe to you more in detail [Ayrton and Perry's "periodic governor" shown in action and fully explained]; and, lastly, I referred to the most advanced system of governing motors, which we had arrived at by winding the motor with two distinct circuits in such a way that the current passing through one of them magnetises the iron, causes the machine to act as a motor, and, consequently, is itself resisted, whereas the current passing through the other circuit tends to demagnetise the iron and stop the motion, and, consequently, is itself helped on; in fact, we have combined a motor and a dynamo in one machine, and so have dispensed altogether with anything of the nature of a mechanical governor. In the spasmodic, as well as in our periodic governor; the regulating action is produced by the supply of power being cut off when the motor is beginning to go too fast, but in our combined motor it is usefully employed to reproduce electric energy, which is added to the supply in the main circuit. In the one case, when less work has to be done by the motor, less electric power is given it, while with our combined motor the supply always remains the same, but when much work has to be done by the motor, nearly all the electric supply is turned into useful mechanical work; whereas, on the other hand, when little mechanical has to be done, a portion of the supply, after being turned into mechanical work, is re-converted into electric energy, and added to the supply going to other motors. The difference in principle is of this nature—the periodic governor corresponds with a man who, when he has not much work to do, does not eat much, lives economically; in fact, whereas our combined motor corresponds with a man who always eats the same amount every day, but when he has little work to do on his own account, immediately goes and helps somebody else who is hard pressed with work. [Experiments were then shown with the combined motor, and it was proved that the change of load which diminished the speed of the ungoverned motor from 1,560 revolutions per minute to 508, only reduced the speed in one of Ayrton and Perry's governed motors from 1,250 to 1,184 revolutions per minute.]

But we find that it is not even necessary to wind the motor with two distinct circuits in order to obtain a certain amount of governing, and this arises from the fact that our machine will act as a motor without any winding at all on the revolving field-magnets. Here is an example of such an unwound motor. I pass a current through it, and it at once commences to revolve, and, as you see, revolves rapidly. [Experiment shown.] This arises from the fact that the magnetism in the stationary armature induces magnetism in the iron of the field-magnets, and the brushes are so placed that the magnetic poles in the armature are always just in front of those in the iron, which latter are always running round and round after those in the former, but never catch them up.

In some of the early electro-motors pieces of soft iron moved in the neighbourhood of stationary electro-magnets, but in that case the continuous motion of the iron was maintained in a totally different way from that employed in our unwound motors, because in those older motors a piece of iron was pulled towards a stationary electro-magnet, opposite which it would have stopped, but that just as it was approaching the end of the electro-magnet the current was stopped and the iron went on by its own momentum; the pulls were therefore intermittent and not continuous, as in the case of our unwound motor.

(TO BE CONTINUED).

* See *The Electrician* for March 10.

ELECTRICITY ON TRAMWAYS.

The success which has attended the electrical tramways at Berlin, Brussels, Dusseldorf, &c., worked on the Siemens plan, by a stationary generator and a movable motor, has directed the attention of tramway officials to the use of electricity. It is well known that horse-power is expensive, not to speak of its cruelty, and neither steam nor compressed air have as yet made good their claims to be used in this application. The experiments of Planté, Faure, Sellon, Volckmar, and others in the direction of storage have culminated in an attempt to use electricity in this way to tramway work. A series of successful experiments have been carried out on the Acton tram line, but a similar experiment which the public were invited to witness at Kew was not so successful. The principal reason arose, we understand, from the fact that there is a difference of ⅛in. in the gauges of these lines, and the axle of a car made to run on one line is not quite the same as an axle of a car made to run on another line. It is expected that in a few days a car will be running daily and continuously, and we shall then take the opportunity of illustrating the car, and describing the general and special arrangements. Meanwhile, it will not be out of place to give the views expressed at the luncheon on Saturday last at the Star and Garter Hotel, Kew Bridge. A large number of gentlemen interested in the work were present, the chairman, Sir D. Cooper, of the Electrical Power and Storage Company (the host of the day), presiding.

At the request of the chairman, General HUTCHINSON gave his experience at the earlier trials on the Acton Road. He stated that the car ran satisfactorily at the rate of about six miles an hour. The speed was thought to be good, as the car was carrying about five tons weight. It might be necessary to alter one or two details after the morning's experience, but it was not expected that the Board of Trade would make any difficulty in licensing the running of these cars.

Sir F. BRAMWELL proposed "The Success of Electricity,"

Digitized by Google

coupling the name of Dr. Siemens with the toast. Sir F. Bramwell pointed out that the applications of electricity were rapidly extending. It enabled us to talk and write at a distance. We were even able to grow vegetables by its use. Electricity had certainly developed wonderfully during the past few years. He knew of nothing that had made such great progress.

Dr. SIEMENS remarked that he had, probably, been connected with the applications of electricity longer than any other gentleman in the room. It was in 1843 that he first came into contact with Mr. Elkington, of Birmingham, and began to move in the domain of applied electricity. They had seen the telephone doing its wondrous work in carrying their voices to great distances, and they had now to witness the power of electricity in carrying them along in a tramcar. The electric railways with which he had been connected had run at the rate of twenty-five miles an hour. In Ireland one had lately been inspected by General Hutchinson, and was just about to be opened for traffic. The tramcar had to carry its own store of power. This would be charged into the car at convenient stations. Such a car would run upon common roads as well as on railroads. A much smoother movement was experienced in a tramcar propelled by electricity than that in an ordinary tramcar.

Mr. NOEL, M.P., in proposing "Success to the Electrical Power Storage Company," said:—Great as the advances in electricity have been, we have not yet discovered the means of effectively storing power when it has been generated. Once get the power of storage and it can be used in large or small quantities. He coupled with this toast the name of Mr. Sellon, one of the inventors, a gentleman with an intense love of science, and one who had devoted a great many years of his life not only to science generally, but to electrical science in particular; also the name of Mr. Volckmar as a co-operator.

Mr. SELLON, in reply, gave a detailed account of the work and estimated cost as applied to tramcars. After referring to difficulties encountered, and he hoped overcome, he went on to speak of the economy of electricity. In round figures it might be taken that, by the employment of electrical apparatus, an effective return of 50 per cent. was secured out of the steam horse-power taken from the stationary steam engine, and if the latter cost one halfpenny per hour the effective horse-power on the pulley of the working motor was obtained at as low a cost as one penny per hour. Assuming that each ton of weight of a tramcar with its load required one horse-power traction, an average force of five horse-power would be more than sufficient for a car and 40 passengers, and taking the working day of a car at 15 hours, the cost is shown at 75d. for 75 horse-power hours, or, in other words, 6s. 3d. per day for traction. The actual daily cost of horsing a tramcar was given by some of the metropolitan companies at 26s. The difference between the 6s. shown above as the cost of electrical power, and the 26s. paid for horses affords such a margin that, after abundantly providing for sinking fund, depreciation, repairs, contingencies, &c., a very great saving is effected. Another great public convenience was obtained in the means of lighting the car from the same accumulators used for the motive power. Where water or other natural power might be brought to bear there was no daily consumption of fuel, and the only outlay was really the sinking fund for depreciation of the machinery.

The following information has been supplied by the Electrical Power and Storage Company:—"This tramcar is fitted with an accumulator consisting of 50 Faure-Sellon-Volckmar cells, each measuring 13in. by 11in. by 7in., and weighing about 80lb. The accumulator is capable of working a tramcar with its full load for half a day, or in other words seven hours. When charged it contains about 560 ampere hours, of which 400 are withdrawn with the greatest regard to economy. The accumulators are stored under the seats of the car, and the current is communicated by insulated wire to a Siemens dynamo machine acting as a motor, and connected with the axle of the wheel. Therefore, as soon as the communication between the boxes and the dynamo machine is effected, the electric current being led into the dynamo motor sets the armature of the motor in revolution, and the power is conveyed to a pulley fastened on the same axle as the armature. The Siemens motor works most favourably with an electric motive force of 100 volts and a current of 60 amperes, equal to 6,000 volt-amperes or watts, and as 746 watts constitute an electrical horse-power, the result is a consumption of eight electrical horse-power, and a yield on the pulley of five and three-fifths electrical horse-power. The action of the motor may be reversed at will, and the power may be increased or diminished as required by adding to or taking from the number of cells composing the accumulator by means of a simple switch, and by breaking the circuit the motive power is stopped, and the break being then applied the car is almost immediately brought to a standstill. The cost of horse-power produced from a stationary steam engine of large size has been ascertained and is universally accepted as one halfpenny per horse-power hour. Five hundred steam horse-power would, therefore, cost 250 pence, equal to £1 0s. 10d. per hour. This power would be applied to the working of electro-dynamo or generating machines. One of the best-known inventors claims that he can supply a dynamo which will give an effective return of 95 to 97 per cent. of the power given to it. Without calling in question the accuracy of this pretension, it would be obviously unfair to adopt it as the basis of a calculation, and as there are many dynamo machines in the market which give a return of over 80 per cent., that is a more certain proportion to work upon. From 500 steam horse-power given to the dynamo, a return would therefore be obtained of 400 electrical horse-power. The dynamo would be worked to charge electrical accumulators, which in turn work an electric-dynamo motor machine from the fly-wheel of which the direct power is obtained. It is ascertained that when 25 per cent. of the maximum charge which the accumulators are constructed to receive is permitted to remain in them they attain their best working efficiency, and the 75 per cent. may be withdrawn at a loss of not more than 10 per cent. on the quantity so withdrawn. Of the 400 electrical horse-power given by the dynamo to the accumulator, the accumulator would give to the motor 360 electrical horse-power. The Siemens dynamo when used as a motor gives a return of 75 per cent. of the energy put into it, but taking only 70 per cent. the 360 electrical horse-power given by the accumulators to the motor will yield on the pulley of the dynamo 252 effective horse-power. In round figures, consequently, it may be taken that by the employment of electrical apparatus an effective return of 50 per cent. is secured out of the steam horse-power taken from the stationary steam engine, and if the latter cost one halfpenny per hour the effective horse-power on the pulley of the working motor is obtained at as low a cost as one penny per hour. Assuming that each ton of weight of a tramcar with its load requires one horse-power traction, an average force of five horse-power would be more than sufficient for a car and forty passengers, and taking the working day of a car at fifteen hours, the cost is shown as seventy-five pence for seventy-five horse-power hours, or, in other words, 6s. 3d. per day for traction. It must be borne in mind also that out of the fifteen hours there would be about three hours' stoppages, and that the electrical energy is only expended when the car is actually in motion. If the question be asked, "What are the relative initial or first costs of horses, steam, and electrical machinery for tramcars?" the answer is that they will be almost identical, but that the last named will have the advantages of requiring less space and a smaller number of assistants, combined with an immunity from those epidemics which at times incapacitate the stud of a tramway company. The actual daily cost of horsing a tramcar is given by some of the metropolitan companies at 26s. The difference between the 6s. shown above as the cost of electrical power and the 26s. paid for horses affords such a margin that after abundantly providing for sinking fund, depreciation, repairs, contingencies, &c., a very great saving is effected. Another great public convenience is obtained in the means of lighting the car from the same accumulators used for the motive power. Where water or other natural power may be brought to bear there is no daily consumption of fuel, and the only outlay is really the sinking fund for depreciation of the machinery."

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on Thursday at St. Michael's Hall, George-yard, Lombard-street, Sir Henry Drummond Wolff, M.P., in the chair.

Mr. R. M. CUNNINGHAM (the secretary) having read the notice convening the meeting,

The CHAIRMAN said—Now, gentlemen, I will detain you as short a time as I can in bringing before you the business of the meeting. In the first place I shall have to propose that a dividend be declared at the rate of 3 per cent., to which, I suppose, no opposition will be raised, and after that certain resolutions will be submitted to you by shareholders with regard to the division of the shares. Now, I shall merely wish to say one word with regard to that division. On a former occasion, at the request of shareholders—certain shareholders—these resolutions were submitted to you, and at that time great objection was raised to them by certain of the shareholders present, who brought forward arguments against this division. We had a very large number of proxies at that time in our possession, but in consequence of the opposition that was manifested by the meeting, the directors thought that they would not be justified in using those proxies until the shareholders had had the subject more fully put before them. Afterwards a certain number of shareholders, according to the statutes, holding a certain number of shares, requisitioned the Board to bring this question once more before a general meeting of shareholders, and I may say, without expressing any opinion one way or the other on this division, that the directors had no alternative, even had they wished to have one, in calling a meeting, and submitting these resolutions to you, and giving the opportunity to the shareholders who were in

Digitized by Google

favour of it to submit their views before their brother shareholders. We desired to put the question fairly before the proprietors, as, in our opinion it is entirely a question for the shareholders to decide. The duties of the Board are to manage the affairs of the Company, and not to propose to alter the shape in which the property is held; but these shareholders, holding, as you are informed, over 11,000 shares, have sent us a requisition, and we then determined to send the proxies out in such a form as would give every shareholder the opportunity of recording in which way he considered it right the decision should be come to. Well, without going into any question of statistics, I may say that the proxies that have been specially noted as in favour of the resolutions are about five times in number to those which are against them. I say the directors have exercised no influence to procure that result, but the shareholders have spontaneously sent their proxies in.

Mr. BURT: Do you mean five times the number of proxies or of votes?

The CHAIRMAN: Of votes. I merely inform you that to tell you that this is a question for you to decide, and we have no alternative but to use the proxies in the way the shareholders have directed us to do. I will now move that a dividend of 3 per cent. on the reduced capital of the Company, for the year ending 30th September, 1882, be, and the same is hereby declared payable on the 16th inst.

Major WOOD: I have much pleasure in seconding that.

The resolution was put and carried unanimously.

Mr. HERRING said that in the course of his life he had had many resolutions to propose, but he had never felt greater pleasure than he experienced on the present occasion. He believed that the division of the shares into preferred shares and deferred shares would put money into his pocket, and into the pockets of his fellow shareholders. Many arguments had been urged against the operation which it was now proposed to make, but he would only notice two; one was that the proposal was rather absurd, because the deferred shares would be only worth a few shillings, but he believed the result would show that they would be worth a good deal of money. Then it was contended that the conversion of the shares into the two different denominations would promote gambling on the Stock Exchange, but the Stock Exchange had to deal in other matters besides the shares of the Western and Brazilian Telegraph Company. He thought the shareholders ought to consider their own interests, and not whether the proposal would induce speculation or not. He even thought that if the deferred shares were bought by speculative men they would advance the interests of the Company, because what they wanted was energetic men. He thought the division of the shares as proposed could not possibly do any harm, but that on the contrary it would do good by introducing a further number of shareholders which would be the means of promoting the prosperity of the Company. In conclusion, he moved a series of printed resolutions having for their object the division of the shares into deferred and preferred shares.

Mr. WOOD seconded the resolutions.

Mr. BURT asked if there was any precedent for dividing shares so that one half, the deferred, should have a cumulative dividend.

Mr. BOMPAS (the solicitor) thought it was well known to all those who had had to deal with preferred and deferred shares, that it was usual for the deferred shares sometimes to have a cumulative dividend, and sometimes not. The advantage of a cumulative dividend was that there was no competition between the two classes of shareholders. With regard to their being any precedent for the proposal, the Great Northern B shares were cumulative.

Mr. BURT said that he was satisfied that the directors would find that instead of this measure uniting the shareholders it would cause dissention, and the result would be great difficulties to the board. He thought the directors themselves should have expressed some opinion on the subject. He believed the movement was made in the interest of speculators on the Stock Exchange, and that it would result in many questions of litigation. No doubt there would be disputes as to the amount applied to the reserve fund, because this property was running away every year in value, and arrangements would have to be made for replacing the cables. One man would want his dividend immediately, and another man would say that he would rather wait so that there would be two competing interests. He thought the matter would bring about great trouble to the directors.

A SHAREHOLDER asked whether the proposal was likely to interfere with the negotiations with the Brazilian Government.

The CHAIRMAN replied that the negotiations were at present in abeyance. In reply to Mr. Burt, he wished to say that the directors did not wish to put themselves in the position of having to defend or attack the present proposal. They considered in January that they were more than justified in submitting the resolutions to the general meeting from the very influential and powerful representations that had been made to the Board, and which were so numerous and so repeated that they would not have been doing their duty if they had not submitted the resolutions to the shareholders. With regard to the requisition, he did not think that they had anything to do with the profession of those who had signed it.

Mr. MORRISON pointed out that it was quite optional to any shareholder to convert his shares or not, and, therefore, as he could retain his shares, if he chose to do so, in their present shape, he could not possibly be hurt by the present proposal.

The CHAIRMAN, in reply to a question, said that whenever a proposition came from the Brazilian Government for the purchase of the line, it would be submitted to the shareholders.

Mr. HERRING having further advocated the proposal,

The resolutions were put to the meeting and carried, 14 voting for and 7 against them.

A poll was demanded, the result of which was 2,214 votes for the resolutions, and 4,322 against them.

The proceedings then terminated in the usual manner.

THE GERMAN UNION TELEGRAPH AND TRUST COMPANY (LIMITED).

The twelfth ordinary general meeting of shareholders of the German Union Telegraph and Trust Company (Limited), will be held at the offices of the Company, 66, Old Broad-street, London, on Wednesday, the 21st inst., at 12 noon, when the following report of the directors will be presented:—

The directors beg to submit the accounts and balance-sheet for the twelve months ending 31st December, 1882, including in the accounts the coupon in respect of that date just received from the German Union Company of Berlin. The total receipts during the twelve months amount to £11,427 12s. 3d., which, with a balance of £11 0s. 4d. brought forward from last account, make a total of £11,438 12s. 7d. The working expenses for the same period amount to £787 12s. 9d., leaving a balance of £10,650 19s. 10d. Out of this amount an interim dividend of 5s. 9d. per share was distributed on the 21st January last, and the directors recommend the payment of a further dividend of 4s. 10d. per share, making a total distribution for the year of 10s. 7d. per share, free of income tax, or at the rate of £5 5s. 10d. per centum per annum, leaving a balance of £41 4s. to be carried over to the next account. The reduction in the dividend now payable arises from the interruption of the Lowestoft-Emden cable from January to the middle of March, 1882, and to the increased working expenses consequent upon the establishment of the Emden-Valentia line. Since that line was opened the traffic has shown a satisfactory increase. The Lowestoft-Emden cable has worked well since its repair, and the Emden-Valentia cable is also in good working condition. The cable house at Lowestoft was washed away by a gale on the 5th inst., but temporary arrangements have been made by which the communication is maintained. A new cable house will be built forthwith. The preference capital issued by the German Union Telegraph Company of Berlin was fully subscribed, and the first year's interest coupon paid by this Company as their London agents in January last. According to the Articles of Association, Sir James Anderson, one of the directors of the Company, retires by rotation, and, being eligible, offers himself for re-election. The auditor, Mr. Henry Dever, also retires, but offers himself for re election.

ELECTRICAL POWER STORAGE COMPANY.—According to the report of the directors the principal work has been hitherto the sale of the company's patent rights to other companies abroad and the promotion of inventions, but it has likewise done a good deal in the way of demonstrating the practicability of the efficiency of the accumulators. The profit and loss account shows a balance of cash and shares of £346,930, but the most part of this is shares and royalties payable by instalments, so that no distribution is to be made at present. The directors, however, recommend that the preliminary expenditure of £16,819 should be written off at once. Altogether, it has paid £516,907 in shares and cash for the patents it holds.

SLIP

THE BLACK SEA CABLE.—The cable between Odessa and Constantinople is now restored.

THE SPERRY ELECTRIC LIGHT COMPANY.—This recently-formed company is reported to be establishing large works in Chicago.

EXPORTS.—The value of telegraphic wires and apparatus exported from this country during last February amounted to £22,738.

PROVISIONAL ORDERS.—The application for provisional orders under the Electric Lighting Act in respect of Northfield and Belfast have been withdrawn.

THE FYFE-MAIN ARC LAMP.—Twelve Fyfe-Main arc lamps of 3,000 actual candle-power have been selected to light the Houses of Parliament, Sydney, New South Wales.

UNDERGROUND WIRES IN NEW YORK.—The New York State Senate has passed to its third reading the Bill compelling all telegraph, telephone, and electric light wires to be put underground.

APPOINTMENT.—Mr. Alfred R. Bennett has resigned his post as engineer to Messrs. D. and G. Graham, of Glasgow, and has been appointed engineer for Scotland and Ireland to the National Telephone Company.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The directors of this company had an interview with Lord Derby, on the 20th instant, in order to obtain, if possible, some support in the shape of a subsidy.

THE AUSTRALIAN CABLES.—The Eastern Telegraph Company notifies the restoration of telegraphic communication with Australia. Further repairs to the cables are, however, still necessary, and these may cause another temporary interruption.

SCIENCE AND ART DEPARTMENT, SOUTH KENSINGTON.—The 1883 examinations of this department are announced to be held as follows:—Sound, Light, and Heat, on 8th May, from 7 to 10 p.m.; Magnetism and Electricity, 9th May, from 7 to 10 p.m.

THE POST OFFICE.—The Edison Company is about to extend the existing electric light arrangements by an additional 1,500 lamps for use at the Post Office. The current for these lamps will be supplied from the Central Station, at the Holborn-viaduct.

MACMAHON'S TELEGRAPHIC NEWS COMPANY.—It is notified that a general and final meeting of this company is to be held at 10, Old Jewry-chambers, E.C., on the 23rd April, at 2 p.m., to receive the liquidators' accounts showing how the winding up has been conducted.

PRIVATE TELEPHONIC COMMUNICATION.—It is stated that a contract has been entered into between the Postmaster-General and Mr. John Burns for special telephonic communication between Glasgow and Mr. Burns's residence, Castle Wemyss, Wemyss Bay, a distance of 31 miles.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending March 9, 1883, were £3,118, and for that ending March 16, £2,882, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE "CALABRIA."—The telegraph steamer "Calabria," belonging to the Telegraph Construction and Maintenance Company, which has been employed in transport work since the beginning of the Egyptian campaign, arrived at Portsmouth on Monday, having left Alexandria on the 6th inst.

THE UNITED TELEPHONE COMPANY.—This company give notice to their exchange subscribers that they have decided to take advantage of the Easter holidays by closing their exchanges on Saturday, the 24th inst., in order to enable the company to carry out extensions rendered necessary by the large increase of the business.

THE LAW COURTS CHAMBERS.—This huge pile of buildings, situate opposite the new Law Courts, at the entrance of Lincoln's Inn-fields, is to be lighted by Swan lamps. The electrical work is being carried out by Messrs. Crompton and Co., for the Swan Company. The same firm is also carrying out the general engineering work of the building.

WIRES IN CHICAGO.—All the wires of the Mutual Union Telegraph Company, in Chicago, were cut by order of the mayor on the 2nd inst., because the provision of the franchise which required the company to put its wires underground by March 1 had not been complied with. The wires of the Board of Trade Telegraph Company were also cut.

BOOKS RECEIVED.—"Die Galvanischen Batterein Accumulatoren und Thermosäulen," &c., von W. Ph. Haunck, and "Die Elecktrischen Beleuchtungs Anlagen," von Dr. Alfred von Urbanitzky, being Vols. IV. and XI. respectively of the "Electrotechnische Bibliotek," published by A. Hartleben, of Vienna, Buda Pesth, and Leipzig. Price, 3 marks each (about 3s.).

THE SAMARA SUGAR ESTATE.—Messrs. R. E. Crompton and Co. have received the order to light the works on this estate by means of the electric light. This work is but a small part of that being carried out by the firm in Russia. Quite recently apparatus has been sent there by them to light several mills in and around Moscow, supplying electric current for about 1,000 Swan incandescent lamps, and about 60 arc lamps.

SS. "TARAWERA."—The Edison lighting plant on board this steamer, belonging to the Union Steamship Company of New Zealand, is reported to have worked well on the voyage from Greenock to Melbourne. Only 10 lamps out of a total of 150 gave out during the voyage. As the loss of lamps during the first few weeks after the starting of an installation generally averages higher than that which occurs after the plant has been in use for a short period, owing to the weeding out of defective lamps, the result stated above may be reckoned as very satisfactory.

NEW COMPANIES.—The following companies have been recently incorporated, viz.:—The Edison Light Company of Milwaukee, with a capital stock of 200,000dols.; the Bernstein Electric Light Company of Eastern New Hampshire, with a capital of 100,000dols.; the Electrical Accumulator Company of New York, capital 50,000dols.; the Overland Telephone Company, New York, capital 1,000,000dols., with power to be increased to 10,000,000dols; and the Sun-light Company, New York, for lighting by electricity and transmission of electric power, capital 5,000,000dols.

ELECTRIC LIGHTING FOR VIENNA.—A Reuter's telegram from Vienna, dated Wednesday, March 21, says:—Negotiations are going on between the Brush Electric Light Company and the Vienna Town Council respecting the lighting of this city. The company offers at its own expense to lay cables in every part of Vienna in return for the exclusive privilege of supplying the electric light here for a period of fifty years, whether for public or private purposes. Public opinion, however, is against such an arrangement, and it appears unlikely that the company will succeed.

THE EDISON SYSTEM IN MOSCOW.—A correspondent writes from Moscow, under date March 10:—"We have

Digitized by Google

several installations of the Edison light here at Moscow, erected under the superintendence of Mr. J. J. Robins, the engineer and representative of the company. One large cotton mill is completely lighted with 320 of the A lamps, and other installations are in course of being carried out. This light proved also a complete success at a large ball lately, where forty B lamps gave a good light from six p.m. to seven in the morning without a flicker. The current was supplied from an Edison E dynamo."

PHOTOGRAPHY BY ELECTRIC LIGHT AT NIGHT.—During a fancy ball recently given at the Queen's Hotel, Eastbourne, Messrs. Lavers and Co. most successfully photographed 120 of the guests in their fancy costumes. The lighting of the studio and ball room was carried out by the Eastbourne Electric Light Company, under the direction of Mr. H. M. Sayers, the Company's electrician and manager. The whole installation was provided at a few hours' notice, and was removed before 10 a.m. the following morning. Mr. Sayers, who has been with the Eastbourne Company from its commencement, was warmly complimented on the success of his work.

UNITED TELEPHONE COMPANY v. HERDEN.—Our readers will remember that the defendant in this case was, as reported in our last week's Notes, committed to prison for contempt of court in disobeying an order restraining him from supplying certain telephonic instruments in infringement of the plaintiffs' patent. His counsel appeared before Mr. Justice Fry on the 15th instant, stating that the defendant humbly apologised for the contempt he had committed, and expressed his deep contrition.—Mr. Cozens Hardy, Q.C., on behalf of the plaintiffs, left the matter in the hands of the Court.—His lordship thought, under the circumstances, that the apology tendered was sufficient, and ordered the prisoner to be discharged.

THE LIGHTING OF LIGHTHOUSES.—In the House of Commons on Monday last Mr. Chamberlain, in answer to Mr. Dawson, said that the committee on lighthouse illuminants had already held some meetings and made considerable progress with its arrangements. It had been thought desirable to increase the scope of the inquiry, and he could not say exactly on what day the proposed experiments to test the relative powers of gas, oil, and electricity would take place, because that would depend on the weather and many other circumstances; but he had no reason to believe that any time would be lost. It is probable, we may add, that Professor Tyndall and Dr. Siemens will be members of the above-mentioned committee.

ELECTRIC LIGHTING FOR DUNDEE.—We have reason to believe that the town of Dundee has arranged with the Brush Company to light the streets. A 250 horse-power steam engine is to be put in hand as soon as a suitable permanent building can be prepared. The town allows four years for the execution of the lighting work. At present, as has been stated in *The Electrician*, there is a small Brush installation at work in Commercial-street. It is owing to the admirable way this has been managed that the larger order is now given. The installation consists only of a portable Robey engine and six-light dynamo (Brush) on one bed plate. The lamps are on posts in the centre of the street. On a recent visit we observed that the steadiness of the light was very great, a result due to Mr. Morton's care and supervision.

THE THERMO-ELECTRIC POSITION OF IRIDIUM.—At the eighth meeting of the Royal Society of Edinburgh held this week, Professor Tait gave an account of some experiments made by himself "On the Thermo-electric Positions of Pure Rhodium and Iridium." His purpose in following out these experiments was, he said, to discover two metals which should give lines on the thermo-electric diagram parallel to that of lead, or which, in other words, should have no Thomson effect, but which, at the same time, should be so far apart as not to be within the limits of experimental error; and so to be enabled to construct a thermo-electric thermometer. He had found that rhodium and iridium fulfilled the first condition, but that, unfortunately, their lines almost coincided. He meant to pursue his experiments with the metals allied to platinum in the hope of finding the desired result.

A NEW CABLE.—A correspondent sends us the following extract from the Portuguese *Official Gazette*:—"Mr. Jean André Braam has signed a contract with the Government for the laying and working of a submarine cable from Portugal to the Western Islands (Azores), and from thence to America, Great Britain, France, and Spain. He has deposited £800, which can be taken up on the commencement of regular working between Portugal and the Island of St. Miguel. The concession is for the space of twenty years, the cable to be in complete working order between Portugal and the Island of St. Miguel in the space of one year, from thence to one of the American States in eighteen months, between St. Miguel and Great Britain in three years, and between the island and France and Spain in four years. Tax per word between Portugal and the islands not to exceed half-a-franc. For telegrams between the Azores and England or France the rate to be authorised by Government."

THE BRUSH LIGHT IN THE CITY.—At a meeting of the Commissioners of Sewers, on Tuesday, Mr. Deputy Pepler presented a report from the Streets Committee, recommending that the contract with the Brush Electric Light Company be continued for another year on the present terms and conditions, except that power be reserved to the commission to terminate the arrangement at any time within that period by 90 days' notice. The report was agreed to, as was also another report by the same committee relative to Sugg's experimental gas lighting in Fleet-street, and Siemens's patent experimental gas lighting in Holborn, stating that, having regard to the increased cost, they are not prepared to advise the adoption of the systems, but recommending that the reports of the engineer be printed for the information of the commissioners. So it seems, after all, that increased light by means of gas is not to be had without paying the piper, and that to a tune so unaccustomed that the rulers of the City "are not prepared to advise the adoption of the systems."

LEGAL.—The case of "The Plating Company *v.* Farquharson and others (trading as The Nickel Plating Company)" came before the Lord Chancellor and Lords Watson and Fitzgerald on the 15th inst. This was an appeal from a decision of the Court of Appeal reversing a judgment of Vice-Chancellor Bacon, pronounced in an action brought by the appellants as plaintiffs against the respondents for the alleged infringement of certain letters patent relating to nickel plating. The appellants, who carry on business in Hatton-garden, are the owners of certain letters patent, known as Adams's patent, granted to William Brookes for the invention of improvements in the electro-deposition of nickel, communicated from abroad by Isaac Adams, jun., of Boston, in the United States. The respondents, who are also electro-platers, carry on business at Greek-street, Soho, and it was alleged that in the process of nickel-plating they had infringed the appellants' patent. The Court below decided that there had been no infringement of the appellants'

Digitized by Google

patent. Their lordships, without calling upon the respondents, dismissed the appeal, with costs.

Electric Lighting in America.—We take the following items of news from our New York contemporary, the *Sanitary Engineer*:—"The City Council of Dayton, O., adopted, Feb. 23, a resolution accepting the proposition of the Fuller Electric Light Company to light the city for one year.—The streets of Seabright, N.J., and the ocean boulevard are hereafter to be lighted by electricity at the expense of the wealthy cottagers and hotel people.—The Arnoux Electric Light Company has received an order to furnish light for the United States and Canadian departments at the Fisheries Exhibition to be held in London.—The telephones in the fire engine houses in Newark were burnt out Sunday night, by contact of the fire department wire with an electric light wire. The woodwork in the office of the superintendent of fire alarms was set fire to.—A recent conference was held in Boston between many prominent men of that city and the officers of the Edison Electric Light Company of this city, to consider the project of establishing an Edison plant in Boston like that in operation here.—The Thomson-Houston system of electric lights is being introduced into Utica, fifty-four lights having been subscribed for by merchants.

A Sulphate of Copper Battery.—A new form of battery devised by M. Callaud is now made by Messrs. Dumoulin and Froment, of Paris. It is made up as follows:—Sulphate of copper is placed in a glass jar, in the bottom of which are two holes. The positive pole is formed by a copper wire, rolled in the shape of a spiral at its lower end, and is without weld, solder, or any break in its continuity. A protection of rubber, sufficiently thick, formed by a simple tube slipped over the end of the copper wire, covers it from the bottom to outside the outer jar. The zinc is suspended by two hooks, which are passed through two holes made in the top of the jar, and rest on the edge of the outer jar. This battery, says *L'Electricien*, has one peculiarity which can be of a certain use as regards attending to it—namely, the difference generally noticed between the level of the liquid inside and outside of the glass jar. If the battery is in good condition, the liquid in the jar is lower than that with the zinc, thus showing that the solution of sulphate of copper is concentrated, or nearly so, and that of zinc sulphate is not so. This case proves the battery to be in good working condition. If, on the contrary, the heights of the liquids are equal, or even if the sulphate of copper should be higher than the other, it is because the copper solution is not concentrated enough, or that the sulphate of zinc solution is overcharged with salt. The constants of the battery thus made do not differ at all from those of the ordinary Callaud (E = about 1 volt, R = 6 to 8 ohms), because the positive pole is always kept in the solution of sulphate of copper, which escapes from the jar through the two holes.

Oxidation-products of Carbon obtained by Electrolysis.—An abstract of a paper by A. Millot in the *Bull. Soc. Chim.* appeared in a recent number of the *Journal of the Chemical Society*. According to the author gas carbon electrodes are much more rapidly attacked in alkaline solutions than in pure or acidulated water. The dark solution obtained by the electrolysis of a 5 per cent. solution of ammonia with gas-carbon electrodes becomes acid on evaporation. It contains ammonium nitrate and an acid which may be isolated by evaporating almost to dryness, heating the precipitated black matter with alcohol, and evaporating the alcoholic solution, when crystals of the ammonium salt of the acid, mixed with ammonium nitrate, separate out. The crystals are dissolved in water and mixed with lead nitrate which produces a crystalline precipitate. This precipitate is suspended in water, treated with hydrogen sulphide, the solution filtered from lead sulphide and evaporated, when the acid separates out in needles. Its composition will be determined when a sufficient quantity has been obtained. The black matter precipitated by the addition of an acid to the solution obtained by the electrolysis of a 2 per cent. solution of potassium hydroxide has the composition O 37·72; C, 58·65; H, 3·27; N, 0·56. The whole of the nitrogen was evidently not removed from the carbon electrodes, although the latter were treated with chlorine for 150 hours. The black substance is soluble in boiling water even after being dried at 100deg., but is precipitated by ebullition in contact with air. It is insoluble in alcohol, ether, benzene, and chloroform. When an aqueous solution of the black substance is treated with a current of air, it absorbs a considerable quantity of nitrogen, which, however, is again partially removed by continued passage of the air, the substance at the same time being oxidised and destroyed.

International Electric Exhibition at Vienna.—From information received from the head-quarters of this exhibition in Vienna it seems that it is likely to prove a good one. The following list of names of intending exhibitors that have been received will be interesting:—Italy will be represented by the Societa Anonima Generale Italiana dei Telefoni, of Naples, with a collection of lighting apparatus and telephones; Alessandro Lucchesini and Jules Lorenzelli, of Florence, with various telegraphic apparatus; Rialti Vincenzo, of Forli, with many novelties in incandescent lamps; Dr. Charles Labus, of Milan, with his laryngofâtome for demonstrating laryncoscopic operations; and Dr. Samuele Salaghi, of Rome, with electro-therapeutic apparatus. We may next mention France, which will be represented by the Maison Breguet and L. Sautter, Lemonnier, and Co., of Paris, both world-renowned firms. The former firm are known as one of the oldest makers of telegraph apparatus; now, however, to keep abreast with the times, they are manufacturing lamps, dynamo-machines, galvanoplastic apparatus, &c. The exhibits of L. Sautter, Lemonnier, and Co. will include a lighthouse; besides this, they have promised to send eight dynamo machines, ten large reflecting apparatus, and a great number of electric lamps. M. Lazare Weiller, of Angoulême, will show his wires, &c., of silicium phosphor bronze and copper; and Ch. Ferd de la Roche, of Paris, regulators and incandescent lamps. Switzerland will be represented by Emil Bürgin, of Basle, and the Swiss Edison Company. Herr Paul la Cour, of Askovhus, Denmark, the inventor of telegraph apparatus, and Wilhelm Helle, sen., of Copenhagen, inventor of telephones, have promised to exhibit. From Germany will come the firm of Keiser and Schmidt, of Berlin; the Rheinische Electricitäts-gesellschaft, of Mannheim; C. H. F. Müller, of Hamburg; and Heilmann-Ducommun and Steinlen, of Mühlhausen, whose exhibits at Paris will be well remembered. They will, amongst other things, show the application of electric power to ordinary workshop machinery. Dr. Emil Boettcher, of Leipsic, will show secondary batteries; Josef Zimber, of Furtwangen (Baden), electric clocks; Michael Sendlner, of Munich, electric thermometers; Greiner and Friedrichs, of Stützerbach, (Thuringen), incandescent lamps; Dr. Greitner, of Auerhammer, cables; E. M. Reiniger, of Erlangen, electro-surgical apparatus; Dr. Albert Lessing, of Nurnberg, various apparatus; Dr. Johann Wilckens, of Bremen, a Droste's type-printing telegraph; and Spiecker and Co., of Cologne, dynamo-electric machines.

AN ELECTRIC THERMOMETER.—M. Becquerel was engaged during the winter in experiments, the object of which was to ascertain whether snow had the effect of protecting the ground from frost. In carrying out these experiments he pressed electricity into his service in a most ingenious manner. Before describing his apparatus, we may, however, state that the result of his experiments was as follows:—That a covering of snow does not protect the soil and seed from freezing, but only hinders to a certain degree the too extensive radiation of heat from the soil, and is converted into water at 32deg., which sinks into the earth and somewhat raises its temperature. Also, that a heavy sod does more to protect the soil and raise its temperature than ever so thick a layer of snow. The experiments were carried out in the Jardin des Plantes, Paris, and in the following manner, according to our contemporary, the *Weiner Landwirthschaftliche Zeitung* for January last:—"Two covered wires of unlike metals—copper and iron—were soldered together at both ends, which were left uncovered for this purpose; otherwise they were covered their whole length, for the purpose of insulation, with gutta percha and silk. On the soldered ends of these double wires being exposed to different temperatures a current is generated in them, and the greater the difference in temperatures the stronger the current, but the current ceases when both are exposed to the same temperature. This electric current was caused to act on a magnetic needle suspended so as to move freely over a graduated circle, a kind of compass. The copper wire formed a vertical frame around the needle parallel to its normal direction. As long as both ends of the double wire are at the same temperature the needle continues to point to the north, being subject only to the earth's magnetism, but as soon as there is any variation in temperature the needle is sure to move instantly and take another position, which it will keep until some other change of temperature takes place. The application of this apparatus to the measurement of soil temperatures was made as follows:—One of the soldered joints was buried in the earth to a depth at which it was desired to take the temperature, and the other end was put in a water bath at any desired distance from the first. The temperature of the latter could be increased or diminished at pleasure, and was measured by a very sensitive thermometer. To ascertain the temperature in the soil where the other end was buried, it was only necessary to raise or lower the temperature of the water bath until the magnetic needle stood at zero, and then read the thermometer."

ELECTRIC LIGHTING AND THE BOARD OF TRADE.—A deputation of the Parliamentary Committee of the Board of Works for the Westminster District, introduced by Mr. W. H. Smith, M.P., and Lord Algernon Percy, M.P., had an interview on Thursday (March 15) with the President of the Board of Trade to ask for a postponement of the operation of the Electric Lighting Act of last Session, so far as Westminster is concerned, for a period of three years from the date of the passing of the measure. The views of the deputation were set forth in a memorial and were also stated by Mr. T. Horn, C.E., Mr. J. K. Aston, and Mr. Hamborg. They were to the effect that at present any proceedings taken under the Act must be of a speculative and experimental character; that no practical demand exists in the district for electric lighting, and unless it should be desired by a majority of ratepayers it ought not to be forced upon them; and that so far they did not possess sufficient experience as to which of the various schemes would be most beneficial to the public, or whether it would be more to the interest of the ratepayers to apply for a license on their behalf to adopt the new system or to allow provisional orders to be obtained by private companies. It was further contended that electric lighting did not at present commend itself to the public generally. The deputation suggested that the Government should bring in an Act containing general provisions for the supply of electricity, such provisions to be incorporated in any license or provisional order, and admitting of alterations from time to time should necessity arise for amending the private Acts of the patent companies. Chiefly and specially, however, the deputation urged that their object was to gain time, so that they might not be hampered in the future by the creation of vested interests, and they put in this plea not in the interest of the gas companies, but to leave themselves free hereafter to adopt whatever system might appear the best.—Mr. Chamberlain, in reply, said he would notice first the practical suggestion made, viz., that the Government should introduce a general Act containing provisions that might be introduced into Bills promoted by private companies. In his opinion nothing could be more inadvisable, having regard to the general principle of local government and to local circumstances, than such a proceeding. They had, as a matter of fact, already obtained the greatest possible security in this respect in the model clauses which had been prepared by the Board of Trade. It had been stated that the Act did not afford guarantee for continuous supply, nor safeguards as to price; but the contrary was the case. Continuous supply was compulsory, except that a period of six months' grace was allowed at the commencement of an installation, and the method of charging for the supply of electricity was ordered to be in accordance with one of three accepted systems. As to the question of postponing the operation of the Act, the proposal was virtually the same as was submitted to him before the measure was passed; but he was bound to say that to proceed in the way suggested would be in direct contravention of the principle of the Act. That principle was that the public should have the chance of getting the electric light, and if the local authorities were not ready to supply it others should be allowed to do so. In Westminster they might not be prepared to run the risk and to burden their rates with the cost of experiments; and if he were to express his private rather than his official opinion in the matter, he should say they were very wise in taking that view, and that they would not be justified in incurring any great expenditure. But that was no reason why they should stand in the way of private persons who might be willing to take the risk. The local authorities were amply protected. They could appear before the Board of Trade and take objection to any scheme proposed before a provisional order was granted, and after it is granted they would be in this strong position: If the experiment proved a success at the end of a few years—a really short term in the life of a municipality—they, as representing the ratepayers, could come in and take over the whole undertaking, merely purchasing the plant at its actual value at the time. Never before were such rights conferred by an Act of Parliament. They had security against the creation of a monopoly, while they were left free to watch an experiment carried out at the cost of other people. Under such circumstances he did not think it would be wise for any local authorities to put themselves in the way of the execution of the Act.—Mr. Horn explained that they did not wish to oppose themselves to scientific progress; all that they wished was time to consider the merits of the new system of illumination thoroughly.

CURRENT ENERGY.—IV.

BY OLIVER HEAVISIDE.

We have arrived at three distinct expressions for the potential energy of currents, involving line, surface, and volume integrations. Thus, confining ourselves first to a pair of linear circuits, we started with a surface-integral, derived from the properties of magnetic shells, viz., the integral amount of magnetic force passing through one circuit due to the current in the other. This amount, multiplied by the strength of current in the circuit for which the integral is reckoned, is the quantity upon whose variations the mutual forces depend. Now, the idea of magnetic force as a vector or directed quantity has become so widely spread and utilised that it might appear that the expression of the energy in terms of the number of lines of force through a circuit was a very natural one. In all modern explanations relating to magneto and dynamo machines, the lines of force are much employed. Yet this form for the energy is very artificial, and, in that respect, is like some other forms. For, although we may frequently merely consider the lines of force of the field in immediate proximity to a conductor, and the manner in which they cross the wire when it is moved, or when the source of the field is moved, thus producing variations in the integral amount of force (or of magnetic induction, to use the more general term, when induced magnetisation, notably that of iron, not here considered, is operative) through a circuit, yet to reckon up the integral amount a knowledge of the strength and direction of the magnetic force just about the wire is not sufficient. We require strictly to know the magnetic force all over an imagined surface, with its edge coinciding with the linear circuit. Choose one side for positive, one direction through it for the positive direction, and then by integration over the surface find the excess of the amount of force going through it in one over that in the reverse direction. This process may become singularly complex when the circuit has not a simple form, owing to the extraordinarily involved character of the surface, through which a selected line of force may pass again and again. In practical applications, however, we may simplify the process. Thus, in the case of a coil of closely-packed windings, say n in number, since each winding forms nearly a closed curve in itself, we may imagine a separate surface for every turn of wire, thus reducing the problem without sensible error to that of n distinct circuits of simple forms placed in a magnetic field. The sum of the amounts of force through the individual surfaces will plainly be almost precisely the same as through a single surface whose edge is bounded by the real circuit.

By a transformation we next obtain the mutual energy in terms of line-integrations following the course of the current, with a result most succinctly expressed in Neumann's formula, given at the end of Art. I., and we are able to recognise the very simple manner in which the different current elements may be considered to contribute to the result; and, following this up, we arrive at simple expressions for the mutual and self-energy of arbitrary distributions of current in terms of the currents and their vector-potentials, which are exactly analogous to the formulæ for electrostatic energy. And, by another transformation, given in Art. III., we obtain the energy in terms of the magnetic force alone.

Now, if we change the sign of the quantity we have called the potential energy of a current, which is always negative (being $= -\Sigma B^2/8\pi$, equation 12, p. 391) we obtain a quantity which is necessarily always positive. Calling it T, so that we have $T = \frac{1}{2}\Sigma\overline{AC}$, where C is the current and A the vector-potential, it will be shown later that T expresses the capacity the system has for performing work, which may be of various kinds, in virtue of the existence of the current, so that T may be strictly called the Energy of the system. Taking this for granted for the present, in order not to enter upon inductive phenomena, we may, however, remark in passing that we calculated the polential energy ($-$ T) in exactly the same manner as electrostatic energy may be calculated, from the mutual forces, to wit. P being the electrostatic potential, and ρ the density of electrification, $\frac{1}{2}\Sigma P\rho$ is the potential energy of the electrification, corresponding to $-\frac{1}{2}\Sigma\overline{AC}$. Now, $\frac{1}{2}\Sigma P\rho$ really represents the capacity the electrified system has for performing work, that is, its energy. It is always and necessarily positive, and, when referred to the dielectric medium, may be considered to express the potential energy arising from elastic forces due to displacements of some kind. The fact that the potential energy M, in the electro-magnetic case, is negative (resulting from attraction of similarly directed currents) is sufficient to show that it cannot represent the capacity for work of the current system. Yet the variations of M do represent the mechanical forces. So do those of T, any increase of one being equivalent to an equal decrease of the other. Therefore T might be the energy. But it could not be potential energy, for that tends to decrease; for instance, two movable circuits tend to move so that their potential energy decreases, with currents constant, and, therefore, so as to increase T. If, then, T be the energy, and it cannot be potential, it must be kinetic. And it is true that, considered as kinetic energy, it follows from strictly dynamical principles that T would tend to increase (with unchanged currents) by the motions resulting from the actions upon movable parts. Without, then, any knowledge of inductive phenomena, we might hazard the conjecture that T represented the energy, and that it was kinetic; and from the properties of kinetic energy all the laws of induction would follow.

At present, however, let us merely examine how the different expressions for T tend to locate the energy. The original form (surface-integrals) is quite out of the question, even for a single linear circuit, to say nothing of an arbitrary system of current, whether in wires or diffused in large conductors.

The form $T = \frac{1}{2}\Sigma\overline{AC}$, however, is more definite. Here any unit volume where the density of the current is C contributes $\frac{1}{2}\overline{AC}$ to the total, and of course space, where there is no current, contributes nothing. The summation extends throughout the current. Now, we know that there is something going on in a wire conveying a current; we know, for instance, that there is a transfer of energy from a battery or other source of electricity; therefore, so far, it would not be unreasonable to suppose the energy resides where the current resides. But observe that, upon this view, the energy at any spot would depend not merely upon the current there, but also upon the vector-potential there, and the latter depends upon the state of the whole system. Now, the energy at any place, whether potential arising from elastic displacements of matter tending to return to neutral positions, or kinetic, due to a motion going on, would obviously depend on the displacements or motions at the place considered, and not upon those in all parts of the system. Evidently, then, the expression $\frac{1}{2}\Sigma\overline{AC}$ does not locate the energy properly. Notice, also, that although the total is positive, yet the portion $\frac{1}{2}\overline{AC}$ in any particular unit volume would be positive or negative, according as the current and vector-potential were similarly or oppositely directed, and zero should they be perpendicular. We may therefore dismiss the idea of $\frac{1}{2}\overline{AC}$ representing the energy per unit volume or density of the energy.

But we have still the form $\Sigma B^2/8\pi$ at disposal. This is identically the same in amount as $\frac{1}{2}\Sigma\overline{AC}$, but indicates a very different distribution of energy. In a unit volume we have the amount $B^2/8\pi$, B being the strength of magnetic force there. Being a square, it is always positive. Thus,

Digitized by Google

not only have we the total positive, but every element of the sum is positive as well. And the energy at any place depends only upon the square of the magnetic force at the place, and not upon the state of all the rest of the system.

The conclusion is irresistible that we have got an expression for the energy which may correctly locate it in amount at different places. As to its distribution, although particular arrangements of current may be such as to leave certain spaces without magnetic force, yet, in general, the latter extends throughout all space. The portion of the energy residing in the space occupied by the current may be only a small fraction of the whole amount. And, even then, it depends on the magnetic force, and not upon the current density; although, of course, there is connection between the force and current in other ways.

[*Examples.*—In the case of a closed solenoid there is no external magnetic force. And if the current-layer be thin compared with the diameter nearly all the energy resides in the space enclosed by the current, and next to none in the current itself. In the case of a long, straight solenoid the internal energy is very great compared with the external; the force is uniform, of strength $4\pi C$, where C = current across unit length of the solenoid, except near the ends where the force falls off; hence the energy in any part of the internal space not near the ends is proportional to the volume.]

When, then, we set up a current in a conductor, a transmission of energy outwards at once begins, and not until it is completed does the current get steady. Theoretically it never quite gets steady, space is boundless, and the transmission of energy outwards never quite ceases; but, in general, the permanent state is, practically, reached very quickly, and then we have a definite amount of energy in every place where the magnetic force extends, falling off in density of distribution rapidly as we recede from the current. A medium of some kind to receive the energy is, of course, necessary.

If the energy be kinetic some kind of motion must be going on where there is magnetic force. One suggested form is a rotation of matter about the lines of force as axes. This should be of a frictionless character, for there is no loss of energy in a steady current except what can be accounted for in heating the conductor or by other work done. It is as if we had a frictionless fly-wheel, or immense number of fly-wheels somehow set moving by the establishment of a current in a circuit, and possessing in virtue of their motion a store of energy which can be afterwards utilised. The supply of energy from the battery may be stopped, and then the reserve store comes into action, is returned to the same wire, or to other conductors in its neighbourhood, creating the phenomena of induced currents.

But in the absence of reason to think the energy kinetic, we could equally well consider it potential, with the same distribution in space. We might, for instance, replace the steady motions of rotation last mentioned by displacements in the direction of the magnetic force, or by the same rotations as before, but stopped by counteracting elastic forces brought into play. The energy would be similar to that of a bent spring. On the removal of the E.M.F. that kept up the current, the forced state would be relaxed, the displacement cease, and the energy be set free again.

Before proceeding to the connection between energy and induction currents, we may notice some remarkable properties of the energy considered merely as expressing the quantity $\Sigma B^2/8\pi$ or $\frac{1}{2}\Sigma\overline{AC}$.

Let there be a given distribution of current C_1; corresponding thereto we have a definite distribution of magnetic force B_1, and also of vector-potential A_1. Briefly, they are related thus, $A_1 = \Sigma\frac{C_1}{r}$, $B_1 = \text{curl } A_1 = \Sigma\frac{D_1}{r}$ (if $D_1 = \text{curl } C_1$); and $4\pi C_1 = \text{curl } B_1$. All these relations have been fully explained. In addition we have $T_1 = \Sigma B_1^2/8\pi$, and B_1 being definite, so is T_1.

Consider the effect upon T of altering the magnetic force in any arbitrary manner, that is B_1 at any place is to be changed to some other value, say B, differing in general from B_1 both in direction and magnitude. We may make the alteration by bringing in another magnetic field, say B_2, of an arbitrary nature. At any point the actual magnetic force B will be the vector-sum of B_1 and B_2. Now T_1 becomes T where

$$T = \frac{1}{8\pi}\Sigma(B_1 + B_2)^2 = \frac{1}{8\pi}\Sigma B_1^2 + \frac{1}{8\pi}\Sigma B_2^2 + \frac{1}{4\pi}\Sigma\overline{B_1B_2} \quad (1)$$

$$= \quad T_1 + \quad T_2 + \quad T_{12} \text{ say.}$$

The energy is increased by $T_2 + T_{12}$. Here T_2 is the energy of the system B_2 by itself, and is essentially a positive quantity. But T_{12} containing products may be either positive or negative, so that whether the energy is increased or decreased is quite indefinite so far.

But now, instead of letting B_2 be quite arbitrary, let it be subjected to the condition that it shall not alter the current. We can then evaluate T_{12}. The original current C_1 must be still C_1, after the superposition of the second field, and no fresh current must be introduced in other places. C_1 being completely defined by the curl of B_1, it is evident that the condition imposed upon B_2 is that it shall have no curl anywhere.

If we have two *current* systems, we have seen that (equation 13, p. 391), $\Sigma\overline{B_1B_2} = 4\pi\Sigma\overline{A_1C_2}$, where B_1 and B_2 are the magnetic forces, A_1 the vector-potential of one current, and C_2 the other current. Therefore, if $C_2 = 0$, which involves curl $B_2 = 0$, we shall have $\Sigma\overline{B_1B_2} = 0$. This is suggestive, but does not exactly correspond to the circumstances considered in equations (1) above. For $C_2 = 0$ involves $B_2 = 0$; whereas in (1) B_2 is not to vanish, but merely to have no curl. Otherwise it may be arbitrary. Nevertheless, it may be readily shown that $\Sigma\overline{B_1B_2}$ really vanishes in (1) by considering the imposed property of B_2. When we say that its curl is nothing everywhere, we imply that nowhere can any closed curve be described so that the integral of B_2 once round it differs from zero. Now, B_1 consists entirely of closed tubes. Select one of them, and let it be of infinitely small section. The portion of $\Sigma\overline{B_1B_2}$ belonging to this tube is

$B_1 \times$ section of tube $\times$ integral of B_2 once round its length.

But $B_1 \times$ section is a constant for the same tube, and the last factor is zero, hence the portion of $\Sigma\overline{B_1B_2}$ is zero for that tube. Similarly it is zero for any other, and for all, and it follows that the whole summation $\Sigma\overline{B_1B_2} = 0$.

Consequently (1) becomes $T = T_1 + T_2$. Hence, if we alter the magnetic force of a current in any manner consistent with keeping the current the same, the energy is invariably *increased;* for T_2 is the sum of squares, and the products have gone out; *i.e.*, out of the infinite number of distributions of magnetic force which have the same curl (in amount $4\pi C_1$), the real distribution is that one which makes the energy an absolute minimum.

There are remarkable differences between the two fields of force signified by B_1 and B_2. B_1 has no convergence anywhere; that is its fundamental property. Its lines of force are all closed curves. It necessarily has curl somewhere. Quite apart from our having specified B_1 to have curl, we may show that if it have no convergence it must have curl. For, if the integral of B_1 be taken once round a closed line of force, thus always going with the force, or always against it, and its amount, necessarily differing from zero, be noted, and then we do the same for another closed line of force close to but within the first, the amount must be the same or different. If different, there is evidently curl in the space passed over in transferring one line of force to the other, and we need proceed no further. If the same, there is no curl on the whole. If so, we may go on to a third line of force within the second, and so on till we either find the integral change its value, or in the extreme case find ourselves reduced to a curve bounding an infinitely small area, with the same finite value of the integral, so that we have infinite density of curl. In electro-magnetism, the curl corresponds to $4\pi \times$ current density, so that the existence of closed lines

Digitized by Google

of force involves the existence of current somewhere, in fact passing through the closed lines.

Now consider B_2. It must have no curl anywhere. Describe any closed curve in the field. It cannot be made to coincide with a single line of force, for that would give curl at once. The integral of B_2 must be *nil*. Hence, since there is not a single closed line of force in the field, every line of force has a beginning and an end, and the system may be completely divided into tubes which are all terminated, or unclosed, or open. (In order to exclude getting infinite values for the energy, it should be understood that B_1 and B_2 vanish at infinity. And in the case of unclosed lines of force going out to infinity, we may terminate them upon an imaginary large surface enclosing the practical field of force.)

The field B_2 corresponds to that of a permanent magnet on the theory of magnetic matter, or north and south magnetism. This theory gives but an imperfect view of the force of a magnet, but just answers our purpose here. In a bar magnet uniformly magnetised there is positive magnetism at one end and negative at the other; and, in general, there may with irregular magnetisation be both surface and internal distributions of magnetism. The lines of force go from the positive to the negative magnetism always, and are thus all terminated or unclosed. The line integral of force round any close curve is always *nil*. The amount of magnetism anywhere is measured by the amount of convergence or divergence of the force, which convergence and divergence really constitute all the evidence there is of the existence of the matter.

Now, we may arrange our magnetism anyhow, the only restriction being that there is just as much positive as negative, which, interpreted, means that a line which is not closed on itself must have two ends (which nobody can deny); hence we can produce a field of force B_2 which is quite arbitrary, save the restriction that B_2 has no curl anywhere. And since we can arrange electric currents any how with the sole restriction that any line of current must have no ends, or be closed, we can produce another field of force B_1, which is arbitrary subject to B_1 having no convergence. Now superimpose the two fields, the currents and the magnets adding their forces. The result is an unconditionally arbitrary field of force, which has both curl and convergence.

Given, then, an arbitrary field B of unknown source, we may immediately divide it into two fields—one due to current, the other to magnetism. There is only one way of effecting the division, and no third course. For, measure the curl of B everywhere and construct the field, say B_1, which has just that curl and no convergence. Deduct the field B_1 from the field B, the residual field, say B_2, has obviously no curl, and has, therefore, convergence. Or we may start by finding the convergence of B_1, and construct the field, which has the same convergence but no curl; this will be the same B_2 as before, and, deducting it from B, will leave a field B_1, which has no convergence, and which, therefore, has curl. B_1 is due to current, B_2 to magnetism.

Now, the arbitrary field B might be divided into two fields in any number of ways, and in general equation (1) above would hold, it being, however, now permissible for both B_1 and B_2 to have curl and convergence as well as B, and T_{12} would not vanish. But of all these ways there is just one that makes T_{12} vanish, and when that is got there is a perfect separation of the closed from the unclosed tubes of force, the curl is confined to B_1 and the convergence to B_2. [These properties do not belong to magnetic force only, but apply to any continuous vector functions, displacements, velocities, &c., and have extensive applications in physics.] The work spent against magnetic force in carrying a unit pole from A to Z in the field B_2 is independent of the path followed, therefore depending only on the positions of A and Z, and hence we have a scalar-potential. On the other hand, a vector-potential is appropriate to the field B_1, in which the work spent is not independent of the path, although in space not occupied by current a scalar-potential may be used under restrictions. [Compare Theorems II. and III., p. 56 *ante*.]

In proving the minimum property above we applied it to a field of force due to currents. But it is easily seen to apply equally well to a field due to magnetism. Thus, let B_2 be given without curl, representing the field of a magnet, and consider how the quantity ΣB_2^2 is affected by altering the field in any way that does not introduce fresh magnetism. The auxiliary field B_1 must have no convergence, hence $\Sigma \overline{B_1 B_2} = 0$, and ΣB_2^2 becomes $\Sigma B_2^2 + \Sigma B_1^2$, and is, therefore, always increased. Hence ΣB_2^2 for the magnet is the least possible.

An application of the minimum property is to prove that one, and only one, solution exists for the magnetic force or the vector-potential when the current is given (or similarly for the force or scalar-potential when magnetism is given). Merely to illustrate the general course of argument take the case of a given system of current. Prove that there is one, and only one, distribution of magnetic force. Here we define magnetic force so that its curl shall be $4\pi \times$ current, and that it shall be without convergence. Assume that B_1 is a solution. We can show that, if we alter the magnetic force without altering the current, we always increase the quantity ΣB_1^2, and that ΣB_1^2 is, therefore, the least possible. That is to say, if B_1 is a solution, then ΣB_1^2 is a minimum. But ΣB_1^2, being always positive, is capable of being made a minimum, hence there must be a solution. That there is only one follows obviously by assuming there to be another, and showing that it is the same as the first.

It may be asked, and very naturally, what is the use of this when we know there is a solution, and have been working with it all along? Not much, certainly, in the present case. But when we are considering induced magnetisation and various other questions, the equations and conditions to be satisfied may become so complex that it may not be at all evident *à priori* that they are consistent with the existence of a single distribution of force, &c., free from ambiguity and impossibility. In such cases valuable evidence is obtainable by forming the expressions for the energy or analogous quantities, and investigating their minimum or maximum properties.

Consider next the mutual energy of two systems of current. Denoting these densities by C_1 and C_2 respectively we have (equation 13, p. 391)

$$T_{12} = \frac{1}{4\pi} \Sigma \overline{B_1 B_2} = \Sigma \overline{A_1 C_2} = \Sigma \overline{A_2 C_1}.$$

Now here C_1 is the current corresponding to the magnetic force B_1, and C_2 to B_2, and similarly for the vector-potentials. But since all alike have the property of absence of convergence we may equally well let C_1, C_2, A_1, A_2 stand for magnetic force. We have then six fields of force, all different, though related three and three, and we may arrange them in three pairs, so that their mutual energies are equal. As an example, if two coils of any form containing currents be so placed that either current sends no force on the whole through the other, the same will be true of another pair of currents so arranged that the magnetic force of one is represented by the current in one of the original circuits, and the force of the other by the vector-potential of the second of the original currents, and similarly the other pair of currents may be found.

Nor need we stop here, for we may do the same with the newly-obtained systems of magnetic force, and hence construct an unlimited number of pairs of fields which shall have the same mutual energy as a given pair. This may be symbolised thus:—Let B_1, B_2, B_3, B_4, B_5 be fields of force so related that $B_2 = \text{curl } B_1$, $B_3 = \text{curl } B_2$, and so on; and, similarly, let there be another set, with accents, similarly related. Then, for example, starting with B_3 and B'_3, we have, out of other combinations,

$\Sigma \overline{B_3 B'_3} = \Sigma \overline{B_2 B'_4} = \Sigma \overline{B_1 B'_5}$, and also $= \Sigma \overline{B_4 B'_2} = \Sigma \overline{B_5 B'_1}$, the summations extending in each case over the proper fields. We may have, however, merely superficial distributions to deal with.

To wind up the present article, there is a curious form in which the energy may be expressed, which I have not seen noticed, viz., in terms of the vector-potential of current and the scalar-potential of free electricity. Let a steady current be set up, say by a battery, so that we may locate the im-

Digitized by Google

pressed E.M.F.'s distinctly at a certain section or sections of the circuit; let the conductivity c be uniform, P the electrostatic, and A the vector-potential, then $T = \frac{c}{2} \Sigma PA_n$, where A_n denotes the normal component of A reckoned inwards, and the summation extends over the whole bounding surface of the circuit. This may be verified by Theorem I. relating to convergence (p. 55 *ante*); P being scalar, PA is a vector, and its surface-integral may be expressed in terms of its convergence within the enclosed space.

Since the potential P is discontinuous at the section of E.M.F. (one, for simplicity), we must cut the circuit there, thus producing an enclosed space which does not enter into itself as the closed conductor does, and reckon P differently for the two new surfaces formed, the values, of course, differing by an amount equal to the E.M.F.

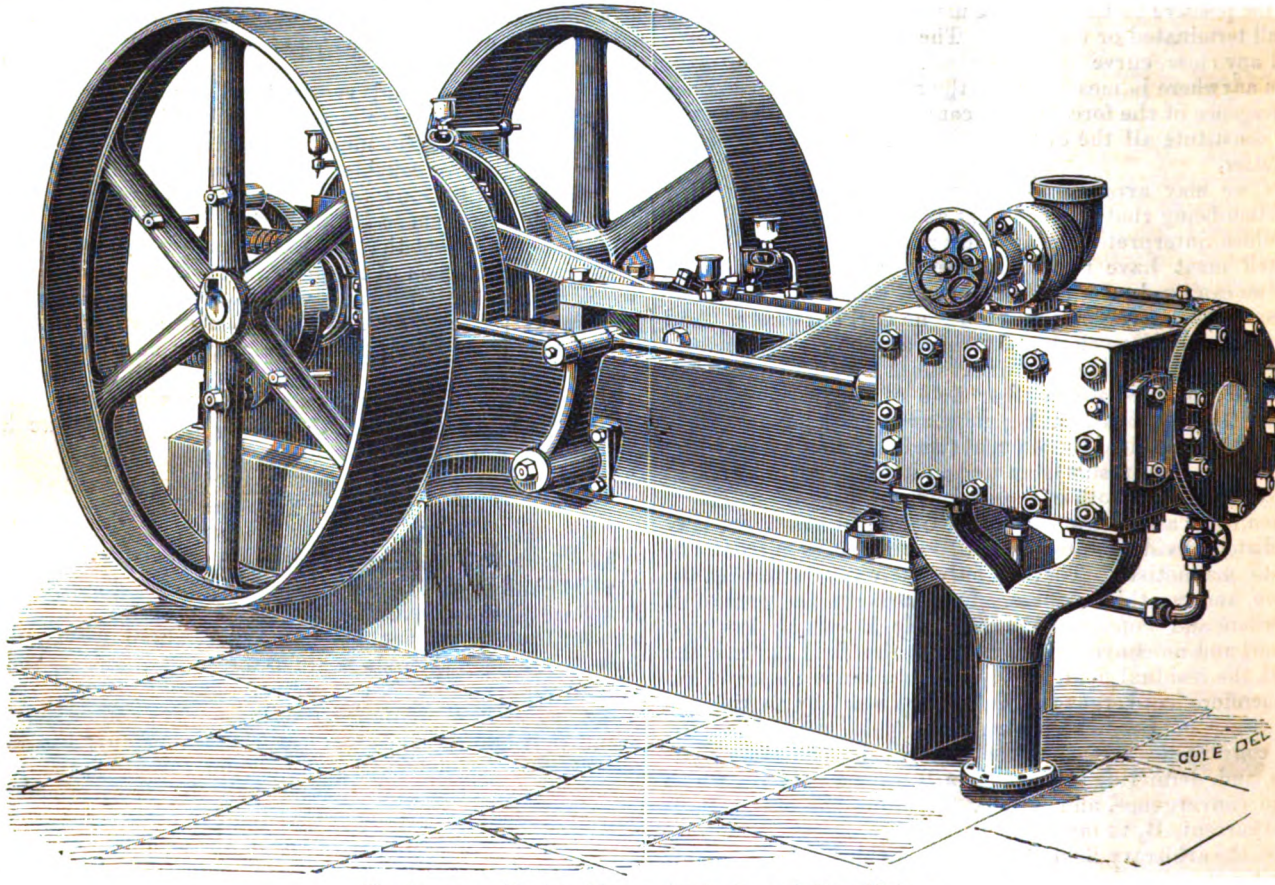
In general, with conductivity not uniform,

$$T = \frac{1}{2}\iint cPA_n dS + \frac{1}{2}\iiint P\,\overline{A\nabla c}\,dV$$

where dS and dV are elements of surface and of volume, and ∇c is the vector rate of increase of c.

EDISON'S SYSTEM AT WATERLOO STATION AND THE HOUSES OF PARLIAMENT.

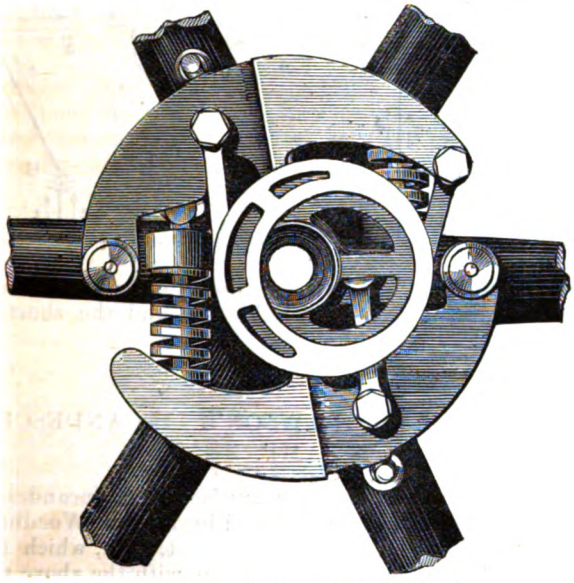
There is no doubt that the Edison installation at Waterloo Station is one of the best examples of electric lighting in England. The fact that the details of this system have been so carefully studied, and have been designed each to fulfil its exact duties makes the system one that always deserves the most careful investigation. We find that, although so much attention has already been given to details, there is still the closest supervision, and improvements are being constantly made. This is as it should be; theoretically a design may seem complete, but the experience gained by practice is sure to suggest modifications. We do not know that there is anything new to chronicle as regards the lamps, which are here of the ordinary A type; but in these installations a new steam motor has been used. So far as we know, only four of these engines are being used as yet in connection with the electric light in England—one at Waterloo, one at the Houses of Parliament, one at Messrs. Mather and Platt's, of Manchester, and one at the Holborn Viaduct Central Station. These engines are the Lawrence engines, as constructed by Messrs. Armington and Sims's Company, Providence, Rhode Island, U.S.A. The builders of these engines claim for them extreme simplicity, the absence of parts requiring frequent adjustment, great regularity of speed, small space required for engine and fly-wheel, and consequent rigidity in stationary and moving parts, the use of short and nearly parallel belts, and large bearings. The automatic cut-off regulator used is said to be original, and perfect in its operations. It is attached directly to the valve-rod, and varies the point of cut-off as the resistance requires from the commencement to seven-tenths of the stroke without changing the lead. It acts very quickly, and whatever the change in load or pressure of steam, the speed remains practically constant. The variation of speed from an extreme light load to the capacity of the engine does not exceed two per cent. The valve is perfectly balanced, and at all times surrounded by live steam. By its construction it permits full boiler pressure to be maintained in the cylinder up to the point of cut off. The engines are built of various types, from 19 h.-p. indicated non-condensing single engines to 236 h.-p., and double engines from 184 to 472 h.-p. The report of the Edison Company is extremely favourable to these engines. We give a view of one of them, also two views of the governor. The valve has no packing rings, but is a tube enlarged at each



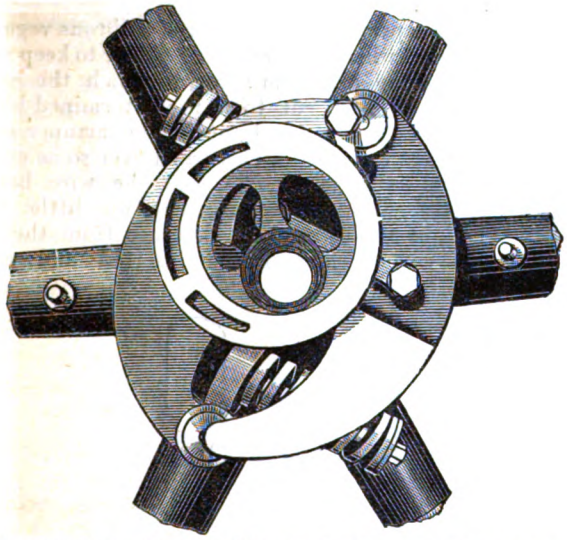
The Lawrence Engine: Messrs. Armington and Sims, Makers.

Digitized by Google

end, and after being turned and having the steam edges finished, is ground to size with a lead lap. Steam is taken around the outer middle part of the valve, which is thus in equilibrium, the exhaust taking place over the ends and into a Y branch pipe that is led vertically downwards. Small bonnets at each end of the valve chest enable the valve to be got at without removing the main cover. The valve in the 125 horse-power engine is $5\frac{1}{4}$in. diameter, and having double admission opening, gives a port opening equivalent to 30in. long by $2\frac{1}{8}$in. in width. The working travel of this size would be 3in., with an extreme of $5\frac{3}{8}$in. The valve motion is so arranged that the steam admission can be varied by the governor from the lead of 1-32in. to the $\frac{5}{8}$th of the stroke. The piston is made very light, and has two rings. The cross-head is of cast iron, with gibs at bottom, which are to be set out with liners as wear takes place. The crosshead pin is of steel, running through a steel bush flattened top and bottom. One fault, if fault it may be called, of this engine is in the difficulty of obtaining access to the steel pin. The shaft is of "gun iron" or air furnace cast iron, and the disc is shrunk upon it before finally being trued up.



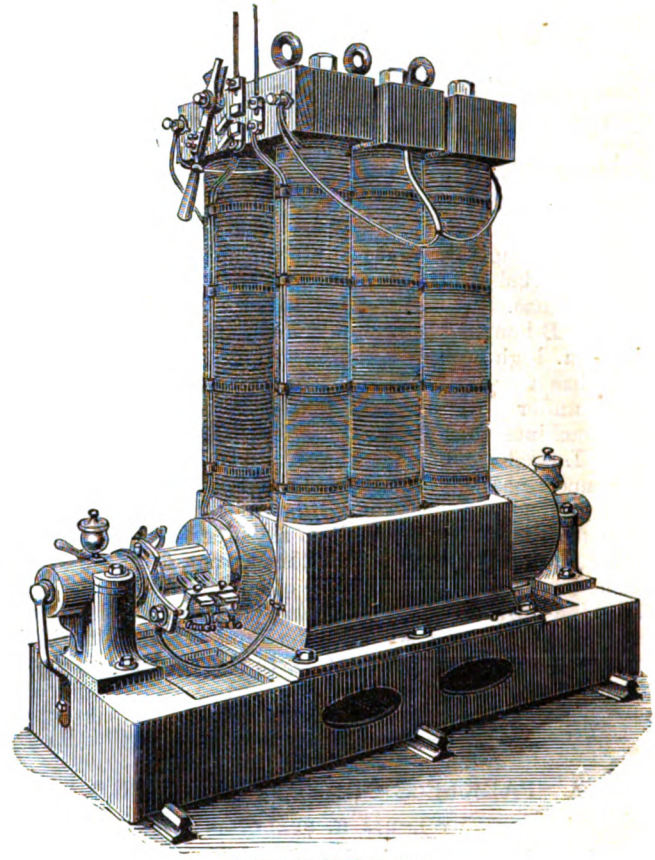
Governor to Armington and Sims's Engine.



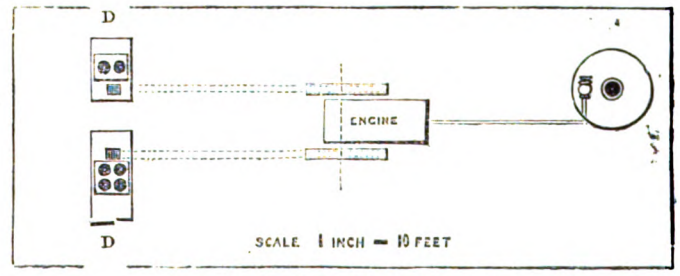
Governor to Armington and Sims's Engine.—Another position.

The governing arrangements consist of two excentrics on the main shafts, each of which is movable and controlled by the action of two suspended weights contained in a drum. These parts are all carried on the main shaft, the excentrics being movable on the shaft itself, and the weight carried on a pin going through a hole by the regulator drum. When the weight is by the rotation thrown outwards it carries by means of a link the outer excentric in one direction, but the inner excentric is by the outward motion of the opposite weight carried in the opposite direction. Thus the one excentric changes the throw and the other the real centre of the combined or double excentric. Another weight on the opposite side is used merely for balance, and is fastened to the inner excentric. The returning or balancing springs are arranged to be always in compression, being seated upon a small bracket through which a rod passes and takes hold of a cap on the opposite end.

The lubricating arrangements are worked out with considerable care, as is necessary in high-speed engines, their success in continuous running depending largely upon this detail. The supply of oil may be regulated by merely screwing up or down the cover and inserting fresh oil through the small hole in the cover. A Siebert sight-feed lubricator is used on the steam pipe. A horizontal pipe is brought from the main steam pipe outwards, then fitted with a cock, and turned down. In this unprotected pipe the steam condenses, and the water column thus formed is admitted by a valve to the under side of a cup filled with oil, the only escape being at the top through a central vertical pipe leading to the gauge glass which communicates by a pipe and valve with a lower part of the main steam pipe. The gauge glass being also filled with "condense water," the oil passes from the small interior pipe with a velocity due to the head



Edison's K Dynamo.



Arrangement of Machines at Waterloo.

Digitized by Google

of water up through the water in the gauge glass, being readily seen in doing so, and being capable of all ranges of regulation, from a steady stream to one drop in three minutes.

At these installations Edison Z, L, and K dynamos are used. The Z dynamo is intended to produce a current for 60 A (16 candle-power) or 120 B (8 candle-power) lamps. It occupies a floor space of 45in. by 39in., has a height of 6ft., weighs 3,000lb., and makes 1,200 revolutions per minute, with a pulley of 6in. face and 10in. diameter. It is reckoned that this machine requires about 10 horse-power. The first Z dynamo was fixed September 28, 1881, in the mill of Mr. James Harrison, Newburgh, N.Y., and up to September 1, 1882, some seventy installations of similar machines were made. The L dynamo is intended to generate a current for 150 A or 300 B lamps. It occupies a floor space 60in. by 39in., has a height of 6ft. 6in., weighs 6,000lb., and uses about 19 horse-power at the normal speed of 900 revolutions per minute. The first L dynamo was sent out from the works on August 4, 1882. To look at, the L machine is a double Z, while the K machine is a treble Z, that is, while the Z dynamo has one electro-magnet, the L has two, and the K three. The K dynamo, illustrated on p. 441, is somewhat new to this country. Machines of this type were exhibited at the late Munich Exhibition, as will be seen on reference to our report. Although the first of this type of machines did not leave the workshops till June 3, 1882, a number of them are already in use. It is intended to supply current for 250 A or 500 B lamps. It occupies floor space 70in. by 39in., is 6ft. 6in. high, weighs 8,250lb., makes 900 revolutions per minute, has a pulley with 9in. face and 14in. diameter, and requires under normal conditions 35 horse-power.

The machines used at the Waterloo installation are one Z and one L machine, arranged as shown in the plan on p. 441. Two K machines will be used for the work at the Houses of Parliament. One K machine will be sufficient to generate the current for the lamps, but the two machines will usually run together, each supplying one-half the current, except in case of accident to one machine, when the other would be called upon to do all the work. Great care is being taken to provide against every emergency, and we have no doubt the result will be complete success. We shall return to this subject again, and illustrate the fittings to be used.

A SPARKLESS CURRENT-BREAKER.*

BY LOUIS H. SPELLIER.

The fact that the spark of the induced current of electro-magnetic instruments will destroy the contact surfaces by which the making and breaking of the circuit is effected is very keenly felt on current-breakers for electro-magnetic time telegraphs.

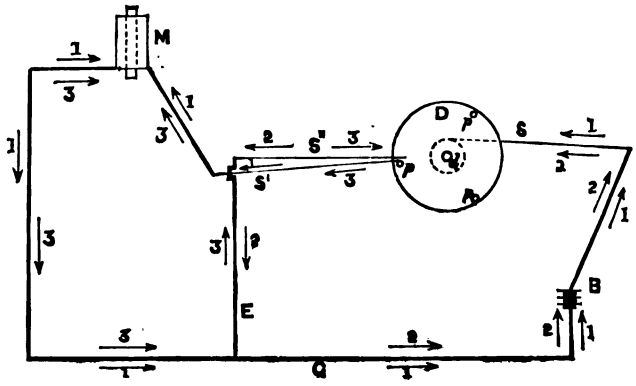
A device for the purpose of obviating the spark, invented by Dr. Hipp, has been in use successfully for some years at Geneva, to distribute astronomical time through the different sections of that city.

The writer presents in the accompanying diagram a device of his own for the same purpose, which, he believes, will commend itself for simplicity as well as for effectiveness.

With the exception of an additional contact spring, S″, the current-breaker is the same as described in the *Journal of the Franklin Institute*, August number, 1882.

The metal disc D is fastened to the axle of the escape-wheel of a clock, and has as many platinum pins, *p*, attached vertically upon its face, as there are openings and closings of the circuit needed during the time it completes one revolution. *d* is a platinum disc, fastened to the pin-bearing disc; S and S′ are two contact springs. The spring S rests upon the platinum disc, while S′ is to make the contact with the pins *p*. When the disc moves with the escape-wheel of the clock, and the spring S′ comes in contact with one of the pins, *p*, the circuit of the battery is completed, and broken when removed from it.

In the diagram D represents the current-breaker, B the battery, M the electro-magnet, and G the ground conductor. The spring S′ is in contact with a pin, and thereby completes the circuit. The current now takes the course as shown by the arrows 1. The contact spring S″ is placed a little higher than S′, and, therefore, does not yet touch the pin *p*. But, as soon as D moves on again, S″ will, a moment before S′ leaves the pin, come also in contact with it; at this moment S″ will make a short circuit through the conductor E, and the course of the battery current becomes that of the arrows 2, while the induced current of M, at the moment the short



circuit is made, takes the course as indicated by the arrows 3. A moment after S′ leaves *p*, S″ follows it, and the short circuit of the battery is also broken.

* From the *Journal of the Franklin Institute* for March, 1883.

WOODHOUSE AND RAWSON'S INCANDESCENT LAMP.

Certain modifications in the manufacture of incandescent lamps have recently been introduced by Messrs. Woodhouse and Rawson, of 11, Queen Victoria-street, E.C., which have resulted in the production of a lamp with the above title. With the help of our illustrations and a short description we think our readers will readily grasp the details of its manufacture.

The filaments are prepared from stuff of a fibrous vegetable nature, by processes which the inventors prefer to keep secret for the present. The platinum wires, to which the carbon filament is affixed, are first cut to a pre-determined length, after which the ends are flattened out in the manner shown in Fig. 1 (A); these ends are then turned over so as each to form a small tube as in Fig. 1 (B), and the wire bent to the shape shown, the ends next the two little tubes being bent at right angles a short distance from the tube. After this the carbon filament is inserted and firmly

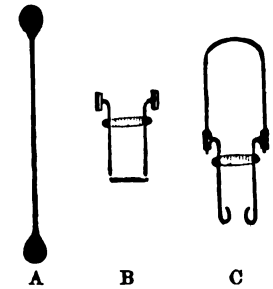


FIG. 1.—Showing the Method of Attaching the Filament to the Platinum Wires.

fixed in its place by cement, Fig. 1 (C). A glass yoke is fused on to both platinum wires as a stay, by means of which to hold them when they are cut at the bottom and their ends looped up, as shown in the above figures. The whole, wires and filament, is then inserted in the glass globe through the neck, held in its proper place, and the neck sealed. It only remains for the globe to be exhausted; this is done through the top, and the globe finally sealed, when the lamp has the appearance shown in Fig. 2.

The complete lamp is then placed on a circuit, run for a certain length of time, and the E.M.F. required for it ascertained and marked on the globe.

Digitized by Google

The processes of manufacture are consecutive, and are almost all performed by girls, who are preferred by the makers as being cheaper, and having better eyes and more delicate hands for the work than men. By the side of the lamp we show (Fig. 2) a form of holder patented by the makers. As will be seen, good contact is ensured by the spiral springs, which tend to keep the platinum hooks always in firm contact with the former. The three brass prongs have sufficient spring in them to grasp the body of the lamp tight and keep it steady, whilst they do not put too much strain on the platinum wires. The holder can be adapted to ordinary gas-fittings. Our illustration shows it screwed into a wall bracket. We may mention that the lamp illustrated above is of 20 candle-power, and is made to work with from 10 to 100 volts; from experience, however, it has been found that these lamps when constructed to work with from 40 to 50 volts are found to be the most satisfactory.

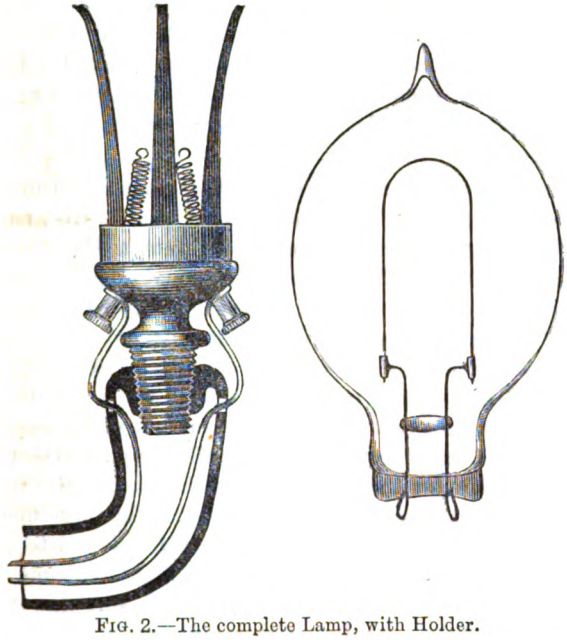

Fig. 2.—The complete Lamp, with Holder.

Another form of the above lamp is fitted with a brass collar filled with cement. In this lamp the platinum wires are left straight, and have copper ones soldered on to them; these latter project beyond the cement in the shape of hooks. The object of the brass collar and cement is to strengthen the neck of the lamp and add to its appearance. The makers find that our Continental friends prefer this shape.

In Fig. 3 is shown a full size engraving of a little lamp of one candle-power, made for surgical purposes. The makers turn out one rather larger than the above of three candle-

Fig. 3.—Lamp for Surgical purposes (full size).

power, for theatrical use, which is coloured by a special process, by means of which all blistering from heat is avoided. They also make lamps specially with the view to their use with batteries the resistance of which is kept low, so that they can be run with an E.M.F. of three to four volts. We may add that Messrs. Woodhouse and Rawson do not confine themselves to the manufacture of their own lamps, but have for some time past been, and are now, engaged in manufacturing and experimenting for the patentees of other lamps. Specimens of these lamps can be seen, amongst other places, at the Westminster Aquarium, where they are being used by Messrs. Goulard and Gibbs, the exhibitors of a new system of current regulation. Some coloured lamps will also be found in the goldfish tank.

STUDENTS' COLUMNS.

CITY AND GUILDS EXAMINATIONS.

The solutions in this number are solutions to some of the "*Honours*" questions in the paper hitherto considered, by E. C. Rimington, Esq. (School of Electrical Engineering), 12, Princes-street, Regent-street.

17. What is meant by the "efficiency of an electromotor?" Explain in detail, and give sketches of the method you would employ to measure this efficiency. Give the results that have been obtained with magneto and dynamo machines used as motors.

Ans. The electrical efficiency of an electromotor is the ratio between the power put electrically into the motor and the useful portion of this power which appears as mechanical work. The efficiency of a motor, however, does not depend entirely on itself, but also on the back E.M.F. it generates in rotating as related to the E.M.F. of the generator. The nearer the former approaches the latter the greater the percentage of power given out by the motor with relation to that put into the generator.

To measure the efficiency of a motor, take the E.M.F. at the terminals, and the current passing through it, then, if f be this efficiency, $f = \frac{e - C\rho}{e}$, where e = E.M.F. at terminals, C = current and ρ = internal resistance of the motor when at rest, for $f = \frac{E}{e}$ and $E = e - C\rho$, where E is the E.M.F. in the coils of the motor.

M. Marcel Deprez recently transmitted power from Miesbach to Munich, a distance of over 34 miles, through a double line of telegraph wire. He employed two similar Gramme dynamos, wound with high-resistance coils. The resistance of each machine was 470 ohms, while the line was 950. The speed of the generator was 2,100 revolutions, that of the motor 1,400. The E.M.F. of the generator at terminals = 2,400 volts, that of motor = 1,600. The mechanical efficiency was said to be about 32 per cent.

18. In what case would you recommend the employment of water transmission, and in what cases electrical transmission of power?

Ans. Transmission of power by water may be effected economically when a low speed and high pressure are required over short distances. The viscosity of water being very great, a great deal of power is wasted by the friction of the water on itself, and much more at low pressures with a large quantity flowing than at high pressure with a small quantity.

The electric transmission of power can be best employed when a high speed is required over long distances. The longer the distance the power is to be transmitted, the higher should be the E.M.F. of the generator and the back E.M.F. of the motor.

19. Describe, with sketches, the methods in detail of using a secondary battery to make an electric light independent of fluctuations in the speed of a dynamo—first, when the generator is a "series dynamo;" second, when it is a "shunt dynamo."

Ans. When the dynamo is a shunt one the accumulators, arranged in series so as to have the same E.M.F. that is desired to be maintained between the positive and negative leads, are generally employed as a shunt on the external circuit.

When the dynamo is a series one the batteries can be employed in the same manner, but an automatic cut out should be placed in the circuit between them and the dynamo, so that if the E.M.F. at the terminals of the dynamo falls below that at the terminals of the batteries, through great decrease in the speed of the engine or any other cause, the battery circuit is instantly broken. If this precaution be not taken, and the batteries should begin to discharge through the dynamo, its polarity will be reversed, and the combined strength of the current from the machine and the accumulators would probably burn up the former. In the case of the shunt dynamo, however, the current from the batteries, if they happened to discharge through the machine, would not reverse its polarity, as the current would flow in the same direction round the field-magnets as when the machine was exciting them.

Another disadvantage consequent on using a series dynamo in combination with accumulators is that the latter cannot be put on until the dynamo has been run through some resistance to enable it to get up sufficient E.M.F. to overcome that of the accumulators.

THE ELECTRICIAN.

TO CORRESPONDENTS.

All letters intended for insertion in THE ELECTRICIAN, *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

All communications to be addressed to 396, *Strand, London, W.C.*

We cannot undertake to return drawings or manuscripts, and must, therefore, request Correspondents to keep copies.

ANSWERS TO CORRESPONDENTS.

SUBSCRIBER.—*Eligibility consists in approval of the Council and the members. Any gentleman desirous of admission obtains a nomination form from the Secretary,* 4, *Broad Sanctuary, and the necessary signatures. The gentlemen who sign the form are really sponsors, and a grave responsibility rests upon them. The nomination is submitted to the Council, approved or rejected. The members signify their approval of the Council's action by ballot at an ordinary meeting.*

ELECTRIC.—*Similar suggestions to yours have been frequently put forward in these columns both by correspondents and ourselves.* (1) *No doubt more light would be almost, if not quite, as beneficial as more police.* (2) *Your suggestion as to an arc light for steamers has been advocated over and over again since the disasters you mention, but nobody seems to have taken it up yet.*

C. E. M. (BUCKHURST HILL).—(1) *Do not use two contact breakers.* (2) *It is against our rule to give prices. Write to the makers* (see CORRESPONDENCE, *p.* 446). *For wire the prices differ considerably. Write to Messrs. Elliott Brothers, or Messrs. Clark, Muirhead, and Co., or Messrs. Johnston Brothers, or Messrs. Glover. These firms will serve you well, and especially so if large quantities of wire are wanted.*

H. MEIER (CALAIS).—*It is very probable that we shall give a description of the small portable battery you mention. The lecture referred to will not, we think, be published more fully than we have given it. We do not think of republishing the articles. Sir F. Bramwell's address is* 37, *Great George-street, London, S.W.*

D. M. (A YOUNG ELECTRICIAN).—*We cannot publish any fuller report of the lecture you mention than that given in our last issue. For the date on which the lecture is to be redelivered and any other particulars you had better write to the secretary of the Institute, South Grove, Highgate.*

THE CITY AND GUILDS OF LONDON INSTITUTE.

The report to the governors of the above institute for the year 1882, presented at their meeting on the 14th inst., is now before us, and it would hardly be possible to overstate the encouragement it will afford to all persons interested in the promotion of technical education. From the very first, the movement inaugurated by the City of London and its ancient guilds has been an assured success. True, the character of the instruction and the results of the examinations have been, and will continue to be for a long while yet to come, subjects of criticism; and quite legitimately so, for it is only by the lessons of experience, and the sharp eyes of lookers-on that such schemes can be moulded into perfect working order. Pending the completion of the Finsbury Institute, and again that of the central building at Kensington, the work must necessarily be carried forward on tentative lines; but the experience gained in the interval will enable the managers to cope with the then vastly increased area of education in a manner they could not have done had it come upon them quite suddenly and unprepared. As it is, the growth of the movement has been abnormal, and already is ahead of the teaching power at its command. The lack of competent teachers is, in fact, the chief difficulty at present to be contended against; but this is a want which the colleges themselves may be trusted to supply in due time.

The one great trouble which besets most institutes, and and on which some of them are, indeed, said to live, namely, financial embarrassment, does not threaten the City and Guilds Institute at all. It makes the usual appeals for material support, as a matter of course; but, unlike its companions above referred to, it can subsist very comfortably without those periodical spasms of vitality which poor people are compelled to suffer in order to enlist the sympathies of the rich. In the short space of three or four years something over £100,000 has been raised for building purposes alone; and the income for the past year, which reached the sum of £25,000, appears likely to be maintained. The mere mention of such figures is enough to drive the doers of non-technical good works to despair; perhaps, also, it may have some effect in disarming envious critics of the political sort who "want to know" what the City does with its money.

With such an income as this, and with the material support of the wealthy Livery Companies of the metropolis, almost all of whom have now given in their adhesion to the enterprise, there is every prospect of carrying out the work of technical education on a thorough and extensive scale. By scholarships granted to metropolitan schools or colleges, and by donations to provincial institutes, the liberality of the patrons is already finding useful outlets, and the munificent manner in which the central establishments are being fitted up affords proof that whatever money can do will be done. The importance of assisting affiliated schools is already recognised by the board, who express a hope that they may be able to support, in various parts of London and in the suburbs near to the houses of the workmen, classes in which technical instruction of a scientific kind, similar to that obtainable at the Finsbury College, may be established. It is stated that large additional funds will be required before we can place the British workman, in respect to facilities for technical instruction, on a level with his fellow workmen on the Continent. For our part, we should be inclined to suspect that the existing difference is rather in the men than in the facilities; but if it be true that money, and money only, will remove the difference, we have no apprehension as to its not being forthcoming when wanted.

One other difficulty as regards employers of artisans is referred to in the report, and is closely related to that just alluded to in respect to the men themselves. It is still a matter of regret, writes one of the hon. secretaries of the institute, that large employers of labour do not encourage

Digitized by Google

their *employés* to the same extent as is the case on the Continent to attend evening science and technical classes, and the committee feel that, without the co-operation of the manufacturers, technical classes cannot be attended as regularly nor as numerously as is to be desired. It is to be regretted that this appeal and the grounds on which it is made cannot be brought home to the understandings of employers. Still the attendances are steadily increasing, the students now attached to the several registered classes of the institute numbering over 4,000 persons, whilst at the London Institute alone there are 500. In proof of the growing interest taken in the subject, the Associated Chambers of Commerce only the other day adopted a resolution recommending that steps be taken as far as possible to provide technical instruction in the trades of the localities where any of its affiliated chambers exist, and suggesting that each such chamber should nominate a committee to promote the movement.

We are glad to notice in this relation that the City and Guilds Institute in London has set the example of teaching apprentices at reduced terms—apprenticeship standing in need of all the help and encouragement such institutes are able to afford. Many people think that the bad repute into which apprenticeship has fallen in this country has something to do with the backwardness of our skilled artisans, compared with those of such countries as Germany and France. Dr. Siemens's remarks on this head at the distribution of prizes in December last, a full account of which is appended to the present report, are well deserving of attention. We cannot, perhaps, revert to the system of the Middle Ages, nor revive those powers of the guilds which they lost only in quite recent times. But we may do much to elevate art and manufacture to a higher and nobler level, and to teach both master and man to be proud of their calling—too proud of it to permit competition prices to rule, on the one hand, against honest productions, or, on the other, to regard tenpence an hour as the sole aim and object of producing. To these ends the system of technical education of which the City and Guilds Institute is the chief centre will largely contribute, by supplying that fundamental knowledge without which all handicraft is liable to become mechanical, unprogressive, and slipshod.

CORRESPONDENCE.

PORTABLE LAMP.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I beg to inform "One in the Dark" that such an apparatus as he requires could be made, but it would be on a much larger scale than the one given by Mr. C. J. Clark. He would require an incandescent lamp of the platinum type, with a filament of very low resistance, and a portable bichromate battery. The plates could be arranged as those in an accumulator, with a small space between them to allow the liquid to circulate freely. A battery containing six carbon plates 4 × 3 × ¼in., and five zinc plates 4 × 3 × 1-32in. in a solution of bichromate of potash two ounces, sulphuric acid one ounce, water 12 ounces. This would bring to incandescence a piece of platinum wire 1in. long, No. 36 gauge, and give "One in the Dark" sufficient light to read his music by. The time this battery would remain in action depends upon the amount of solution in the cell. The plates would require a space of 4 × 3 × 2in. The size of the outer cell would be determined by himself; the larger it is the longer the lamp will burn. He could carry this in his hand or in his pocket. Trusting this is sufficient.—Yours, &c.,

R. BOWMAN.

Cadby's Steam Works, Leather-lane, E.C.

PLATINISING CARBONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should be glad if you or one of the readers of your interesting journal could explain how it is that a greater lighting power, combined with less resistance, is obtained by platinising the filament of an incandescent lamp. I understand that Zanni platinises a filament, and in some cases deposits an outer coating of carbon, thereby obtaining the above-mentioned advantages.—Yours, &c.,

AN INQUIRER.

THE TELEPHONE CASE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I entertain the opinion that one very important point was apparently overlooked in the telephone case, which is this, that the production of audible sounds, or rather (as I think the judgment calls them) articulate sounds, is not a *manufacture*, and therefore not the subject of a patent; and the great difficulty is to determine how far the production of that class of sounds is due to electricity, and how far to the invention. One crucial test as to the validity of the patent is this—does or does it not claim the manufacture of instruments similar to that exhibited at Glasgow? The point relied on by the Court to show that the patent was not anticipated by that disclosure, namely, that it could not at that time be worked because the then state of knowledge was not sufficient to enable people to do so—although it can now be used for that purpose—appears to me to involve this, that the patentee can claim the use of subsequent discoveries not made by himself, which is inconsistent with the Act limiting monopolies to the true and first inventor. I think both the owners of that patent, as well as many other patentees, forget the rule that, though you can have a valid patent for applying a new contrivance to an old object, yet you cannot have a patent for applying an old contrivance to a new object. As a quaint old judge put it, "If all mankind had been accustomed to eat soup with a spoon you could not have a patent for eating peas with a spoon." Electricity belongs to all mankind, and the use of it cannot be monopolised. If Graham Bell's invention is *essential* to the result, then, by confining himself to his invention, he will secure the monopoly; but the patent will not be valid if he claims more than the instrument that he has actually invented, or colourable evasions of it. "If the whole is not new it is hanging terrors over them," said the judge in one case which, I think, has never been disputed.—Yours, &c.,

J. A. S.

THE SOCIETY OF TELEGRAPH ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The Society of Telegraph Engineers was started in 1871, and soon attained a position in the scientific world which gave promise of an ever-increasing reputation with increasing years. This early promise was, however, not long fulfilled, and a few years ago the friends of the young institution had to see that, far from bettering, or even maintaining, its ground as a scientific body, it seemed to be steadily subsiding into an assemblage of telegraphists and telegraph engineers. Although the domain of electricity was daily becoming more and more extensive, we, as a body, seemed to be contracting our sphere of usefulness within that small portion of it represented by the requirements of electric telegraphy (used in its widest sense), leaving the rest of the field almost, if not entirely, untouched.

Under these circumstances the large and increasing body of pure electricians and workers in the other hundred and one applications of electricity, feeling that there was no place for

Digitized by Google

them in our midst, did not join us as eagerly as could be wished, while of those who did enter our ranks, or have been with us from the first, very few have taken any interest in our proceedings.

It was seen that such a state of things must, in the end, prove fatal to the society, and so, about 1879, its friends proposed to alter its title so as to embrace all classes of labourers in the allied fields of electricity and magnetism. In December, 1880, the new title was proclaimed—the Society of Telegraph Engineers and of Electricians—and it was hoped that, with the new title, we would make a new start, and gather into our net all the wealth of electric and magnetic science.

Judging, however, from the contents of the last two volumes of the *Journal* we find, with regret, that there has been little or no change in this respect. We are still little else than telegraphists, for the great majority of the papers read at our meetings have been by telegraphists on telegraphic subjects. Abstract papers, and, generally, all papers on non-telegraphic subjects are still taken elsewhere, and we frequently see distinguished members of our body—even members of our council—reading papers before the Royal and Physical Societies, the Society of Arts, and the Institutions of Civil and Mechanical Engineers, most, if not all of which, should, in fairness, be given to us.

This is an unpleasant, not to say humiliating, state of things, to which, in all earnestness, I beg to draw the attention of those distinguished members mentioned above, and, generally, all members of the society, reminding them of the old saw—united we stand, divided we fall.—Yours, &c.,

London, March 19, 1883. J. J. Fahie, M.S.T.E. & E.

THE EFFICIENCY OF ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: It is of the greatest interest, both to scientific men and to the general public, to know what is the real depreciation which takes place in the efficiency of accumulators. Will not Professor Ayrton or Dr. Gladstone tell the world once for all what is the observed loss of efficiency in a cell that has been in use for, say, 1,000 hours, and in what ratio the loss progresses?

Professor Ayrton showed accumulators in work at the London Institution, and I believe he has had some for a considerable time at the buildings of the City and Guilds of London Institute. He can surely set this question at rest by mentioning the actual loss observed in these specimens.—Yours, &c., I. T.

March 20, 1883.

CLARKE'S PORTABLE BATTERY, GAS LIGHTER, &c.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have observed of late several questions in your paper on the subject of my patent electric gas lighters and induction coils and batteries. I beg to inform your correspondents that I have now transferred my inventions to the Electric Portable Battery and Gas Igniting Company (Limited), whose works are at Clegg's Court, Salford, Manchester. I shall be happy to give your correspondents any information they may desire if they will kindly communicate with me direct.—Yours, &c. Charles L. Clarke.

The Electric Portable Battery and Gas Igniting Company (Limited).

GUTTA PERCHA.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Can any of your readers give information as to the cost of gutta percha per pound, in the condition in which it is put upon the conducting wires of cables, also upon the wires laid under town streets? The price of the uncleansed material seems to vary largely, judging from the following items given in the *Public Ledger*:—Gutta percha, good to fine, per lb., 1s. 8d. to 3s. 9d.; low to medium, 3d. to 1s. 7d.

Likewise, can any of your readers give details of the preparation of gutta percha by the Malays? What proportions of scraped bark and cocoa nut oil do they work in? What physical changes does it undergo from the time of leaving the tree until it reaches the hands of the merchant? Do its physical conditions slowly change at all during the first month after the Malays have boiled it?—Yours, &c.,

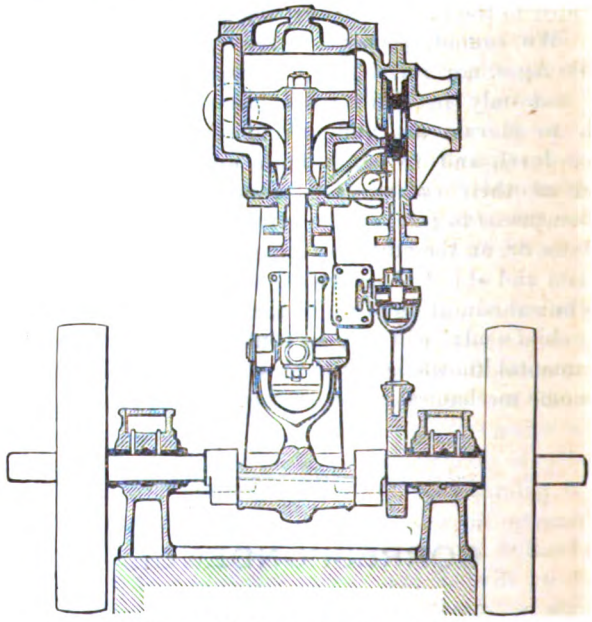
W. H. Harrison.

3, St. Michael's-terrace, Folkestone.

THE FARCOT COMPOUND ENGINE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Six months ago you were good enough to illustrate an economical type of compound engine specially adapted for small installations of the electric light. This engine has already been applied to such purpose with exceedingly good results, and I now find that a design somewhat similar is being adopted in France by the principal lighting companies. I allude to the Farcot high speed compound engine, of which I enclose a sketch, from which it will be seen that although in outward form it is very like the Kingdom engine, illustrated by you, it differs very much in the arrangement of the high and low pressure cylinders. These are cast together in one piece, and communicate one with the other, thus dispensing with the intermediate stuffing box and cylinder cover, the steam, after doing its work in the lower cylinder, being expanded in the upper so as to make the return stroke.



Farcot's Engine for Electric Light.

Another novelty in this engine is the arrangement of the governor, which gives complete control over the speed in a simple manner by means of a weighted hydraulic piston connected to a small centrifugal pump worked from the crank shaft. As the speed increases so does the quantity of water delivered by the pump, and the piston is raised, shutting the throttle valve.

The engine I examined is one of a number ordered by the Société Electrique Gramme, and has given excellent diagrams, which I should be pleased to show to any one interested in such matters.—Yours, &c.,

Paris, March 9. Killingworth Hedges.

SAFE WORKING CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Your correspondent, "H. B.," who apparently is the compiler of your Supplement No. 2, has worked from a

Digitized by Google

formula giving the rise of temperature per second which *would* take place in a wire through which an electric current is flowing *if* the wire lost no heat by radiation, convection, or conduction. We in practice have nothing to do with such hypothetical cases. I gave the true theory of, and the experiments upon, the currents which, in passing through wires of different diameters, produce the same permanent rise of temperature, at the British Association, last year, and in *The Electrician*, last September. I have lately seen some examples correctly worked out in an admirable little book, "Day's Electric Light Arithmetic."—Yours, &c.,

GEORGE FORBES.

34, Great George-street, Westminster,
March 20, 1883.

THE INSTITUTION OF CIVIL ENGINEERS.

The third of the series of six lectures on the applications of electricity was delivered on Thursday evening, the 15th March, by Dr. C. William Siemens, F.R.S., M. Inst. C.E. The subject was "The Electrical Transmission and Storage of Power." The following is an abstract of the lecture :—

Dr. SIEMENS, in opening the discourse, adverted to the object the Council had in view in organising these occasional lectures, which were not to be lectures upon general topics, but the outcome of such special study and practical experience as members of the institution had exceptional opportunities of acquiring in the course of their professional occupation. The subject to be dealt with during the present session was that of electricity. Already telegraphy had been brought forward by Mr. W. H. Preece, and telephonic communication by Sir Frederick Bramwell.

Thus far electricity had been introduced as the swift and subtle agency by which signals were produced either by mechanical means or by the human voice, and flashed almost instantaneously to distances which were limited, with regard to the former, by restrictions imposed by the globe. To Dr. Siemens had been assigned the task of introducing to their notice electric energy in a different aspect. Although still giving evidence of swiftness and precision, the effects he should dwell upon were no longer such as could be perceived only through the most delicate instruments human ingenuity could contrive, but were capable of rivalling the steam engine, compressed air, and the hydraulic accumulator, in the accomplishment of actual work.

In the early attempts at magneto-electric machines, it was shown that, so long as their effect depended upon the oxidation of zinc in a battery, no commercially useful results could have been anticipated. The thermo-battery, the discovery of Seebeck in 1882, was alluded to as a means of converting heat into electric energy in the most direct manner; but this conversion could not be an entire one, because the second law of thermo-dynamics, which prevented the realisation as mechanical force of more that 1-7th part of the heat energy produced in combustion under the boiler, applied equally to the thermo-electric battery, in which the heat, conducted from the hot points of juncture to the cold, constituted a formidable loss. The electromotive force of each thermo-electric element did not exceed 0·036 of a volt, and 1,800 elements were therefore necessary to work an incandescense lamp.

A most useful application of the thermo-electric battery for measuring radiant heat, the thermopile, was exhibited. By means of an ingenious modification of the electrical pyrometer, named the bolometer, valuable researches in measuring solar radiations had been made by Professor Langley.

Faraday's great discovery of magneto-induction was next noticed, and the original instrument by which he had elicited the first electric spark before the members of the Royal Institution in 1831 was shown in operation. It was proved that although the individual current produced by magneto-induction was exceedingly small and momentary in action, it was capable of unlimited multiplication by mechanical arrangements of a simple kind, and that by such multiplication the powerful effects of the dynamo machine of the present day were built up. One of the means for accomplishing such multiplication was the Siemens armature of 1856. Another step of importance was that involved in the Pacinotti ring, known in its practical application as the machine of Gramme. A third step, that of the self-exciting principle, was first communicated by Dr. Werner Siemens to the Berlin Academy, on the 17th January, 1867, and by the lecturer to the Royal Society on the 4th of the following month. This was read on the 14th of February, when the late Sir Charles Wheatstone also brought forward a paper embodying the same principle. The lecturer's machine, which was then exhibited, and which might be looked upon as the first of its kind, was shown in operation; it had done useful work for many years as a means of exciting steel magnets. A suggestion, contained in Sir Charles Wheatstone's Paper, that "a very remarkable increase of all the effects, accompanied by a diminution in the resistance of the machine, is observed when a cross wire is placed so as to divert a great portion of the current from the electro-magnet," had led the lecturer to an investigation read before the Royal Society on the 4th of March, 1880, in which it was shown that by augmenting the resistance upon the electro-magnets 100-fold, valuable effects could be realised, as illustrated graphically by means of a diagram. The most important of these results consisted in this, that the electromotive force produced in a "shunt-wound machine," as it was called, increased with the external resistance, whereby the great fluctuations formerly inseparable from electric-arc lighting could be obviated, and that, by the double means of exciting the electro-magnets, still greater uniformity of current was attainable.

The conditions upon which the working of a well-conceived dynamo machine must depend were next alluded to, and it was demonstrated that when losses by unnecessary wire-resistance, by Foucault-currents, and by induced currents in the rotating armature were avoided, as much as 90 per cent., or even more of the power communicated to the machine was realised in the form of electric energy, and that *vice versâ* the reconversion of electric into mechanical energy could be accomplished with similarly small loss. Thus, by means of two machines at a moderate distance apart, nearly 80 per cent. of the power imparted to the one machine could be again yielded in the mechanical form by the second, leaving out of consideration frictional losses, which latter need not be great, considering that a dynamo machine had only one moving part well balanced, and was acted upon along its entire circumference by propelling force. Jacobi had proved, many years ago, that the maximum efficiency of a magneto-electric engine was obtained when

$$\frac{e}{E} = \frac{w}{W} = \frac{1}{2}$$

which law had been frequently construed, by Verdet ("Théorie Mechanique de la Chaleur") and others, to mean that one-half was the maximum theoretical efficiency obtainable in electric transmission of power, and that one-half of the current must be necessarily wasted or turned into heat. The lecturer could never be reconciled to a law necessitating such a waste of energy, and had maintained, without disputing the accuracy of Jacobi's law, that it had reference really to the condition of maximum work accomplished with a given machine, whereas its efficiency must be governed by the equation

$$\frac{e}{E} = \frac{w}{W} = \text{nearly } 1.$$

From this it followed that the maximum yield was obtained when two dynamo-machines (of similar construction) rotated nearly at the same speed, but that under these conditions the amount of force transmitted was a minimum. Practically the best condition of working consisted in giving to the primary machine such proportions as to produce a current of the same magnitude, but of 50 per cent. greater electromotive force than the secondary; by adopting such an

Digitized by Google

arrangement, as much as 50 per cent. of the power imparted to the primary could be practically received from the secondary machine at a distance of several miles. Professor Silvanus Thompson, in his recent Cantor Lectures, had shown an ingenious graphical method of proving these important fundamental laws.

The possibility of transmitting power electrically was so obvious that suggestions to that effect had been frequently made since the days of Volta, by Ritchie, Jacobi, Henry, Page, Hjorth, and others; but it was only in recent years that such transmission had been rendered practically feasible.

Just six years ago, when delivering his presidential address to the Iron and Steel Institute, the lecturer had ventured to suggest that "time will probably reveal to us effectual means of carrying power to great distances, but I cannot refrain from alluding to one which is, in my opinion, worthy of consideration, namely, the electrical conductor. Suppose water-power to be employed to give motion to a dynamo-electrical machine, a very powerful electrical current will be the result, which may be carried to a great distance, through a large metallic conductor, and then be made to impart motion to electro-magnetic engines, to ignite the carbon points of electric lamps, or to effect the separation of metals from their combinations. A copper rod 3in. in diameter would be capable of transmitting 1,000 horse-power a distance of say 30 miles, an amount sufficient to supply one quarter of a million candle-power, which would suffice to illuminate a moderately-sized town." This suggestion had been much criticised at the time, when it was still thought that electricity was incapable of being massed so as to deal with many horse-power of effect, and the size of conductor he had proposed was also considered wholly inadequate. It would be interesting to test this early calculation by recent experience. Mr. Marcel Deprez had, it was well known, lately succeeded in transmitting as much as 3 h.-p. to a distance of 40 kilometers (25 miles) through a pair of ordinary telegraph wires of 4mm. diameter. The results as obtained had been carefully noted by Mr. Tresca, and had been communicated a fortnight ago to the French Academy of Sciences. Taking the relative conductivity of iron wire employed by Deprez, and the 3-inch rod proposed by the lecturer, the amount of power that could be transmitted through the latter would be about 4,000 horse-power. But Deprez had employed a motor-dynamo of 2,000 volts, and was contented with a yield of 32 per cent. only of the power imparted to the primary machine, whereas he had calculated at the time upon an electromotive force of 200 volts, and upon a return of at least 40 per cent. of the energy imparted.

In March, 1878, when delivering one of the science lectures at Glasgow, he said that a 2in. rod could be made to accomplish the object proposed, because he had by that time conceived the possibility of employing a current of at least 500 volts. Sir William Thomson had at once accepted these views, and with the conceptive ingenuity peculiar to himself, had gone far beyond him, in showing before the Parliamentary Electric Light Committee of 1879, that through a copper wire of only $\frac{1}{2}$ inch diameter, 21,000 horse-power might be conveyed to a distance of 300 miles with a current of an intensity of 80,000 volts. The time might come when such a current could be dealt with, having a striking distance of about 1·2 feet in air, but then, probably, a very practical law enunciated by Sir William Thomson would be infringed. This was to the effect that electricity was conveyed at the cheapest rate through a conductor, the cost of which was such that the annual interest upon the money expended equalled the annual expenditure for lost effect in the conductor in producing the power to be conveyed. It appeared that M. Deprez had not followed this law in making his recent installations.

Sir William Armstrong was probably first to take practical advantage of these suggestions in lighting his house at Cragside during night-time, and working his lathe and saw-bench during the day, by power transmitted through a wire from a waterfall nearly a mile distant from his mansion. The lecturer had also accomplished the several objects of pumping water, cutting wood, hay, and swedes, of lighting his house, and of carrying on experiments in electro-horticulture from a common centre of steam-power. The results had been most satisfactory; the whole of the management had been in the hands of a gardener and of labourers, who were without previous knowledge of electricity, and the only repairs that had been found necessary were one renewal of the commutators and an occasional change of metallic contact brushes.

An interesting application of electric transmission to cranes, by Dr. Hopkinson, was shown in operation.

Amongst the numerous other applications of the electrical transmission of power, that to electrical railways, first exhibited by Dr. Werner Siemens, at the Berlin Exhibition of 1879, had created more than ordinary public attention. In it the current produced by a dynamo-machine, fixed at a convenient station and driven by a steam-engine or other motor, was conveyed to a dynamo placed upon the moving car, through a central rail supported upon insulating blocks of wood, the two working-rails serving to convey the return current. The line was 900 yards long, of 2ft. gauge, and the moving car served its purpose of carrying twenty visitors through the Exhibition each trip. The success of this experiment soon led to the laying of the Lichterfelde line, in which both rails were placed upon insulating sleepers, so that the one served for the conveyance of the current from the power station to the moving car, and the other for completing the return circuit. This line had a gauge of 3ft. 3in., was 2,500 yards in length, and was worked by two dynamo machines, developing an aggregate current of 9,000 watts, equal to 12 horse-power. It had now been in constant operation since the 16th of May, 1881, and had never failed in accomplishing its daily traffic. A line $\frac{1}{2}$ a kilometer in length, but of 4ft. $8\frac{1}{2}$in. gauge, was established by the lecturer at Paris in connection with the Electric Exhibition in 1881. In this case two suspended conductors in the form of hollow tubes with a longitudinal slit were adopted, the contact being made by metallic bolts drawn through these slit tubes, and connected with the dynamo machine on the moving car by copper ropes passing through the roof. On this line 95,000 passengers were conveyed within the short period of seven weeks.

An electric tramway, six miles in length, had just been completed, connecting Portrush with Bush Mills, in the north of Ireland, in the installation of which the lecturer was aided by Mr. Traill, as engineer of the company, by Mr. Alexander Siemens, and by Dr. E. Hopkinson, representing his firm. In this instance the two rails, 3ft. apart, were not insulated from the ground, but were joined electrically by means of copper staples and formed the return circuit, the current being conveyed to the car through a tee iron placed upon short standards, and insulated by means of insulite caps. For the present the power was produced by a steam engine at Portrush, giving motion to a shunt-wound dynamo of 15,000 watts = 20 horse-power, but arrangements were in progress to utilise a waterfall of ample power near Bush Mills, by means of three turbines of 40 horse-power each, now in course of erection. The working-speed of this line was restricted by the Board of Trade to ten miles an hour, which was readily obtained, although the gradients of the line were decidedly unfavourable, including an incline of two miles in length at a gradient of 1 in 38. It was intended to extend the line six miles beyond Bush Mills, in order to join it at Dervock Station with the north of Ireland narrow-gauge railway system.

The electric system of propulsion was, in the lecturer's opinion, sufficiently advanced to assure practical success under suitable circumstances—such as for suburban tramways, elevated lines, and above all lines through tunnels, such as the Metropolitan and District Railways. The advantages were that the weight of the engine, so destructive of power and of the plant itself in starting and stopping, would be saved, and that perfect immunity from products of combustion would be insured. The limited experience at Lichterfelde, at Paris, and with another electric line of 765 yards in length, and 2ft. 2in. gauge, worked in connection with the Zaukerode Colliery since October, 1882, were extremely favourable to this mode of propulsion. The lecturer, how-

Digitized by Google

ever, did not advocate its prospective application in competition with the locomotive engine for main lines of railway. For tramways within populous districts, the insulated conductor involved a serious difficulty. It would be more advantageous under these circumstances to resort to secondary batteries, forming a store of electrical energy carried under the seats of the car itself, and working a dynamo machine connected with the moving wheels by means of belts and chains.

The secondary battery was the only available means of propelling vessels by electrical power, and considering that these batteries might be made to serve the purpose of keel ballast, their weight, which was still considerable, would not be objectionable. The secondary battery was not an entirely new conception. The hydrogen gas battery suggested by Sir Wm. Grove in 1841, and which was shown in operation, realised in the most perfect manner the conception of storage, only that the power obtained from it was exceedingly slight. The lecturer, in working upon Sir William Grove's conception, had twenty-five years ago constructed a battery of considerable power in substituting porous carbon for platinum, impregnating the same with a precipitate of lead peroxidised by a charging current. At that time little practical importance attached, however, to the subject, and even when Planté, in 1860, produced his secondary battery, composed of lead plates peroxidised by a charging current, little more than scientific curiosity was excited. It was only since the dynamo machine had become an accomplished fact that the importance of this mode of storing energy had become of practical importance, and great credit was due to Faure, to Sellon, and to Volckmar, for putting this valuable addition to practical science into available forms. A question of great interest in connection with the secondary battery had reference to its permanence. A fear had been expressed by many that local action would soon destroy the fabric of which it was composed, and that the active surfaces would become coated with sulphate of lead, preventing further action. It had, however, lately been proved in a paper read by Dr. Frankland before the Royal Society, corroborated by simultaneous investigations by Dr. Gladstone and Mr. Tribe, that the action of the secondary battery depended essentially upon the alternative composition and decomposition of sulphate of lead, which was, therefore, not an enemy, but the best friend to its continued action.

In conclusion, the lecturer referred to electric nomenclature, and to the means for measuring and recording the passage of electric energy. When he addressed the British Association at Southampton, he had ventured to suggest two electrical units additional to those established at the Electrical Congress in 1881, viz., the watt and the joule, in order to complete the chain of units connecting electrical with mechanical energy and with the unit-quantity of heat. He was glad to find that this suggestion had met with favourable reception, especially that of the watt, which was convenient for expressing in an intelligible manner the effective power of a dynamo machine, and for giving a precise idea of the number of lights or effective power to be realised by its current, as well as of the engine-power necessary to drive it; 746 watts represented one horse-power.

Finally, the Watt meter—an instrument recently developed by his firm—was shown in operation. This consisted simply of a coil of thick conductor suspended by a torsion wire, and opposed laterally to a fixed coil of wire of high resistance. The current to be measured flowed through both coils in parallel circuit, the one representing its quantity expressible in amperes, and the other its potential expressible in volts. Their joint attractive action expressed therefore volt-amperes or watts, which were read off on a scale of equal divisions.

The lecture was illustrated by experiments, and by numerous diagrams and tables of results. Measuring instruments by Professors Ayrton and Perry, by Mr. Edison, and by Mr. Boys were also exhibited.

The fourth lecture of this series will be delivered on **Thursday, the 5th of April, by Dr. J. Hopkinson, F.R.S., M. Inst. C.E., who will then deal with "Some Points in Electric Lighting."**

THE COUPLING UP OF DYNAMOS AND THE TRANSMISSION OF POWER.*

BY M. E. HOSPITALIER.

When transmission is effected by a machine placed at each end of a double line, the losses which are liable to occur, owing to imperfect insulation of the line, diminish the current which traverses the receiving machine, and, consequently, reduce at the same time the effective work per unit of time and the return.

FIG. 1.—Connections of the machines at Miesbach and Munich. G indicates the generator, R the receiver. The loss in the line diminishes the current in the receiver, and, consequently, the effective work and return. Bad insulation of the line is prejudicial.

FIG. 1.

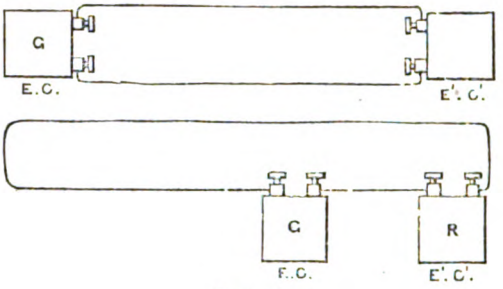


FIG. 2.

FIG. 2.—Connections of the dynamo machines in the workshops of the Northern (of France) Railway. G indicates generator, R receiver. The losses on the line do not influence the necessary equality between the current traversing the generator and that traversing the receiver. These losses diminish the resistance of the line, and increase the effective work. Bad insulation of the line is favourable.

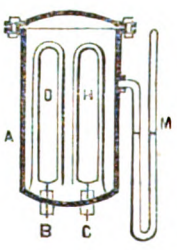
There is no comparison between two cases, 1, where the two machines are placed side by side, and connected together by a short and perfectly insulated wire; and, 2, by a telegraph line. In this case the more or less perfect insulation of the line has no influence on the always perfect equality existing between the current traversing the generator and that traversing the receiver. The result is that the return is independent of the insulation, and only depends on the relation between the E.M.F.'s, while the effective work increases as the insulation of the line diminishes.

A HIGH-PRESSURE ELECTRIC ACCUMULATOR OR SECONDARY BATTERY.†

BY FREDK. J. SMITH.

The modification of the gas-battery of Sir W. Grove which the author has devised is as follows:—

The gas-battery of Sir W. Grove, as usually made, when used as an accumulator, owing to the small quantity of gases that it holds, soon runs down when in use. In order to make its life longer, the author puts the gases under a high pressure. By this means a large quantity of gas can be stored in a suitably constructed instrument. The earliest form of battery, and this has been at work (*i.e.*, has been charged and discharged as an accumulator) for eighteen months, is shown in the cut. A is a strong lead vessel, well lined with rubber varnish, to prevent any solution of the lead being formed. O, H are platinised platinum cylinders, in inverted tubes held in their proper position by pieces of rubber. M is a manometer. The terminals B, C are brought through insulating stoppers. A 10-per-cent. mixture of sulphuric acid and water is used as the liquid. With this arrangement a pressure of seven atmospheres can be easily used; and thus the tubes, one of which has twice the capacity of the other, can contain sixty-four times the gas that they would do at the ordinary pressure. A second form has been made by Messrs. Becker and Co. for the



* Note on the influence exerted by the mode of coupling up dynamo-electric machines in experiments on the transmission of power to a distance, presented to the Academy of Sciences at Paris.

† Published in *Phil. Mag.* for March, 1883.

Digitized by Google

author. In this a U-shaped glass tube is used, the manometer being attached to the bend, and the sheets of platinum being fused into each leg. This form, although well suited for lecture purposes, will bear but a small pressure. A curious point observed, and one that is now being carefully worked out, is that the E.M.F. appears to vary much with the pressure.

The author has, in addition to the experiment described, charged small Faure or lead secondary batteries under pressure, the result being that the life of the battery is lengthened by being charged under pressure. Sufficient data have not as yet been collected concerning the variation of the E.M.F. under pressure, and the behaviour of the lead battery under pressure, to put into print. Should others experimentalise in the direction of high-pressure accumulators, a caution must be added with regard to the air-space left in the lead chamber, that quantity of air must be left which may be compressed, say, to seven atmospheres of pressure before the gas in O rises outside.

Oxygen produced by electrolytic action almost instantly acts on the best india-rubber tubing or varnish, causing splits and cracks to be formed in it. The chambers are now made of lead, to which a harder metal has been added.

THE PATENT BILL.

The Bill to amend the Patent Laws is now printed. Its chief points are as follow:—The Board of Trade is for the future to have the control over patents. The Bill revokes the Act appointing the Commissioners of Patents, and in their place appoints a "Controller-General of Patents, Designs, and Trade Marks," who is to act under the superintendence and direction of the Board of Trade. The method of applying for a patent has been altered. According to the proposed new method the applicant has to file with his application a specification describing his invention. This may either be "provisional" or "complete." Supposing it to be adopted, the provisional specification is to be referred by the controller to an examiner, who would report whether the invention is proper subject-matter for a patent, and whether it has been fairly described; also if the documents have been properly prepared. In case of an adverse report, the application may be refused, or the applicant may be required to amend his application; but there is in either case an appeal to the law officers. As soon as the application is accepted, the applicant receives provisional protection for twelve months, dating from his application. Nine months after the commencement of provisional protection he has to file a "complete specification," setting out more fully the nature of his invention, and this is examined in the same way as the provisional, to see that the two specifications agree, and that their claims are the same. In both specifications the "claims" must be distinctly stated. On the "acceptance" of the complete specification the fact is to be advertised, and the documents opened to public inspection. This acceptance must be complete within twelve months, or the application becomes void. For two months after the acceptance, the patent is liable to opposition before the law officers, who may refuse the grant. If there is no successful opposition, three months after acceptance the patent is sealed. If a complete specification is filed in the first instance with the application, the procedure is nearly similar. The fees are—on application, £1; on grant, £3; and the patent is good for four years. At the end of four years there is a fee of £50; at the end of eight, a fee of £100. The total duration of the patent is, as now, 14 years. The Bill also provides for the publication of an illustrated journal of patents, and the transference of the Patent Office Museum to the Science and Art Department. We shall refer to the Bill at greater length in a future issue. The subject is a very important one, and should be well discussed. The *Daily News* learns that when the Patents Bill comes before the House Mr. Anderson will, in some tangible form, raise the question of the expediency of greatly diminishing the cost of patents.

ELECTRIC LIGHTING AND LOCOMOTION.*

(CONCLUDED FROM PAGE 430.)

Now, suppose we have one of our motors adjusted to run without any winding on the field-magnets, and imagine we wind the field-magnets in such a direction that the motor would tend to turn in the opposite direction when a current passed round the coil wound round the field-magnets, what would happen? Why, if the magnetism induced in the field-magnets by the current flowing round it were stronger than the opposite magnetism induced in the iron by the armature, we should have the very curious and novel result that the direction of the motor could be reversed by simply short-circuiting with a thick piece of wire, the current flowing round the field-magnets, and this result we have practically attained, as I will now show you. [Experiment shown.] Allow the current to flow through the armature and field-magnets, and the motor runs one way; let it only flow through the armature alone, and the motion is instantaneously reversed. Merely pressing down the key then reverses the motion. Hitherto the much more complicated arrangement of reversing the electric connections between the armature and field-magnet has always been thought necessary to reverse the direction of motion of a motor.

We have in the preceding considered that the magnetism produced by the coil on the field-magnets was greater than that produced by the induction of the armature itself, and so determined the direction of motion. But suppose that is not the case, then what will happen? Why, then the current passing through the coil on the field-magnets will be resisting the motion, and so will be helped on. But that, as we saw before, is exactly the condition necessary for governing. The armature then and the iron of the field-magnets acts as a motor, while the armature and the coil wound round it act as a dynamo, and if the resistance of the coil, which we make of fine wire, and as a shunt to the armature, is of proper resistance, and the required speed of the motor is the critical speed of the dynamo, the governing of our motor may be made fairly perfect with only one circuit on it.

Hitherto we have been dealing with motors especially intended always to run at one speed whatever amount of work they might be doing. We next come to motors for electric tramcars, tricycles, &c., designed to run at any desired speed forwards or backwards.

I have spoken about the set of the brushes relatively to the field-magnet, and the set, or "lead" as it is technically called, is of great practical importance, since on the amount of lead depends which way the motor revolves or whether it revolves at all. Although the fact that the direction of rotation could be reversed by a sufficient change in the lead was well known, the importance of varying the lead in motors for different speeds appears to be little attended to, since it is impossible as a rule in motors, from their construction, to make small changes in the lead. In our motors, on the other hand, the flat brush-holder can be revolved forwards or backwards by hand through any angle, so that any lead forwards or backwards is obtainable, and in our larger motors, of which I have a sample here, the lead can be made anything we like simply by moving a handle, such as a locomotive engine-driver is accustomed to use for acting on the link-motion of his engine. In fact, by moving the handle forwards or backwards any speed, in either direction, is obtainable. We can, even when the motor is running, shift the brushes relatively to the field-magnet together with which they are rotating, and consequently with only one pair of brushes to give any lead forwards or backwards we desire. In other cases we alter the lead by means of a wheel and screw, and so get very easily a very accurate adjustment. A table of speeds can be engraved, showing the position the handle should be in for 500 revolutions a minute, or 700 revolutions a minute, &c.

On the last occasion I showed you photographs of all the principal electric railways, and we saw that in some cases the current went by an auxiliary insulated rail passed through the motor under the train, and came back by the rails. In other cases both the going and return wires were of the nature of stout overhead telegraph wires, and a running connection between the motor on the tramcar and these wires was kept up by two small jockeys, that were pulled along the telegraph wires by wires attached to the tramcar. In a third system, the going and return conductors were simply ordinary rails on which the train runs, the insulation produced by the rails merely resting on wooden sleepers having been found sufficient for a length of one or two miles. As you will see from the photographs that I now project on the screen, this last and simplest plan has been adopted for the Portrush Railway, near the Giant's Causeway, in Ireland. This electric railway, Mr. Traill (the chairman) has been so good as to write to me, "runs on a footpath, or trampath, by the side of

* Lecture II., delivered by Professor Ayrton, F.R.S., at the London Institution, March 15, 1883.

Digitized by Google

the road, which has been widened for the purpose from 24ft. to 27ft. The path is 7ft. wide, leaving 20ft. for the carriage-way. We first tried," he says, "sending the current by one rail, returning by the other rail, after passing across by the car, and for this purpose had laid the rails in asphalte with thick felt underneath, but we found that the leakage, especially in wet weather, was too great to justify us in continuing that kind of insulation for six miles." Now, this is exactly the result I predicted in my lectures on electric railways delivered last year, and in order to make the difficulty quite clear to you, I will show you the experiment I then showed to prove this. A portion of the going wire conveying the current working the motor is driving the circular saw, as you observe, wrapped round this bit of wood, and a portion of the return wire round this other piece of wood. As the two pieces of wood are dry there is very little leakage from the wire on the one to the wire on the other, although the wire wrapped round each is bare. If, however, without allowing these pieces of wood to touch one another, I immerse the ends of them in this vessel of water I shall produce the same effect as if a shower of rain fell at one end of the electric railway. Now, observe what happens, the motor immediately begins to go more slowly. Let me immerse them further, which will correspond with the rain becoming more general over the line, and the motor goes still more slowly, and now the motor stops altogether, so much of the current, in fact, leaking from the going to the return wire through the water that sufficient does not pass through the distant electro-motor to keep up its motion.

How, then, has this difficulty been overcome at the Giant's Causeway? Mr. Traill's letter tells us. He says:—"We have therefore placed a third rail of iron on wooden props close into the fence, so that a brush striking out from the car on a steel bar runs along the top of this third rail, which is about 15 inches from the ground." He goes on to say that this third rail is embedded in tar on the tops of the posts, and that when, in addition, pieces of the new insulating material ("insulite") are introduced between the rail and the wooden posts they expect the insulation will be perfect. He adds:—"At present we can run for over two miles on the road up and down hill gradients as great as 1 in 35. We took six tons up that incline the other day. We are about to erect turbines at the waterfall above Bushmills, which will give us from 60 to 100 horse-power, and will generate the current there about half a mile from our main line at Bushmills. We have powers by our Act of Parliament to construct a railway from Bushmills to Dervock (inland about seven miles) almost at right angles to the line of tramway on the sea coast. As the waterfall is near the junction of railway and tramway we intend to use it for the railway as well, as the works will do for both. We are limited by an Act to 10 miles an hour on the tramway, but will have no difficulty in going to 20 or 25 miles an hour on the railway, which has also the advantage of being level the entire way."

But although they have succeeded at Portrush in overcoming the difficulty of leakage by using this third insulated rail, resting on posts 15in. above the ground, such a system presents, you will easily see, great inconveniences for ordinary railways, since at every crossing there would be this raised rail in the way of the trains, and an even greater objection is the risk that it introduces, that any one can, from carelessness or malice, by resting, say, a crowbar against this raised insulated rail, send all the electricity to the earth and so cut off all electric power from all the trains either in front or behind.

On the other hand, the plan of using stout telegraph wires, with running jockeys to keep up continuous electric connection between these wires and the moving train, would present great mechanical difficulties if the trains were going at 60 miles an hour.

What, then, do we propose? Professor Perry's and my plan is this: we electrically subdivide the rubbed rail into a number of sections all fairly, but by no means perfectly, insulated from the ground. We do not apply our electricity directly to this rubbed rail, but, instead, to a well-insulated conductor, which may be buried underground or may be insulated by resting like a telegraph line on insulators or posts, and we arrange that whenever a train enters on to any section, it automatically makes an electric connection between that section of the rubbed rail and the well-insulated conductor which supplies the power, and at the same time automatically cuts off the electric power from the section the train has just left, and in this way we confine the leakage of electricity to that section on which the train is at any particular time, and so reduce the leakage and waste of power on the longest electric railway to less than it is at present on the shortest line constructed on the Berlin plan.

But not only does a train on entering any section automatically turn on the electric power to that section, and cut it off from the one just left, but it accomplishes something more; it blocks absolutely the section just left. Let us take an example:—Suppose a train is passing from section A to section B, then not only is the power automatically turned on to section B and cut off from section A, but no following train entering on section A can receive power and move on as long as the train in front is on section B. It is not until the preceding train has passed into section C that the following train can proceed along section A. And, in addition, whenever a train is approaching too near a train in front, and in consequence finds itself deprived of driving power, it is automatically, by a special plan we have contrived automatically, powerfully braked.

Whenever, then, a train—it may be even a runaway engine—enters on a blocked section, not only is all motive power withdrawn from it, but it is in addition automatically powerfully braked quite independent of the action of signalman, guard, or engine-driver, even if the latter two be present, which, bear in mind, is not at all necessary with our electric railway. No fog nor colour blindness, nor different codes of signals on different lines, nor mistakes arising from the exhausted, nervous condition of overworked signalmen can with our system produce a collision. The English system of blocking means merely giving an order to stop, but whether this is understood or intelligently carried out is only settled by the happening or non-happening of a subsequent collision. Our absolute automatic block acts as if the steam were automatically shut off, and the brake put on whenever the train is running into danger; nay, it does more than this, it acts as if the fires were put out, and all the coal taken away, since it is quite out of the power of the engine-driver, if there be one, to re-start the train until the one in front is at a safe distance ahead.

At present much household work is done by hand, simply because there are no easily-worked machines for doing it. The old knife-board has given way to the rotary knife-cleaner, but even that requires a certain amount of grinding to give the knives a polish, so that for large establishments a knife-cleaner boy is still necessary. The blacking of boots, the blacking of grates, the cleaning of doorsteps, &c., are all done in a most laborious way by hand. (I might almost say the operation seems not to be confined to hand, judging from the generally smutty appearance of Sarah Anne after the process.) Now, there can be no doubt that very shortly electricity will be supplied, as gas is now supplied, to houses for lighting purposes, and when this has been accomplished, the same wires that convey the electricity for lighting during the night will be employed in the day to convey the power to work electric-motors to turn rotary knife-cleaners, to turn a wheel for the blacking of boots, and a small motor carrying a brush like the one in my hand will simply be passed by the servant all over the grate for the purpose of giving it a good black polish. The black-lead brush will then be taken off, and replaced by the blacking brush for the boots, and later on in the day a rotary flannel will officiate for the door-steps.

The high price of land in towns necessitates gas works being in the suburbs, so in the future the electric works must be in the country, and probably farther away from the towns than even gas works are at the present time, because not only will great economy be so attainable, but the town will be freed from the smoke of the engines to drive the dynamo machines or producers of electric current, and by that time we shall have begun to realise that a smoky atmosphere is a poisonous atmosphere; further, if our dynamos are far away in the country advantage can also be taken of natural sources of water power.

The transmission, then, of power by electricity is not only a problem which must be solved, but is one which calls for immediate solution.

For the economic electric transport of power we must produce, as I have explained, a great difference of potentials by a dynamo at the place where the power is obtainable—in the suburbs where, for example, is the steam engine or water wheel—and employ some mechanism which can be worked by this great difference of potentials at the place where the power is to be utilised—that is, in the town. There is no difficulty in arranging a dynamo wound with fine wire, or a set of dynamos in series with one another, to produce any difference of potentials required; but there is a far greater difficulty in using this great difference of potentials at the town end of the line. If lamps and motors of the present construction are used they would have to be put in series, but in that case if the current is stopped passing through one it will be stopped passing through all. This difficulty can to a great extent be avoided by using "cut-outs," as I described to you in my last lecture. At the same time nobody would be perfectly satisfied that his supply of electric power should depend on the good working of all the electric apparatus in the same street, much less that it should depend on the good working of all the electric apparatus in the same town. We are content that our supply of gas or water should depend on the good working of the gas or

Digitized by Google

water works, but we could not tolerate the possibility of Betsy Jane, in Moorgate-street, from some carelessness or other, being able to cut off our supply at the London Institution. That Jack Frost should stop our supply is bad enough, but Betsy Jane—no!

What, then, are we to do? High difference of potential we must use, and we cannot work the lamps and motors in parallel unless they have a resistance of tens of thousands of ohms, in fact, are of a totally different description from the lamps and motors of the present day. The solution was first suggested by Sir William Thomson in 1881, and, I am happy to say, will very shortly be carried out in Paris by Professor Perry and myself, under the auspices of the French Electrical Storage Company. It is to use the small current and great difference of potentials to charge a very large number of accumulators, in series, in the town, and to discharge them in sets, as shown in the figure, each set supplying the energy for one street, or, possibly, for one district. Of course, the going and return wires between the dynamo and accumulators must be separately insulated, and put so far apart that there is no fear of a man or an animal accidentally touching both. If, in addition, it is feared that although this precaution is taken still somebody may touch a leading wire, say A, coming from somewhere near one end of the accumulators, while another person may accidently touch a leading wire, B, coming from somewhere near the other end of the accumulators, and so both receive a fatal shock, this may be also entirely avoided by electrically disconnecting the various sets of accumulators from one another, and from the main charging wires coming from the dynamo before they are connected respectively to the local leads in the streets for being discharged.

Suppose a thousand accumulators were thus employed, and a charging current of 33 amperes were used. To balance the electromotive force of the accumulators about 2,100 volts would be required. If the resistance of each cell were 0·005 of an ohm during charging, then 165 volts difference of potentials would be required to send a current of 33 amperes through this resistance, or a total difference of potentials of 2,265 volts would have to be maintained at the terminals of the accumulators. Hence about 100 horse-power would be put into them.

The next question that arises is, what size of conducting wire is it proper to use to convey a current of 33 amperes? If the conductor is thin it will certainly not cost much to erect; but, on the other hand, the resistance to the passage of the current will be great, and much of the power will be wasted in the heating of the wire. On the contrary, if the conductor is very thick, there will be practically no waste of power by the heating of the wire, but the capital sunk in erecting it will be excessive. It is clear, then, that there is some thickness which gives us the best results, and Sir William Thomson has worked out this problem for us, and has shown us that the thickness of the conductor proper to be used for any particular current does not depend at all on the length of the conductor, but depends first on the strength of current passing through the conductor; second, on the cost of copper per ton; and third, on the market value of one horse-power supplied for a year. Assuming that good conductivity copper costs £70 per ton, and that the market value of a horse-power is £10 per annum, the proper diameter to give to a conductor conveying a current of 33 amperes comes out to be 32-100ths of an inch, or a trifle over 3-10ths, on the assumption that the current passes for 12 hours out of every 24.

In order to send this 33 amperes through ten miles of going and ten miles of return copper wire, 32-100ths of an inch in diameter, as well as through the 1,000 accumulators, will necessitate the dynamo producing a difference of potentials of 2,654 volts. Under these circumstances calculation shows that about 17 horse-power would be lost in heating the line wires, about seven horse-power in charging the accumulators, and about a further 25 horse-power in the dynamo itself, which is in the country. 142 horse-power must, therefore, be given by the steam engine or water wheel to this dynamo.

We come to the conclusion, then, that if 142 horse power is given by the engine to the dynamo, 117 is given up by the dynamo to the wires; 100 is given up by the wires to the accumulators in the town, and 93 is stored up in the accumulators for future use, the total horse-power usefully stored up in the accumulators being in this particular case about 65 per cent. of that given to the dynamo by the engine.

The world thinks of a current of electricity as it thinks of a current of water. Now, there is this very essential difference between the supply of electricity to houses and the supply of gas or water to houses. When gas is supplied, you have only to deal with the *quantity* supplied; you are not going to use the pressure of the gas to do work, even if the gas is to be used in a gas engine. It is only the burning of the gas that you are interested in. You are really dealing, therefore, with *quantity* of gas. Similarly when water is supplied, nobody cares very much about the pressure so long as it is sufficiently high to reach the top story of his house. But if the pressure is 700lb. per square inch, as used by Sir William Armstrong, or 1,500lb. per square inch, as used by Mr. Tweddell, then the pressure becomes a very serious matter. Ordinary water is mainly used for drinking and washing purposes, and although this high pressure of water could also be used for drinking and washing, nobody but a millionaire would think of such extravagance; for it is not merely water, but water at a pressure of 1,500lb. per square inch that is supplied, and every cubic foot of water received per minute at that pressure by the consumer means 6 horse-power. In that case the pressure is all important, and for measurement you must take the quantity of water multiplied py the pressure. And although mere quantity of water may be important for washing purposes, we know of no purpose requiring mere quantity of electricity; it is needed as a source of energy to drive a motor, or to produce light, and the *amount of energy*, not the *quantity of electricity*, is what must be measured.

In any proper commercial recording meter for electricity a record must be kept, therefore, of two things—the quantity of electricity and the pressure which it is supplied at. Now, the electric meter or "ergmeter," as we call it, designed by Prof. Perry and myself for this purpose, is hanging up here. It consists of a fairly good pendulum clock, possessing a seconds hand. The pendulum bob has been taken off, and a coil of wire of about 1,000 ohms resistance substituted in place of it. Fixed on the case of the clock, near the fine wire coil, there is a coil of thick wire through which the main current passes.

The current passing through the pendulum bob depends on the difference of electric pressure at the main where it enters the house and leaves the house, whereas the current passing through the thick wire coil is the total current works the lamps and motors. Now, the electric power being supplied to the house depends on the strength of one of these currents multiplied by by strength of the other, and it can be proved mathematically as well as, of course, experimentally, that the total quantity of electric energy supplied to the house during any time, whether sometimes in the form of high pressure and small current, or sometimes in the form of small pressure and large current, is exactly proportional to the loss of the clock in that time. The number of minutes of slowness is the measure of electric energy supplied to the house, and is what should be charged for. An ordinary clock may doubtless lose a few minutes in a week, but we of course make the loss which we want to observe much greater than this. An ordinary clock wants winding up every week, but this of course is easily got over, and if experience in the future shows that the observations of the ergmeter by the electric inspector are only taken at distant periods that the clock would lose more than twelve hours between his visits, due to its measuring the electric energy supplied to the house in the meantime, then a hand will be added which takes, if we like, a day to make one complete revolution.

In the legislation which has recently taken place in connection with the commercial supply of electricity, a mistaken notion has grown up that the *quantity* of electricity is what should be recorded, and not electric energy. Now, not only is this bad in that it prevents an estimate being easily formed of the relative prices charged by the different companies for the supply of electricity, since the different companies use normally very different electric pressure, but even the most perfect system of governing dynamos, such as I described to you last time, or of laying the wires under the streets, such as has been suggested by Mr. Edison, will not enable the electric pressure at any house to be kept absolutely constant during the day, even if the electric pressure at the mains where they leave the dynamo is kept absolutely constant.

That is to say, with any system that has been hitherto suggested it is physically impossible, and, therefore, I need hardly say, cannot be made possible by legislation, to keep the pressure at a considerable distance from the producing station absolutely independent of the number of intermediate houses that are consuming electric power. In my opinion, then, we should not tolerate either the recording of, or the paying for the *quantity* of electricity supplied, but we must record and pay simply for electric power.

Two years ago the storage of electric energy in black boxes, and their power taken out of them by Sir Wm. Thomson, may have passed before the minds of the public as one of those mere seven days' wonders which in these latter times have become so common. But to the scientific man, who could foresee the possibilities connected with the electrical storage of power, these experiments of Sir Wm. Thomson were of pre-eminent importance.

The two latest employments of electricity stored in Faure-Sellon-Volckmar accumulators are in the boat "Electricity," which many may have seen running last Saturday at Kew, and a photograph of which I now project on the screen, and the electric tricycle of Professor Perry and myself. In the tricycle no work is done by the rider, but little black boxes carried on the base-board contain the stored electric energy pretty much in the same way as a horse's body contains its breakfast of oats and hay, with the difference that with the accumulator it is the receptacle which has weight, so that neither in receiving its feed in the morning or discharging its power during the day does the accumulator gain or lose in its weight. By means of a tap the rider can turn on more or less electricity and go faster or slower. The faster he is going the less is the waste of the electricity, although, of course, the consumption of power is greater than when going slowly—that is to say, the faster the tricycle goes the more efficient is the whole arrangement. On the other hand, when the electric supply tap is turned off and the tricycle is at rest the waste in the accumulators is not large, and the tricycle stands for days ready for immediate use without any waste analogous with an unused horse "eating his head off."

But although the electric tricycle ceases using up its last supply of electricity when it stops, and requires no feeding while motionless, still it must be fed periodically if used regularly. But very shortly I expect to see the tricyclist dismounting at his inn—with the sign, perhaps, of the "Faraday"—having the certainty that in the morning he will find his accumulators fully charged up with the electric machine of the inn, also used for lighting and agricultural purposes. I feel also sure that when this is the case the charge in his bill for the electric feed will be one of the smallest items entered.

Let us now adjourn to the library to see our electrically-lighted and driven tricycle in actual operation, and which the size of this lecture hall, large though it be, prevents my showing you here, and, that you may judge of the tricycle's power, I may mention that with it we have actually run a measured mile in 8¾ minutes, when the tricycle was carrying a man of average weight and the necessary supply of electric accumulators to propel it for about two hours.

What stored electricity can do the accumulators before you, kindly lent by the Electrical Power Storage Company, have shown. What the future of electrical locomotion may be who can say? The subject is yet young, very young. Improvements on what I have talked about to you to-night will no doubt be made. Perhaps Professor Perry and myself already see how some progress may be made. But at all events, I trust I have shown you that electric locomotion is already so far developed as to be a real commercial subject of discussion.

ELECTRIC LIGHTING AND THE TRANSMISSION OF POWER.

On Saturday evening, the 17th inst., Mr. Reckenzaun, C.E., delivered a lecture upon the above subjects at the Working Men's College, Great Ormond-street. Sir Daniel Cooper presided, and introduced the lecturer, than whom he said no one was more able to explain the subject upon which he was about to speak. After some introductory remarks, the lecturer said that most of the great discoveries and inventions had had difficulties to overcome, and if there were any prejudice against the electric light, it only proved the general rule. Gas had been considered an expensive luxury when first introduced, because people in those days had been accustomed to darkness. As, however, we became accustomed to more light, and better light, it would be a source of wonder why we had not adopted the better light sooner. That electric light was a nearer approximation to the solar rays than any other artificial light was proved by the fact that it would ripen fruit and act upon sensitised photographic plates. Beyond this the electric arc did not evolve carbonic acid gas, and was, therefore, conducive to health as well as to comfort. Gas was sold by measure; we paid for it at a certain rate per 1,000 cubic feet, and careful people expected to get a definite amount of light out of a certain quantity of gas. The intensity of gaslight was measured by candles, and a gas burner of fourteen candle-power should be equal to fourteen candles, *i.e.*, fourteen standard sperm candles burning 120 grains of sperm per hour. The electric light was also measured by candles, and the simplest means of arriving at that measurement was by the use of the photometer. This process consisted of throwing shadows upon a screen with different lights, the standard light being a candle, the relative value of the other light being determined by its distance from the screen when the two shadows were equal in intensity. The lecturer then described other means of measuring electricity, and defined the units known as volts, amperes, ohms, and watts. The most convenient forms of instruments for measuring electromotive force and currents were, he contended, Messrs. Ayrton and Perry's ammeter and voltmeter, in which the deflections of a needle indicated on the scale what electricity was doing in a circuit. Turning to the question of electric lighting, he referred to the old-fashioned methods of generating electricity by means of the Bunsen and other batteries, and said that the inconveniences attending the manipulation of powerful galvanic batteries, such as the labour of charging them, the evolution of unhealthy gases, and the great expense due to the consumption of materials, had prevented the adoption of electric light under those conditions. It was certain, without the development of Faraday's grand discovery of magneto induction, that it would never have become a commercial success. Referring to the heat of the electric arc, the lecturer said it was the most intense of all the artificial sources of heat. Dr. Siemens had recently constructed a small electrical furnace, in which steel or iron could be fused in a few minutes. The carbon rods of the arc were consumed slowly in the atmosphere, and it was a remarkable fact that the carbon connected to the positive pole of a battery or dynamo machine burned away twice as fast as that connected to the negative pole. As the carbons burnt away the electric arc became gradually longer until the light was extinct. In order to render the light continuous, various automatic regulators had been devised, that applied to the Brush lamp being one of the most perfect, enabling, as it did, the single carbon lamp to burn for eight hours, and the double lamp for sixteen consecutive hours without attention. The Weston lamp, which regulated itself according to the strength of the current, had given very satisfactory results, and produced a steady white light. The Pilsen-Joel lamps had also found favour in this country, and were sometimes fed by accumulators. The lecturer then dealt with the incandescent lamps of Swan, Edison, Maxim, Lane-Fox, and others, and displayed specimens of each in action. The generation of electricity was then dealt with, and, after describing the principle of magneto electric induction, he said that the stronger the pole of a magnet was the greater would be the number of lines of force which radiated from its poles, and the stronger would be the induced currents in the moving coil of a magnet. Also the more rapid the motion the stronger would be the momentary current induced in the coil, and the greater the number of turns in the coil the stronger would be the total current induced by it in moving in the magnetic field. Those points were of vital importance in the action of dynamo-electric generators. In a dynamo machine a number of coils were generally arranged so as to form a ring, which revolved between the poles of a magnet. The ring was known as the armature, and it was necessary to combine in one armature a large number of coils, in order to procure a steady and continuous current. Ring armatures were employed in the Brush and other generators of recent date, as well as those of Gramme. Drum armatures were used for the Siemens and Edison machines, and consisted of coils of wire wound lengthways over a drum instead of round a ring, the wire being carried along the drum parallel to the axis across the end and back along the drum on the opposite side. As fast as the current was generated in the bobbins it was drawn off by the commutator and the contact brushes. The commutators consisted of as many pieces of insulated metal as there were bobbins arranged round the shaft of the machine, the ends of the bobbin wire being soldered on to them. By means of the electric current we were enabled to transmit power to great distances. Streams of water hitherto run to waste, because of the distance from manufacturing towns, would in the future be utilised, and the force would be transported by conductors to do work in the mill or on the farm, to grind the corn, till the land, and light the streets and houses. The Niagara falls alone, it had been calculated, contained a force of 15,000,000 of horse-power. The River Severn, they had been told by Professor Silvanus Thompson, would yield sufficient power to work all the cotton spindles in the United Kingdom, light every city in the country, and yet leave a large margin of waste. One of the first practical applications of the electric transmission of power to a distance had been made at the Vienna Exhibition in 1873, where a dynamo actuated by a gas engine had had its current transmitted through a wire half a mile long to a Gramme machine, which drove a centrifugal pump. More recently, at the Munich Exhibition, Marcel Deprez had transmitted a fraction of a horse-power to a distance of 57 kilometres along an iron telegraph wire. In France experiments had been made with a view of employing ploughs and other agricultural machines worked by electro-motors.

The lecturer then explained the principle of the electric railway and the storage of force for motive power by means of accumulators, and said that Messrs. Sellon and Volckmar had improved upon the accumulators of M. Faure to such a degree that, while a Faure battery weighing 80lb. could store the enormous force of about one million and a half foot pounds, the Sellon-Volckmar cell of the same weight was capable of holding nearly double that energy.

In conclusion the lecturer said that the question relating to the transmission of power to distances gained daily in importance. Thousands of tons of coal were sent from England to almost every quarter of the globe to be used for the production of steam power and artificial light, the cost of transport amounting, in many cases, to more than the original expense of raising it from the bowels of the earth. It had been calculated that the total steam power used in the world amounted to 80,000,000 horse-power, exclusive of steamships, and that the cost of producing that enormous power amounted annually to about twelve hundred millions of pounds sterling. Hence a saving of only ten per cent. in the consumption of fuel would add £120,000,000 to the total riches of the globe every year. The inventors who had done so much to reduce the consumption of coal in the steam engine had contributed, probably, more to the material wealth of mankind than any other benefactors. The processes of still further economising fuel were becoming more difficult, and it behoved us to consider whether the supply would not be exhausted in a few years, and even if it would be for ever available, it was the duty of the scientist to seek every means of lessening its consumption, or to substitute a force which might still further benefit mankind.

On the motion of Sir D. Cooper a vote of thanks was unanimously accorded to the lecturer, who had illustrated his address by numerous experiments and diagrams.

The whole of the electric power used for the purposes of the lecture was supplied from Faure-Sellon-Volckmar accumulators.

River Plate Telephone and Electric Light Company.—At an extraordinary general meeting of this Company, held on Tuesday, the following board was elected:—Colonel Gouraud, chairman; Patrick Carnegy, Esq., C.I.E.; W. Edward Fauvel Powers, Esq.; Hon. Howard Spensley, and Sir Julius Vogel, K.C.M.G.

Digitized by Google

ELECTRICAL POWER STORAGE COMPANY (LIMITED)

The annual general meeting of this Company was held on the 21st inst., at the City Terminus Hotel, under the presidency of Sir Daniel Cooper, Bart., K.C.M.G.

The SECRETARY (Mr. Holland Dell) read the notice convening the meeting, and the minutes of the last meeting, which were confirmed.

The CHAIRMAN, in moving the adoption of the report, said, in the course of a detailed speech on the position and prospects of the Company, that it was really the first occasion on which the directors had had the pleasure of meeting the shareholders after an interval sufficient to give evidence of the prospects of the Company. These he was sure they would agree with him, when they had heard the plain statement he proposed to give them, were of an assuring character. After referring to the formation of the Company, in March, 1882, and to their entire acquisition of the Faure patents for the world, he explained that at the time of the original negotiations with the owners of the Faure patents they were under certain engagements as to the sale of their American and Belgian rights. Under these circumstances they were obliged to adopt these engagements with any benefits attaching to them. One, the smaller one, was the sale as regarded Belgium for £20,000 in shares of the Société d'Electricité Belge et Hollandaise. They attached very little value to these shares at the present moment, because the Belgian Company only possessed the rights for the Faure patents, and none for the Sellon-Volckmar, which was the only valuable one commercially. What they would do in the future with the Belgian Company he could not, at present, say. The other engagement was of quite a different character, greater in magnitude, and capable of giving immense returns to this Company. After giving the details of this contract, and the subsequent action taken in America with respect to them, he stated that in May last they sold to the Indian and Oriental Electrical Storage and Works Company the Sellon-Volckmar patents and rights for India and its dependencies, the Straits Settlements, Egypt, and Malta, for £25,000 in cash, £25,000 in royalties, and £50,000 in cash or fully-paid shares, at the option of the directors of the Indian Company. Subsequently, when this Company acquired the Faure patents, they transferred these for their territories to the Indian Company, on condition of their paying the royalties of £25,000 within nine months from that date, and at once issuing to the Company £25,000 in fully-paid shares. This left £25,000, which they had still to pay this Company in cash or shares at their option, and instalments of royalty £15,000. Of this, £5,000 was now paid, leaving that day £10,000 still to come. Having referred to the Australasian patents he continued: The last negotiation I have to tell you of, and I must apologise for the time I am taking up, is that with France, which has been a source of great labour and anxiety to your directors. Finally, we have provisionally sold the French patents to the French Electrical Power Storage Company for £300,000, payable thus:—£72,000 in our own shares, which we propose to accept surrenders of, £70,000 of which we may practically annihilate, so as to leave our capital at £530,000; £3,000 we receive in cash; and the French Company is to pay us by way of royalties at least £25,000 by January 1, 1884, and by January 1 of each succeeding year for five years £40,000, until the whole £300,000 is completed. The provisions of the contract are that until the full payment of £300,000 is made to us we do not part with the patents; that whatever licenses or sub-sales take place, the benefit accrues to us and payments are to be made to us; and that, if in any year, until the whole purchase money is paid, default is made in payment of the amount stipulated, the French Company lose absolutely and altogether all right whatever in the patents, which will remain to us free from any claim whatever of the French Company. I think you will agree with me that we ought to congratulate ourselves upon such a contract, which brings about a present reduction of nearly 12 per cent. of our capital, and secures by future payments, one half of our capital. Negotiations are pending with regard to other countries. He then spoke at length as to the purely manufacturing portion of the business, and expressed his belief that in that respect his report would be equally satisfactory to them. Their intention was to work on steadily as manufacturers. For this purpose they had looked out for eligible premises, and were fortunate in securing a lease for 60 years of their works at Millwall. It was only on the 1st January that they announced their willingness to sell to the public. He then referred in detail to the various items in the balance-sheet, observing as to the stocks in hand that the meaning of the words "present cost prices" was that day by day they were learning their business better, and producing their goods cheaper, but when dealing with their stocks in hand, they had taken as their value only that which they would cost them to make now with their improved facilities and their greater experience. The last item—the balance of profit and loss account—they proposed to write off in full. After going through the profit and loss account, he continued: The nominal balance of profit shown is £346,930, which is in appearance an enormous amount, but, as I have already explained, it really consists mainly of fully paid shares, royalties, and deferred cash payments. Under these circumstances we do not propose to make any distribution, or to declare any dividend, but we do what is the same, or in my opinion far better in an undertaking such as ours, we place ourselves in a position, if you later on pass the resolution to be submitted to you, of virtually reducing our capital by the large sum of £70,000. To demonstrate the usefulness of accumulators for motive power as well as for lighting, we sometime ago purchased a steam launch, took out the steam apparatus, and fitted it with accumulators and a motor, and that little boat has run at all times and in all weathers on the Thames for four months. She has carried many distinguished persons, and none of them but have expressed their satisfaction. I hear that she was figuring at the University Boat Race and showed in good form. Another experiment in motive power was an electrical tramcar; with regard to that car we have still to overcome difficulties of an engineering and mechanical character, but I can state myself, positively, that our accumulators were in no way responsible for any deficiencies at the first trial. They worked, and still work, most admirably for the purpose, and we have found a solution, we believe, to the other difficulties which we met with, and we shall in a few weeks, if not before, be in a position to run our car on the road—letting it take its chance with the others. One last word with regard to the places where our accumulators are finding their way. We have among our customers nearly all the electric light systems. We have supplied them for the Law Courts, to the Swan Company and Messrs. Crompton; we have sent them for use by Siemens Brothers on board an Atlantic steamer; we have supplied them to Brush Companies for some important installations; we have ourselves installed electric light at the offices of the P. and O. Company; we have fitted up the Grand Hotel with 400 lights, which will be running in a few days. The Pullman train to Brighton is lit off our accumulators, and, as as a proof of their successful working, I mention that last week the railway company ordered another set. Perhaps one of the most satisfactory orders we have received was from the Science and Art Department at South Kensington, where a battery had been working under the most severe test for about three months, and only a few days ago we received an official order, not only for the battery they had had in use, but for another larger one. There are also a number of small installations and private installations, which we look to to induce many others to come forward. On the Continent we are supplying the Anglo-Austrian Company with an accumulator of 700 e.h.-p., for the illumination of the Opera House at Vienna. The orders we have received up to date for accumulators, including those required for installations, amount to 6,400 e.h.-p., equal to about £20,000, a fact which, seeing the few weeks we have been selling the accumulators publicly, I regard as most promising. I think these give evidence of what we may look forward to as a universal and extensive employment of our accumulator.

The DEPUTY-CHAIRMAN (Mr. J. S. Sellon), in seconding the motion, thought the position of the Company must be considered as very satisfactory, but if they would allow him to express an opinion he would venture to say that what was now being accomplished was but an earnest on a very limited scale of what might confidently be anticipated when once the immense importance of the accumulator system, and its indispensability under very many conditions of electrical work, was fully realised. Notwithstanding what had been said in some quarters, he made bold to say that a day would come when the most sceptical would be constrained to admit that no business of modern times was likely to excel in importance, in its gigantic application, that which they were now carrying out—namely, of providing a means for electrical storage, and the safe control and the efficient utilisation of this great power. With regard to the batteries which had now, practically only within the past few weeks, made their *début* before the public, the Company with which they were now associated launched them forth, not as having attained that absolute perfection in detail which could only be brought about by long experience, but as having attained a degree of perfection which warranted their being issued to the public. After referring to the energy with which the affairs of the Company had been conducted, and speaking especially of the perseverance of Mr. Volckmar, he expressed his belief that many of them would live to see electrical energy going ahead of every other known power. He did not think it was possible for them to realise in the near future the working of mills, of railways, and of steamers by the aid of this power—of the boon it would be, for instance, if the public could travel in comfort, being lighted, warmed, and moved by this power on the underground railways. That would certainly be a remedy for the question which was agitating the public as to the offensive ventilators on the Embankment. They all knew that one of the great difficulties in dealing with this power had been its storage in a form which could be available at any moment, day or night. That difficulty had now been overcome. They also knew the difficulty that had existed as to its working with the greatest possible economy by means of natural forces. They all knew what a prolific source of power we had in water. This was a matter which was now receiving more attention than at any previous time. Now that electrical energy could be stored and used when wanted, it must be of the greatest importance to the whole community. He thought, for his own part, that the practical application of electrical accumulators was virtually unlimited, and step by step he believed that its utilisation would be secured. The chairman had referred to the lighting of the Pullman car on the Brighton Railway, and it might be interesting to them to know that whereas a year, in fact, six months, ago, it took seventy of the ordinary accumulators of the original pattern to light eighteen lamps, it took only thirty of their present pattern to light forty lamps, and their total weight was less than half that of the original battery. That would show them the great improvements which had been made in details, and he was sure that they would be continued, while carried on in such hands as those who were already engaged on the work.

The CHAIRMAN, in answer to Mr. Schiff, stated that they had heard a good deal about the Brush accumulator patent, and there had been some speculation concerning it. They had, however, consulted some of the best authorities, and they thought there was very little in it. If an attempt were made to work it here this Company would immediately step in and take steps to stop it. As far as they know, there was really no accumulator whatever, except their own, that was of any commercial value, and, as far as they could ascertain, other accumulators, which were talked about, were worthless commercially. He afterwards, in reply to Mr. Trench, read over the names of the directors, and stated that their meaning of the word royalty was this—there was a great deal of lead used in the accumulators, and they had bargained that those who made the accumulators should pay the Company £20 a ton. In the French agreement the amount taken was a *minimum*, and if they did not use the quantity of lead, they must, nevertheless, pay this Company the money. If the French company used the *minimum*, or below it, they would pay the Company £40,000 a year; if they used £10,000 worth of lead more, that surplus would go against the next year.

Mr. T. SUTHERLAND (Chairman of the Peninsular and Oriental Steam Navigation Company) testified to the successful working of the Company's accumulators at the offices of the Peninsular and Oriental Company, observing that they had been under his close personal observation during the last three months. The installation consisted of a small gas engine, and a small dynamo machine of Edison's and fifty accumulators, while the lighting circuits were, he believed, three or four in number. That was altogether about 280 incandescent lamps, of which the smallest was of 20 candle-power, while a considerable number were of even 40. The dynamo, which was a very efficient one, was sufficient to light only 60 of the lamps. They had tried several times to use the light direct from the dynamo, and although the lighting of the 60 lamps was so far satisfactory,

Digitized by Google

it was accompanied by that somewhat distressing flickering which he thought was almost universally experienced in lighting taken from a dynamo machine of, comparatively speaking, small power. He should, therefore, for his own part, be exceedingly sorry to have to work the light in his own office direct from a dynamo such as he had seen used there. By means of the storage, however, they could light not merely the sixty lamps he had spoken of, but the 280 at one time, and so perfectly that they could not see a vibration or flicker of any kind. The difference, too, in the atmosphere as between lighting their offices by gas or electricity was so wonderful that if he had not experienced it himself he should not have credited it, the difference in point of comfort and salubrity being so marked.

The CHAIRMAN invited further discussion, but no gentleman rising to address the meeting he put the motion and declared it carried unanimously. He then moved the re-election of the retiring directors—Messrs. W. M. Bullivant, W. Ladd, and J. S. Sellon.

Mr. ROUPEL (shareholder) seconded the motion, and it was carried unanimously.

A discussion followed respecting the auditing of the accounts, and

Mr. TRENCH moved, and Mr. SCHIFF seconded, the election of Messrs. Deloitte, Dever, and Co., to act in conjunction with Mr. Alfred E. Jarvis.

Mr. NETTLEFOLD raised certain objections to the manner in which the profit and loss account had been drawn out on the present occasion. He objected most of all, he said, to the question of sales of patents being brought into profit and loss, as they really, he contended, belonged to capital. Their patents were their assets, and if they diminished their assets surely a decrease in their assets could in no sense be called profit. He thought, too, that the actual amount of cash received for patents should have been stated apart from the shares which had been received. No cash value could be put against the shares.

The CHAIRMAN thanked Mr. Nettlefold for his suggestion, but he had himself endeavoured to disabuse their minds of any idea that the shares represented so much. Whatever was distributed from the sale of patents would go towards reducing the capital of the Company. The Courts, in fact, would not allow them, even if they wished it, to divide as dividend money obtained from the sale of patents. He concluded by putting the resolution, and it was carried unanimously.

Two resolutions were afterwards passed, the first for making certain alterations in Articles 16, 54, 84, and 89, the proposed alteration of Article 44 being withdrawn. The certain resolution was as follows:—"That the contracts dated the 13th day of February, 1883, and made between La Force et La Lumiere and another, and the Electrical Power Storage Company (Limited); and the 16th day of February, 1883, made between the Electrical Power Storage Company (Limited) and the French Electrical Power Storage Company (Limited) be, and they are hereby approved and confirmed, and the directors are hereby authorised and instructed, notwithstanding anything contained in the Articles of Association, to accept surrenders of all, or any part, of the 36,000 fully paid shares of £2 each in this Company, mentioned in the said agreement of the 16th day of February, 1883. Provided always that nothing herein contained shall authorise the directors to accept any surrender of shares other than the surrenders hereby authorised."

A cordial vote of thanks to the chairman and directors terminated the proceedings.

THE GERMAN UNION TELEGRAPH AND TRUST COMPANY (LIMITED).

The twelfth ordinary general meeting of this Company was held on Wednesday, the 21st inst., at the offices, 66, Old Broad-street, E.C., Sir James Anderson in the chair.

Mr. WM. PAYTON (the secretary) read the notice convening the meeting, and the report of the directors was taken as read

The CHAIRMAN said: Gentlemen, before moving the adoption of the report, I will make a few remarks, especially as this is Easter time, and there is not a very large number of shareholders here, and the report will go to them of anything that may be said. Last year the new cable from Valentia to Greitseil was only four days laid at the time of our meeting; therefore, we had nothing to say but to express a hope that it would be remunerative. I am very glad to say that after twelve months experience I think it even exceeds the expectations that any of us had at that time. Notwithstanding the fact that we had our main cable broken between Emden and Lowestoft for three months, we still have managed to pay within one per cent. of our last year's dividend, and also to pay the five per cent. upon the new capital for the line from Valentia to Greitseil. Really I hardly expected such a fortunate state of affairs, seeing the length of time that that cable remained broken. Fortunately, however, we were in the hands of the Telegraph Construction and Maintenance Company, who manufactured the cable for us of a length of about thirty-five or, perhaps, forty miles. About twenty-five miles of the cable were not required; but whatever the length was they have not charged us with it, but have taken it off our hands with the chance of selling it as time goes on, so that we only had to pay for the cable used. The repairs cost altogether £7,000, and, putting by the usual 10 per cent. of reserve for renewal fund, and an additional 5 per cent. which was sanctioned by the shareholders until such time as the £7,000 is made up, or put back again to the renewal fund, we are still in a position to pay £5 5s. odd per cent., and the reserve stands now, I am happy to say, at something like £29,000. In fact, it is a very good reserve, but not too much considering that our cable is a very long one, from Valentia to Greitseil, crosses a good many other cables, and may cost something for repair as time goes on; but I do not think we can very well complain. Although the tariff has been raised since last year from 1s. a word to 2s., we have the anomalous experience that we have actually made an increase of traffic—an increase of the number of messages, as well as an increase in revenue, with a higher tariff. I think that is the first experience of the kind we have ever had, and it can only be accounted for by the fact of our having supplied the want of Germany for more direct communication with America, and possibly by the increase of commercial intercourse. It is a very curious experience altogether, the effect of tariff, and in the Anglo-American and Atlantic Cable Companies, as you are aware, the tariff has been raised from one shilling to two shillings within this time we are speaking of, and the experience there has been that the revenue has increased 70 per cent., and the number of words has only decreased 17 per cent., showing, I think, that the code messages have been so scientifically arranged that merchants cannot now reduce the number of words in any of their messages any further, and that a cheap tariff does not induce them to send any more words, because they have arrived at such perfection in the coding of telegrams that they can express all their wants in a few words. I think we are getting at the bottom of the difficulty or the obstacle with the merchants' code telegrams against the revenue of the telegraph companies. The companies never have stood in the way, but were the first to inaugurate the use of code words for expressing commercial matters, and we are at the point I hope where we may reap our reward by seeing a gradual increase, as the merchants have learned to express their wants with the minimum of words. Now, gentlemen, I think that is pretty much all that remains that the report calls upon me to move. I have nothing to report of a serious character, excepting, perhaps, the fact that our cable house, as we call it, at Lowestoft, has been washed away by the storms and high tides, but that is not a very expensive matter at the worst, and steps, of course, are being taken to put it right again. We are not losing any traffic in consequence of the washing away of the house. I have now, therefore, to move the adoption of the report:—"That the report and accounts of the directors for the year ending 31st December, 1832, submitted to this meeting, be, and they are hereby received and adopted, and that a dividend of 4s. 10d. per share, free of income-tax, making, with the previous distribution of 5s. 9d. per share, a total dividend for the year of 10s. 7d., or at the rate of £5 5s. 10d. per cent. per annum be now declared, to be payable on and after this date."

Mr. HERMANN GUSTAV ERICHSEN: I beg to second it.

The motion was put and carried unanimously, and without discussion.

Sir JAMES ANDERSON, the director who retired by rotation, having been re-elected,

Mr. FULLER said he had to bring to the notice of the shareholders a resolution which he felt sure they would cordially adopt when they were aware of its nature. The sound condition which this Company had attained was due entirely to the management and foresight shown by the directors in the arrangements they had made, more especially with regard to those cables which were laid during the past year. He could speak from personal knowledge of the value of the cable by which they connected their own cables with the Atlantic system, and he had much pleasure, therefore, in bringing to their notice the following resolution:—"That the remuneration of the directors for the year ending December 31, 1882, and in future, be at the rate of £400 per annum."

A SHAREHOLDER seconded the motion, which was carried unanimously.

On the motion of Mr. HENDERSON, Mr. Henry Dever was re-appointed auditor; after which a vote of thanks to the chairman and directors terminated the proceedings.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).

Report of the directors for the half year ended 31st December, 1882, to be presented at the general meeting of shareholders, to be held on Saturday, 31st March, 1883:—The annexed accounts for the half year ended 31st December, 1882, show a balance to the credit of profit and loss of £7,056 17s. 9d. The receipts, although somewhat inferior to those of the last half year, are in excess of those for the corresponding period of 1881. In the early part of December a fault of insulation occurred in the shore-end of the Bilbao cable near the Lizard, but it did not interfere with the communication; it was successfully extracted in January. The Barcelona cable was broken down from the 8th to the 31st December. It was satisfactorily and economically repaired, and has since been in excellent working order. The cost of these repairs, £751 9s. 5d., was paid out of the revenue of the half year. The directors informed the shareholders, by a circular dated 30th November last, that they had concluded an arrangement with the Eastern Telegraph Company to work the direct traffic between England and Spain on the joint-purse system. This arrangement came into force on the 1st December, and has proved satisfactory, securing to this Company a revenue during the interruption of the Bilbao cable. After paying the dividend on the Preference shares, amounting to £2,921 10s., and appropriating £200 to the reduction of the preliminary expenses account, there remains a balance of £3,935 17s. 9d. The directors deeply regret that they cannot recommend the payment of a dividend on the Ordinary shares, feeling the necessity of carrying the whole of this balance to the reserve fund, owing to the unfortunate interruptions of the Bilbao cable since the 1st January last, the repairs of which have to be provided for. The dividend warrants on the Preference shares will be payable on the 2nd April. Mr. Ettinger and Mr. Scott are the directors who retire by rotation, and, being eligible, offer themselves for re-election. Mr. Herbert R. Duke is eligible as auditor for the present year.

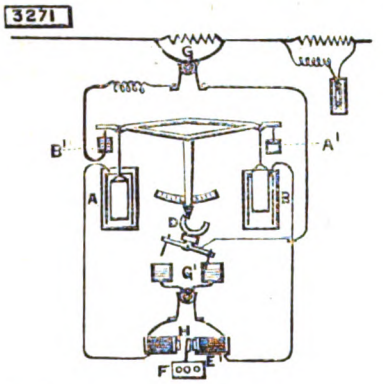
RECENT INVENTIONS.

ABSTRACT OF SPECIFICATIONS.

3271. Electrical Meters, *T. J. Handford, Southampton-buildings.*—*10th July*, 1882.—(*A communication from T. A. Edison, Menlo Park, New Jersey, U.S.*). 6*d*.

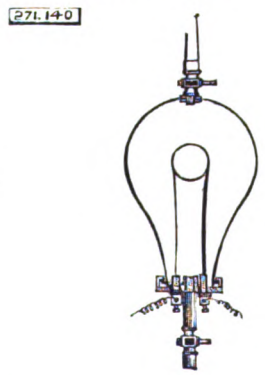
The object of this invention is the automatic registering of the electrical energy consumed in a circuit. This is accomplished, as shown in the illustration, by two plates of two cells, one from each, being suspended to a beam oscillating upon its centre. The cells are arranged in a shunt circuit around resistance placed in the line of one of the main conductors of a house circuit, and have connected with them a circuit-making-and-breaking device operated by the beam, by which the current of the shunt always passes through the



cell, having its electrodes elevated or depressed according to whether the meter is acting, by depositing upon or stripping from the suspended electrodes. At the end of each month the direction of the current through the cells and the connections of the circuit controller are reversed, and the suspended electrodes become the anodes of the cells if they have been acting as the cathodes during the previous month, or *vice versâ*. Referring to the illustration, A and B are the cells, A^1 and B^1 a dashpot and mercury cup respectively; D is a circuit controller, with arms provided with points dipping into mercury cups; E E^1 are electro-magnets acting upon armature lever H, the movement of which works F, the register; G G^1 are hand-operated current reversers.

271,140. Combined Electric Light and Gas Burner, *William A. Shaw, Brooklyn, N.Y.*—*Filed May 3rd*, 1882.

Claim.—The combination substantially as hereinbefore set forth of the gas conduit or chamber,



the incandescent electric conductor enclosed within said conduit, and the illuminating gas burner attached to the said conduit.

3244. Incandescing Electric Lamps, *T. J. Handford, Southampton-buildings, 8th July*, 1882.—(*A communication from C. A. Van Cleve, Metuchen, Middlesex County, New Jersey, U.S.*)—(*Void.*) 2*d*.

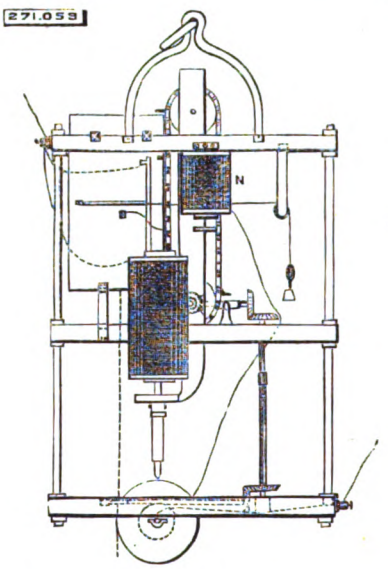
To remove the aqueous vapour remaining in the globes of incandescing lamps after being exhausted of air by the mercury pump, the inventor introduces and seals in the globe phosphorus anhydride or some such compounds.

3232. Electric Clocks, *J. P. A. Schlaefli, Soleure, Switzerland.*—*7th July*, 1882. 6*d*.

This relates to an improved secondary electric clock to be actuated by a weight raised periodically by a current sent at frequent intervals from a central station.

271,059. Magazine Electric Lamp, *Alenza T. Gifford, Providence, R.I.*—*Filed January 12th*, 1882.

Claim.—(1) In an electric arc lamp, the combination with the magazine provided with devices for discharging single pencils successively therefrom, of the endless chain provided with projections for striking the pencils discharged and forcing them toward the opposite electrode, and suitable devices for operating said chain automatically as the result of increased resistance in the lamp circuit, substantially as described. (2) The combination with the magazine provided with the automatically closing doors and automatic means for discharging the pencils through the doorway of the endless chain provided with means for opening said doors and driving the discharged pencils forward longitudinally, substantially as described. (3) The magazine provided with the automatically closing doors, means for automatically discharging the pencils, and a guide for a single pencil outside of said doors, substantially as described. (4) The combination with the maga-



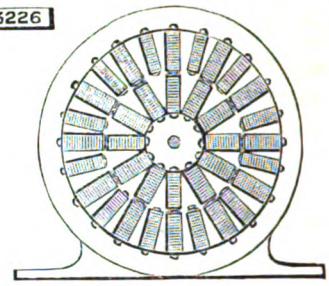
zine provided with a guide for single pencils, and with automatically closing doors, of the travelling chain provided with means for driving the pencils longitudinally, and automatic devices for opening the doors to permit a fresh pencil to pass, substantially as described. (5) In an electric arc lamp, the combination, with the electro-magnets for lifting a carbon pencil from an opposite electrode to establish the arc, of an electro-magnet of higher resistance in a derived circuit around such magnets, a feed operating magnet in a shunt circuit, and shunting devices operated by said magnet of higher resistance for shunting the main current through said feed operating magnet, substantially as described. (6) The combination with the electro-magnets N^1, arranged in a shunt circuit for operating the pencil feed and the electro-magnet N of higher resistance, arranged in a derived circuit of the levers M and M^1 carrying armatures for such magnets respectively, a circuit breaking or shunting device operated by the first-named lever to direct the main current over the coil of magnet N^1, and means for restoring said shunting device to its normal condition by the action of the lever M^1, substantially as described.

3172. Voltaic Batteries, *J. Imray, Chancery-lane.*—*5th July*, 1882.—(*A communication from P. Jablochkoff, Paris.*) 6*d*.

This consists in the employment of sodium or potassium as the negative element in a battery, the voltaic action being by this means produced by air alone, in place of the acid usually employed. The other element is either carbon, or spongy platinum, or metal gauze, the porosity of which is necessary to admit air to act on the oxidisable metal, a porous material, such as thin paper, being interposed between the two elements.

3226. An Improved Electro-magnetic Motor *E. Toynbee, Willesden.*—*7th July*, 1882. 6*d*.

This motor consists of a series of concentric, parallel, revolving, and stationary electro-magnets, so arranged that the whole shall form one or more continuous rings of magnetic poles, enclosing the whole, or nearly so, of the magnetic lines



of force. The whole of the revolving or stationary magnets are commutated at each segment of the circle, thus producing a maximum and uniformly continuous rotary motion. Great velocity can be obtained, the inventor states, with no heating, and without much wear and tear. The apparatus is shown in end view in the accompanying illustration.

3171. Apparatus for Governing Marine Engines by Electricity, *W. W. Girdwoods, Poplar.*—*5th July*, 1882. 6*d*.

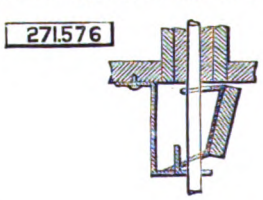
This relates to a combination of a float placed in a tube close to the propeller of a steamship and connected by chains with a wheel placed in close proximity to an electro-magnet, the armature of which is connected with the throttle valve of the engine to be controlled. The action of the wheel causes the circuit of the electro-magnet to be broken or closed, and the armature attracted or not, according to whether the float descends or ascends, owing to the motion of the sea. When the float descends it closes the circuit, and by means of the electro-magnet, armature, and gearing, the throttle valve, but when it ascends the circuit is broken and the valve opened.

3255. Incandescent Electric Lamps, *J. H. Gardiner, Camberwell.*—*8th July*, 1882. 6*d*.

This relates to a blow lamp for constructing the glass globes of incandescent lamps, by means of which either a large flame, covering a wide area, or a pointed flame, to strike one spot only, can be obtained at will, thus obviating the use of two such lamps; also to a new pump for exhausting the globes of air, which operates by the continual reproduction of the Toricellian vacuum; and lastly, to a new method of mounting the lamps in sockets for use.

271,576. Electric Arc Lamp. *Joseph R. Finney, Pittsburg, Pa.*—*Filed November 8th*, 1882.

Claim.—(1) The combination in an electric arc lamp, of a hollow electro-magnet, through which the feed rod passes, a pivotted armature arranged at the side of the feed rod, and a perforated plate or ring attached diagonally to the armature and encircling the feed rod, substantially as and for the purposes described. (2) The combination in an electric arc lamp, of an electro-magnet, a feed rod, a pivotted armature arranged at the side of the feed rod and beyond the vertical plane of the core of the magnet, and a perforated plate or ring



attached diagonally to the armature and encircling the feed rod, substantially as and for the purposes described. (3) The combination in an electric arc lamp of an electro-magnet, an armature capable of an axial movement, and having a slotted projection to encircle the feed rod to keep it from falling, and a circular clamp to grasp the feed rod, and a stirrup or support to sustain the armature, substantially as and for the purposes described. (4) The combination in an electric arc lamp of an electro-magnet, an armature capable of a radial and an axial movement, and a stirrup or support for the armature, having a guide pin to guide the armature in its movements, substantially as and for the purposes described.

Digitized by Google

SLIP

THE MAXIM-WESTON ELECTRIC COMPANY.—Mr. T. R. Comyn has been appointed secretary of this company in place of Mr. F. H. Landon, resigned.

BRUSH MIDLAND ELECTRIC LIGHT AND POWER COMPANY.—The offices of this company have been removed from 31, Lombard-street, to 4, Great Winchester-street-buildings, E.C.

ELECTRIC LIGHTING IN NEW ZEALAND.—The New Zealand Electric Light Company are to light Lyttelton with sixteen Brush lights, equal to 3,200 candles, says the *Colonies and India*.

TRINIDAD.—The latest news from Trinidad states that the telegraph steamers the "Duchess of Marlborough" and "Grappler" had been engaged in repairing the cables between Trinidad and Grenada, and Grenada and St. Vincent.

TENDERS WANTED FOR ELECTRIC LIGHTING.—The Committee of the Huddersfield Fine Art and Industrial Exhibition are inviting tenders for lighting portions of the exhibition building by electric light. Plans and particulars can be had of Mr. A. Keen, the secretary.

THE RATING OF WIRES.—The Postmaster-General was summoned at the Willenhall (Staffs.) Police Court a few days since for non-payment of poor rates, the unpaid rate being in respect of telegraph poles and wires within the township. The usual order for payment was made.

MR. LEVER'S PREMIUM FOR A MINERS' LAMP.—The Council of the Society of Arts having been requested by Mr. Ellis Lever to appoint one of the judges to award the prize of £500, which he has offered for a miners' safety lamp, have complied by appointing Professor F. A. Abel, C.B., F.R.S.

TELEGRAPH WIRE, &c., WANTED.—The Lancashire and Yorkshire Railway Company are inviting tenders for the supply of telegraph fittings, wire, tin, zinc, &c., for the next half year. Further particulars and forms of tender can be had at the Stores Department, Miles Platting, near Manchester. Tenders must be lodged with the secretary, Hunt's Bank, Manchester, by 10 a.m. on April 9.

THE ELECTRIC LIGHTING ACT.—Major R. Y. Armstrong, of the Royal Engineers, at present stationed at Chatham, has been appointed by the Board of Trade to superintend the carrying out the provisions of the Electric Lighting Act of last session. Captain P. Cardew, R.E., has been appointed instructor in telegraphy at the School of Military Engineering, Chatham, in the place of Major Armstrong.

ELECTRIC LIGHTING IN SEWERS.—Six Brush lamps were used to light a portion of the sewer which distributes its contents over the market gardens of Gennevilliers, Paris, up to a recent date, when, however, the floods put a stop to this mode of lighting. Our contemporary, *L'Electricité*, gives an illustration of the huge sewer, as lighted by the above lamps, and expresses the hope that the Municipal Council of Paris will continue this means of illumination.

ELECTRIC LIGHTING IN DUNDEE.—A correspondent writes to say that the paragraph in our last issue referring to the adoption of the Brush light in Dundee is incorrect in some particulars. According to him the arrangement completed between the Corporation and the Brush Company of Scotland is that they have withdrawn their application for a provisional order and allowed the company to proceed unopposed. The name of the superintending electrician also should be Martin, not Morton.

CITY AND GUILDS OF LONDON INSTITUTE.—We notice that the summer term of the day school of this institute commences for new students on the 12th April. Particulars as to the fees, &c., can be had at the Technical College, Tabernacle-row, E.C. The 1883 Technological Examinations will take place on the evening of the 30th May, at 7. A programme, with a syllabus of each subject and last year's papers, can be had of Mr. P. Magnus, at the central office of the Institute, Gresham College, E.C.

THE POSTMASTER-GENERAL AND THE TELEGRAPHISTS.—Mr. Fawcett has issued the following special notice to the telegraphists: — "The Postmaster-General observes that attempts are being made to press him to re-open and revise the question of the re-organisation of the telegraph service, which, after the most attentive consideration, and at great cost to the taxpayer, he settled in 1881. He thinks it right to inform the staff that he has no intention of re-opening the question involved in that settlement."

AN ARSENAL STRUCK BY LIGHTNING.—A telegram from Vienna, dated March 23, says that "on the 10th inst. the arsenal of Cettinje was struck by lightning. The building is of very primitive construction, and contained considerable stores of gunpowder and ammunition. The central portion was blown up. Some brave men, however, at the risk of instantaneous destruction, threw out the chests of powder and ammunition into the snow, whence the men and women who had collected carried them to a safe distance."

A WEST END LIGHTING STATION.—We are enabled to state that the Swan United Electric Light Company are sufficiently confident of obtaining their provisional order for lighting a large district in the west of London, of which the Victoria Railway Station may roughly be taken as the centre, that they have commenced to erect the necessary buildings. These are so far forward that they have reached the first floor level. Engines and boilers for the supply of 1,000 horse-power have been ordered for this station, and are now approaching completion.

ELECTRIC LIGHTING IN THE CITY.—A report on the works carried out by the Commissioners of Sewers during last year has just been issued by their engineer, Colonel Haywood, who is its compiler, and includes, amongst other matters, electric lighting. It gives a history of electric lighting in the City during 1881 and last year. As the substance of it has already appeared in these columns at different dates, and as our space is already far too small for the matter awaiting insertion, we shall content ourselves with notifying its publication to our readers.

ELECTRIC LIGHTING FOR VIENNA.—A telegram to the *Standard*, dated Vienna, Wednesday night, says:—"The Vienna Town Council, at its sitting to-day, considered the proposal of the Anglo-Austrian Brush Company to supply Vienna with arc (Brush system), and incandescent lights on the Lane-Fox system, and with electric motive power by laying down cables throughout the entire city. In return for this the company demands the exclusive right to supply the city with electric lighting for a period of fifty years. To this long term there is a strong opposition. The council has not yet come to a decision, but I believe that the monopoly desired by the company will not be granted."

IRIDIUM PLATING.—Mr. W. L. Dudley has announced before the Ohio Mechanics' Institute that the problem of electro-plating with iridium has been solved by employing a

Digitized by Google

suitable solution of the metal and properly regulating the electric current. The solution (says the *Engineering and Mining Journal* of New York) is kept at uniform strength by using a plate of iridium as the anode. The metal is deposited in the reguline state, and takes a good polish. A buffing-wheel that will grind off nickel plating in a few moments only serves to polish the iridium. Thin platinum foil, coated with iridium, retains its flexibility; and if the coating is not too thick, it will not readily scale off.

Electric Lighting at the Mansion House.—Some changes have been made in the arrangement of the engines and machines connected with this installation. The whole was removed a few days since from the basement, where it was set up at first, to one of the lower passages beneath. This work necessitated no small amount of care and skill, but was successfully carried out in a very short time by the contractors, Messrs. R. E. Crompton and Co. Advantage has been taken of the removal to erect two Otto gas engines in place of the one hitherto in use, so that all chance of a total breakdown might be removed. The engines are so arranged that if one stopped the other could be set going with scarcely any delay.

The Law Courts.—The lighting of the Law Courts is now complete throughout, with the exception of a few trifling fittings. Twenty-two courts, the whole of the bar corridors, and staircases, approaches, robing and refreshment rooms are lighted by means of Swan lamps. The central hall has six Crompton arc lamps of the latest pattern, but at present it is not found necessary to use these on account of the light afternoons and evenings. Some of the courts, however, are so dark on a cloudy afternoon that steam is always kept up and light supplied whenever required. As our readers are well aware, the whole of this work has been carried out by Messrs. R. E. Crompton and Co., engineers to the Swan United Electric Light Company.

The Telephone in London.—In an annual article (vide *The Electrician* for January 13, p. 205) we gave some statistics showing the progress made by the United Telephone Company during last year. At the time we wrote the total number of subscribers to the company's exchange was 2,247. On the 27th of January it had risen to 2,442, on the 28th of February to 2,541, and on the 28th of March, that is Wednesday last, the total number was 2,606. The number of calls per day in July last averaged 14,000. If this figure be compared with the following it will be seen that considerable progress has been made. Thus, on the 14th of March this year the number of calls was 18,879; on the 15th, 18,910; on the 16th, 19,948; (the 17th, being a Saturday, cannot be compared with ordinary days); on the 19th, 19,654; on the 20th, 19,958; on the 21st, 19,948; and on the 22nd, 20,715. For these figures we are indebted to the courtesy of the company.

Electric Lighting at Oxford.—An installation of six Pilsen arc lamps and 100 incandescent lamps has just been completed on the premises of the Union Society, Oxford. The Pilsen lamps are used for lighting the debating hall, the library, the smoking room, and outside, while the incandescent are placed in the library, entrance hall, telegraphic room, smoking room, and general offices. The power is derived from an Otto gas engine, provided with silencing chamber. The dynamo machines are placed in a house specially constructed in the grounds of the Union Society, and are fitted with the usual electrical apparatus. The work has been carried out by the Pilsen, Joel, and General Electric Light Company, of London. The fittings are plain and substantial, and afford every facility for regulating the lamps. No doubt the members will appreciate the advantage of the pure atmosphere afforded by the electric light as compared with gas.

Our Parisian Confreres.—*L'Electricité* informs us that the first of a series of monthly dinners, to which all interested in electricity were invited, took place on the 21st March, under the presidency of M. Cochery, Minister of Posts and Telegraphs, at the Café Durand, Place de la Madeleine, Paris. The initiative in this case is, we are told, due to M. le Comte Hallez d'Arros, the editor of *L'Electricité*. The interior of the café was lighted by means of 82 Swan lamps, the current being supplied by accumulators furnished by the French Electrical Power Storage Co. These accumulators also fed two arc lamps placed in the street outside the café. The total number of guests was sixty, many of whose names are almost as familiar here as they are in Paris. Speeches were made after the dinner by M. Cochery, M. Berger, M. le Comte d'Arros, and others. It was announced that in future a similar *réunion* of electricians would take place on the 21st of each month.

Electric Light in Lahore, India.—The installation at the Scinde, Punjaub, and Delhi Railway Station consists of:—Two platforms, four lights each, = eight; one outside platform, two lights, = two; goods yard, three lights, = three; two booking offices, one light each, = two; and front entrance to street, one; or a total of sixteen lights. The circuit is nearly two miles long. The power is supplied by an old locomotive engine, which is also used for driving the machinery of the company's printing presses. Coal being very expensive in the Punjaub wood only is used as fuel. The Scinde, Punjaub, and Delhi Railway have purchased the plant, owing to the success of the first trial, and are about to purchase more. Mr. E. W. Lancaster carried out the work for the Eastern Electric Light and Power Company of Bombay. It is expected that the well-known Golden Temple of Umritsar, India, will soon be lighted by the same system. A subscription is being got up by various native princes and others for the purchase of a plant. This will be the first temple or native place of worship lighted by electricity, or by Christians. All leather, grease, and other ingredients, &c., will be avoided so as not to violate native caste.

Long Distance Telephony.—A telegram from the *Standard's* New York correspondent appeared in a recent issue of that paper, giving an account of a telephone trial which took place between New York and Chicago on the 25th inst., over a distance of 1,000 miles. The telegram went on to say: "Previously the longest distance over which a message had been sent was 700 miles, between New York and Cleveland. The present result is not due solely to the telephone, although that possesses some novelty, but is mainly due to a novelty in the conductor; this consisted of a steel wire core copper plated, the electrical resistance of which to Chicago was only 1,522 ohms against upwards of 15,000 ohms, the average resistance of ordinary iron telephone wire." All this may or may not be true. Time will show. In the meantime, and until further details have come to hand, we advise our readers not to swallow too much of the information given above. As far as telephoning over 1,000 miles of wire goes, the Americans have been beaten by Australia. We have it on the best authority that 1,500 miles and more have been telephoned over in that country, and speech distinctly heard. Whether the success of the trial in America really did lay with the wire used time alone can show.

Electric Lighting and the Board of Trade.—The

Digitized by Google

Chelsea Vestry have addressed a letter to the Board of Trade, which contains the following:—"As regards the main features of the Chelsea Electric Lighting order, the vestry beg to submit that, in accordance with your suggestion, they have discussed the same with Mr. Moulton, and have practically agreed on the proposed area of supply. As to any further points upon which the promoters and the vestry may differ, it may be convenient to reduce them to writing and submit them to the Board of Trade for final decision. In the vestry's letter to the Board of Trade on their objections to the Metropolitan Brush Provisional Order (clause 3, part B), it was suggested 'that, whenever practicable, a distributing main should be laid under the footway on each side of the street, so as to avoid the interruption of traffic and breaking up of streets which would be occasioned if the lines were laid under the roadway.' This point, the vestry have reason to believe, is also practically agreed on. The vestry suggest that the Board of Trade should add a model clause to this effect, so that, wherever practicable, other districts may secure the benefit of its adoption, whereby uniformity will be obtained." The Board, we believe, have agreed to modify some clauses so as to meet the views of the Chelsea Vestry and other critics; and it is stated that the amended clauses will be ready for the public on Monday next.

The Crystal Palace Exhibition.—This exhibition is still being added to by fresh exhibitors. Amongst the latest to appear are Messrs. Crossley Brothers, who are to light up the Italian courts with Swan lamps. Bürgin machines, supplied by Messrs. Crompton, will be used. These machines are fitted with steel fly-wheels keyed on to the dynamo spindle close to the pulley. The surface speed of these fly-wheels when the machine is running at 1,600 revolutions is nearly two miles per minute. They are said to entirely prevent the oscillation of the light, which is usually considered inseparable from the use of gas engines as motors. The Gülcher Electric Light Company, in combination with Messrs. Defries, art metal workers, have also completed their exhibit now. This company lights the mediæval courts by means of Crookes's incandescent lamps and Gülcher arc lights. The incandescent lamps are fitted into some most elegant and elaborate pendants, brackets, &c., exhibited by Messrs. Defries, the effect of which is extremely pretty, and calculated to show off incandescent lamps to the best possible advantage. The Gülcher exhibit is interesting from the fact that both arc and incandescent lamps are run off the same machine. We shall have more to say concerning this combined exhibit in a future number. Another exhibitor is Mr. Trotter, who shows his system of distributing light by means of glass globes or lanterns, the sides of which have grooves cut at particular angles so as to distribute as much light as possible. Mr. Trotter has, we hear, engaged a well known electrician, to report on his system. In the meantime, however, a very good idea of its merits can be obtained at the palace. Of miscellaneous exhibits Mr. J. Sax has undoubtedly the best collection. We shall refer to these and other apparatus as our space permits.

The Chemistry of Storage Batteries.—A paper on this subject was recently read before the Physical Society by Dr. E. Frankland. The first part dealt with the chemical changes occurring in the charging and discharging of storage batteries. Proof was given that occluded gases play, practically, no part in the phenomena of the storage cell. It was shown that the active material on the plates is lead sulphate, and that the initial action in charging is the electrolysis of sulphuric acid into hydrogen, sulphuric anhydride, and oxygen. The hydrogen decomposes the lead sulphate on the negative plate into spongy lead and sulphuric acid, whilst the oxygen decomposes the lead sulphate on the positive plate into lead peroxide and sulphuric anhydride. All sulphuric anhydride is at once converted into sulphuric acid. In discharging the initial action is again the electrolysis of sulphuric acid, which restores the coating of the two plates to its original condition of lead sulphate. The second part of the paper treated of the chemical estimation of the charge in a storage cell. This is founded upon the reactions described in the first part. As the charging of a cell is attended with the liberation of sulphuric acid, and its discharge with the abstraction of this acid from the liquid contents of the cell, it is only necessary to ascertain the specific gravity and consequent strength of the acid to determine the amount of charge in a cell at any given moment—provided, of course, that the specific gravity of the acid in the charged and uncharged condition of the cell be previously known. A suitable space for a small hydrometer in a storage cell could easily be contrived, and, if the graduated stem were made to rise above the cover, the amount of stored energy could be seen at a glance. The author stated that in the case of the cell with which he had experimented, each increase of ·005 in the specific gravity of the dilute acid meant a storage of available energy equal to twenty amperes of current for one hour.

Electric Lighting in Theatres.—"People in Paris do not seem to trouble themselves much concerning the propriety of lighting their theatres by means of electricity," says the *Révue Industrielle*. "Some months ago this question was to the fore, and the experiments carried out at the Théatre des Varietés gave rise to an enthusiasm which has now cooled down. It is suggested that incandescent gas lamps should be introduced at the opera, but the matter is of sufficient importance to think twice about it; and, again, its consideration has been entrusted to an official committee, which does not promise us a quick solution. So it happens that we must go abroad for our facts. In London, the Savoy Theatre, in Brünn, the Municipal Theatre, are both lighted by electricity, which has also just been adopted at the Parc Theatre in Brussels. Here the Edison system is in use, and the Brussels press is pleased to notice that the light is soft, regular, adaptable to any circumstances, and does not overheat the air or pollute it. The installation comprises 250 to 300 lamps, to judge from the fact that the dynamo requires 35 h.-p. Under these conditions competition with gas is possible, although the net cost of one centime per hour per lamp seems to us a little too low, depreciation and interest put aside. As a rule we must reckon that electric lighting on the incandescent system will cost, everything included, for an installation of 4 to 500 lamps of 2 carcels from 80 to 100 francs per lamp, and that the total net cost for an average of 500 hours per year will not be much lower than 4 centimes per lamp per hour, or 2 centimes per carcel per hour (a carcel = 9·6 English candles). Admitting that 105 litres of gas correspond to a carcel per hour (a litre = 61·0254 cubic inches), and this consumption is exceeded in practice, it would be advantageous to employ electricity so long as gas cost more than 16 centimes per cubic metre. Theatres, shops, and workshops are the only places that can hope to realise this economy, whether it be on account of the large number of burners they need, or the facilities for erecting the lamps and machines when the motive power is already at hand. The introduction of incandescent lamps into ordinary houses seems to us to be dependent upon the progress made in the construction of accumulators and primary batteries. The gas companies need not, therefore, disquiet themselves." When, however, two or three more stations like

Digitized by Google

Edison's, in New York, have got to work, it is possible that our excellent contemporary may change its mind. We certainly do not think that any progress that may be made in the construction of primary batteries is likely to have much effect upon the question of the introduction of the incandescent light into private houses.

Remarkable Electrical Discovery.—Under this head the following paragraph appeared in *The Times* of the 24th inst., and has since gone the round of most English journals: "Applications of electricity are not only making rapid progress in every part of Europe, but also in the southern hemisphere. There come, indeed, from Otago, New Zealand, details of an invention as marvellous as any yet recorded in the annals of electrical science. The Rev. Mr. Gilbert, of Christ Church, in a recent address, told his audience that it was now proved to be possible to convey, by means of electricity, vibrations of light—not only to speak with your distant friend, but actually to see him. The electroscope—the name of the instrument which enabled to do this—was the very latest scientific discovery, and to Dr. Guidrah, of Victoria, belonged the proud distinction of being its inventor and perfecter. Mr. Gilbert stated that a trial of this wonderful instrument had taken place at Melbourne, in the presence of some forty scientific and public men, and that it had been a great success. Sitting in a dark room, they saw projected on a large disc of white burnished metal the race course at Flemington, with its myriad of active beings. Minute details stood out with perfect fidelity to the original, and as they looked at the wonderful picture through binocular glasses, it was difficult to imagine that they were not actually on the course itself, and moving among those whose actions they could so completely scan." In *The Electrician* for the 5th of February, 1881 (Vol. VI., p. 141), under the title of "The Telectroscope," we gave an account of an invention of M. Senlecq, of Ardres, in France, to which he had given that name. It may not be out of place to quote here the first few lines of that article. They are as follow:—"This apparatus, which is intended to transmit to a distance through a telegraphic wire pictures taken on the plate of a camera, was invented in the early part of 1877 by M. Senlecq, of Ardres. A description of the first specification submitted by M. Senlecq to M. du Moncel, member of the Paris Academy of Sciences, appeared in all the continental and American scientific journals. Since then the apparatus has everywhere occupied the attention of prominent electricians, who have striven to improve on it. Amongst these we may mention MM. Ayrton and Perry, Sawyer (of New York), Sargent (of Philadelphia), Brown (of London), Carey (of Boston), Tighe (of Pittsburgh), and Graham Bell himself." In March, 1881, Professor Perry described his own and Professor Ayrton's methods of carrying this invention out, in the Cantor Lectures which he was then delivering at the Society of Arts. These lectures will also be found in Vol. VI. of *The Electrician*. Perhaps the Rev. Mr. Gilbert, of Christ Church, New Zealand, would change his mind about "the very latest scientific discovery," of which, according to him, Dr. Guidrah is the "inventor and perfecter," were he to read the articles mentioned above, for we must, perforce, conclude that he is unaware of their existence.

Electrical Transmission of Power.—Last week a paper on the above subject was read by Mr. W. M'Whirter, A.S.T.E., at Barrow-in-Furness, under the auspices of a local debating society. In the course of his paper Mr. M'Whirter gave some calculations as to the power available at the present time within a short distance of Barrow. He said:—"Through the kindness of Mr. W. B. Kendal, I am able to lay some facts before you in relation to the water power running to waste within a reasonable distance of Barrow. The height of Windermere is 134ft. above the sea level, and the average discharge from the lake is about 18,000 c.f. per minute; within three-quarters of a mile of foot of lake, a head of 25ft. can easily be obtained, at this point the theoretical h.-p., would be 850 or, say, 500 effective. Before reaching the sea, however, a total working head of fully 100ft. can be obtained, and this, taking the same ratio as above for effective work, would give us over 2,000 h.-p. The distance of the Lake Foot from Barrow would not be more than 20 miles, and a copper conductor of $\frac{1}{4}$ might easily carry the current; of course a wire would be required there and back of a total length of, say 40 miles. I estimate that such a circuit could be erected on overhead poles at about £100 per mile. If it were actually necessary to put the wires underground, then the cost would be, at least, five times as much, or, say, £4,000 for open wires, and £20,000 for cables laid underground. At the above distance of the 2,000 h.-p., put into the circuit using an E.M.F. of 80,000 volts, there would be lost in transmission only 17 h.-p. Should the amount of power available at Windermere not satisfy you, then there are other rivers to fall back upon, all within reasonable distances. The Kent has the same average discharge as the Leven, and the Lune has about four times that amount. Why, however, the question may be asked, go to Windermere. Is there no place more convenient? The area of the Cavendish Dock is 6,000,000 square feet, with an average depth of about 10ft., the height of the top water being 23ft. above low water channel. Now, supposing we take the available fall as 10ft., which is certainly very low, we would, from this source alone, running out once per day, obtain a theoretical value of 1,800 horse-power, or, say, 1,200 actual; but if we could run it out twice per day, and also make the incoming current do work, then we can easily have over 4,000 horse-power available. This alone would, I believe, drive all the machinery in Barrow. But further, the width of Walney Channel, opposite Piel, is 800 yards, with a sectional area of 40,000 square feet; the average rise of the tide is 24ft., with a velocity of 400ft. per minute. I have been asked if 50,000 horse-power can be got at this place. For my own part I see no difficulty in recovering much more than that, and I, for one, am sanguine that the day is not far distant when the great natural forces, such as I have just mentioned, will all be utilised, and when that time comes I feel sure that Barrow will not be left behind in the van."

The South Eastern and Provincial Brush Companies.—A circular has been addressed to the shareholders in the above electric light companies by their manager, Mr. George Offor, from which we quote the following paragraphs. After referring to the provisional orders for which both companies have applied, and which have been recorded in *The Electrician*, Mr. Offor goes on to say:—"The Town Council of Colchester having consented to the grant of a license from the Board of Trade, arrangements have been made for supplying electricity to the residents in High-street and Head-street—which comprise two of the most important thoroughfares of the town—a lighting station has been fitted up with the necessary machinery, dynamo machines, &c., and several shops, besides the Red Lion Hotel, have already been supplied with incandescent lamps, and your directors hope before next winter to complete in this town the most important installation of electric lighting yet undertaken in this country." We may remark that this paragraph refers to the South Eastern Company only. What follows has reference,

Digitized by Google

however, to both companies, and to the patents in which they have secured an interest. Mr. Offor describes these patents as follows:—"1. A secondary battery, of a more perfect description than any hitherto introduced, and which has been worked for more than five months with complete success in the offices of this company. 2. An automatic arrangement for regulating the supply of current to the batteries, in the form of a master cell, which cuts off the current when the accumulators are fully charged, and thus prevents the injury to the plates owing to the generating of free gas, which causes their destruction under other systems. 3. A meter for registering the quantity of current used and constructed so as to enable householders to ascertain at any moment the consumption of electricity in any form of incandescent lamps employed. 4. A regulator for automatically keeping the current of electricity constant. 5. An improvement in the construction of incandescent lamps, by means of which the duration of the carbon filament is prolonged, and the light increased. 6. A lamp-holder and switch combined, and a telescopic sliding electrolier, which can be raised or lowered without extinguishing the lamps. 7. A circuit-shunter, by which if a lamp be broken, a reserve lamp can be immediately lighted in its place automatically. 8. An improvement in dynamo machines, providing for currents of different tensions to be taken off at the same time, and especially adapting the machine as a motor for tramcars, &c." Mr. Offor goes on to say that, "As the business connected with these patents developed, it was found that it could be more conveniently carried on as a separate company in which all the interests involved could be consolidated, and in consequence a company has been formed called 'The Consolidated Electric Company,' with a nominal capital of £100,000, in fully paid-up shares of £1 each, of which both companies hold 20,000 shares as representing their interest in the profits of the company. The working capital is supplied by the Provincial and the South Eastern Companies jointly, on debentures bearing 8 per cent. interest, repayable by 50 per cent. of the nett profits, as shown in the audited balance sheets. The Consolidated Electric Co. will be managed in the same offices and by the same directors and staff as the two companies above named with the addition of James Paxman, Esq. (of Davey, Paxman, and Co.), of Colchester, and J. Kincaid, Esq., C.E., of London, as additional directors. A suitable factory has been taken at 67A, Cow Cross-street, London, which is now being fitted with the necessary machinery and plant. The manufacture of the accumulators and other patented articles, besides motors, switches, cut-outs, safety fuses, ammeters, voltmeters, and all kinds of electrical apparatus, will, I hope, be in full operation during next month. The method of electrical distribution adopted will be kown as the B. T. K. system, those letters forming the initials of the three inventors, Messrs. Beeman, Taylor, and King."

Gas versus Electricity.—A paper on this subject was read a few days since by Professor Barrett before the Royal Society of Dublin. During the reading of the paper and the discussion, which occupied more than one evening, the theatre of the society was lighted by means of thirty-two Swan lamps, supplied and fitted up by Messrs. Edmundson and Co., of Dublin and London, the current being supplied by a Siemens dynamo. We make the following extracts from a report of Professor Barrett's paper:—"In order to arrive at a satisfactory conclusion he said that they must compare gas under the best known conditions of burning with the results of private experience of the electric light. Furthermore, they must take as the price of gas not that which might happen to be paid for it to private gas companies, but the price at which gas could profitably be sold when the gas works were in the hands of municipal authorities, with an able and energetic secretary managing the gas works. Under such conditions they found that, with a good burner, from four to six times as much light could be obtained per cubic foot of gas as from the common burners generally in use. Secondly, by carburetting gas with some hydrocarbon, such as naphthalene, upwards of 60 per cent. was saved in the cost of gas lighting. Thirdly, under efficient corporate management of gas, such as existed in Birmingham, Leeds, Carlisle, and other towns, gas could be sold at a profit at 2s. per 1,000 cubic feet. If all those conditions were fulfilled he affirmed that in the present stage of electric lighting gas was the cheaper illuminant, although exceptional cases existed where water power was to be had, and gas works were absent, and in which electric lighting was more economical. Such a case was that of Mr. Barton's house at Glendalough. The cost of the installation of the electric light was the main item, and that cost was only worth incurring where there was a very large amount of artificial light needed, such as in factories, &c., and then only when a large amount of night work was done. The time limit when children were employed in factories was 277 hours of darkness a year, and at that limit the electric light did not pay. When 1,000 hours were required per year then it began to be profitable; and the larger the amount of time it was needed the more favourably it compared with gas. The comparative results of electric and gas lighting as tried in Crossley's Mills, Halifax, were as follows:—For 277 hours in the year the cost of the arc electric light was 8s. 4d. per hour, while an equal amount of gaslight cost 3s. 7d. per hour when the gas was 2s. 6d. per 1,000 cubic feet; 4s. 6d. per hour when the cost of the gas was 3s. 4d. per 1,000 feet; and 5s. 5d. per hour when the cost was 4s. 2d. per 1,000 feet. When, however, 1,000 hours of artificial light were required then the cost of the electric light became 3s. 5d. per hour, while the cost of the gaslight remained the same. But the arc electric light was too dazzling for rooms, and required constant attention. With regard to the incandescent electric lamps, the filaments used in them lasted for about a thousand hours per lamp. No doubt great improvements would be effected in storage of the electricity and in the machinery requisite for electric lighting." In the course of the discussion which followed, Mr. Wigham spoke of the loss which occurred from the bad burning of gas. He pointed out that the lighthouse gas burner exhibited in the theatre by Messrs. Edmundson burned 244ft. of gas in an hour, and gave a light equivalent to 9·87 candles for each cubic foot of gas consumed. In Irish lighthouses nine of these lights were employed, and only two in English lighthouses. He was not favourable to the adoption of the arc light in lighthouses, as it had not the requisite fog-piercing power.—Mr. M. A. Fahie thought that the great stumbling block in the way of electric lighting at the present time was the enormous charge made for the necessary apparatus.—Mr. Moss mentioned the results of his experience in the employment of the electric lights in the theatre in which they were sitting. The total cost of lighting it with electric lamps was 3s. 2d. for three hours each evening, and that represented the cost of machinery, fuel, wages, &c. Coal gas, which gave considerably less light, would cost 3s. 9d. for the same time, but extra expenses for repairs, &c., connected with the electric light would probably bring the cost of the latter up to about the same. He believed that electric lamps would be particularly well adapted for a library.

ELEMENTARY ELECTRICITY.

VIII.

The action of Voss's machine for a short time after it is first started is precisely the same as that of the replenisher. In it two paper armatures with small pieces of tinfoil beneath them are attached to the back plate of the machine, and serve as inductors. The carriers consist of six circles of tinfoil attached to the revolving plate. The contacts are made upon metallic buttons attached to the carriers by little brushes of gold tinsel. Two of these brushes are attached to a cross arm, or diagonal conductor, and serve to put the opposite carriers into connection with one another. The others are connected with the paper armatures by means of a metal arm. A very small difference of potential between the paper armatures, which they generally acquire by unknown or accidental causes, is sufficient to start the action of the machine, and to charge up the armatures to a high potential.

When the armatures are strongly electrified a new action begins to take place. Not only does the electricity pass from the metallic brushes to the metal carriers, but it begins to stream from the rows of points, which are attached to the diagonal conductor on each side of the brushes, upon the glass plate, so that the portion of the plate which is opposite the negative inductor becomes positively electrified, while that which is opposite the positive inductor becomes negatively electrified. The revolving glass plate thus begins to act as a carrier itself, and presently its positively electrified surface comes in front of the negatively electrified armature. The carrier comes in contact with the brush when it is between it and the armature, and thus gives up its charge to the armature; but the glass cannot dispose of its charge in this way, but retains it until it comes opposite the points of the prime conductor, when negative electricity streams off the points upon the plate, neutralising the positive charge of the plate, and even electrifying it negatively under the inductive action of the armature. This causes the prime conductor to become positively charged. The opposite prime conductor becomes negatively charged at the same time and in the same way. The circuit of the electricity is completed in the sparks which pass between the conductors. The portions of the glass plate which we are considering having passed in front of the prime conductors now come opposite the diagonal conductor, when the same action takes place as before, unless the revolving plate has been charged by the prime conductors to the full extent which the armatures can induce, in which case the diagonal conductor becomes inoperative. If the discharging knobs of the prime conductors are placed in contact so that there is no resistance to the passage of electricity from one to the other, the prime conductors take the place of the diagonal conductor in charging the glass plate and carriers by radiation, but if the conductors are separated, and happen to be charged nearly to the same potential as the armatures, then very little discharge will take place from the points of the prime conductors, and the diagonal conductor alone will maintain the action. If the machine be worked in the dark, it will be observed that if the prime conductors are in contact, or separate but uncharged, the brushes and glows will appear on the points of the prime conductors, and not on the diagonal conductor. If the prime conductors are separated by a considerable distance, the brushes and glows on their points will diminish as they become charged, and will appear on the points of the diagonal conductor, where they will steadily increase in intensity; and if the prime conductors be separated to the full striking distance of the machine, the discharge from their points will disappear just before the spark passes, but it will reappear on the prime conductors and disappear from the diagonal conductor immediately after the spark.

It is generally found in fine weather that the potential of the air increases as we ascend from the earth's surface, the rate of increase being generally equal to the electromotive force of several Daniell cells for each foot through which we ascend. Sometimes the difference of potential per foot exceeds the electromotive force of 100 Daniell cells. The potential of the air at a given height above the earth is one of the quantities continually recorded at fixed observatories.

If the air be at a positive potential, and a conductor be surrounded by the air, but placed in connection with the earth, the conductor will be at potential zero, and will be negatively electrified. In order to bring the conductor to the potential of the air, it must be placed on an insulating support, and then deprived of its electrification.

If it were possible to remove the whole of the outer surface of the conductor, the induced electrification might be carried off with it and the conductor left unelectrified, and, therefore, at the potential of the air around it. On connecting the conductor with an electrometer the latter would not, however, attain the potential of the air unless the capacity of the conductor were very great compared with that of the electrometer.

If the conductor be insulated and connected with the electrometer, and if a very sharp point be attached to the conductor, electricity will pass off the point so long as there is any considerable charge induced upon the conductor, that is, so long as the potential of the conductor differs considerably from that of the surrounding air; but, unless it is extremely sharp, the point will become inefficient before the potential of the conductor approaches very closely to that of the air.

If a burning match or gas flame be in communication with the conductor, the flame will form a part of the conductor itself, and will be negatively electrified so long as the potential of the conductor is less than that of the air immediately surrounding the flame. But the negatively electrified flame is continually being dissipated into the air, carrying its negative electrification with it, and being replaced by another flame, as it were, which in turn becomes electrified at the expense of the conductor, and this process goes on until the conductor, and the quadrants of the electrometer connected with it, are raised to the same potential as the air which *immediately surrounds the flame*. In connection with his portable electrometer, Sir William Thomson employs a burning slow match to raise the potential of the plate of the instrument to that of the air in the neighbourhood.

Sir William Thomson's water dropping collector, as employed for the determination of the potential of the air at fixed observatories, consists of a metal tank of water supported on an insulating stand and connected with one electrode of a quadrant electrometer, the other electrode of which is put to earth. A long tube, suspended by insulating strings, conveys the water from the tank to the point at which the potential of the air is to be measured. At this point the water is allowed to escape from a jet and break up into drops. If the potential of the tank is lower than that of the air at the point where the drops fall, each drop, being in connection with the conductor, will be negatively electrified, and in falling will carry off its negative electrification with it. This action will continue until the potential of the tank is equal to that of *the air immediately surrounding the drops at the point where they break away*, and when this is the case the drops will fall away unelectrified, and the potential of the tank will undergo no further change. The electrometer, therefore, will register the potential of the air at the point where the drops fall away from the jet; or, if a continuous stream of water fall for some distance, the potential registered will be that of the air where the stream breaks up into drops. If the tank be originally at a higher potential than the air at the point where the drops fall, the drops will be positively electrified until the potential of the tank has been sufficiently reduced.

In fixed observatories the water dropping collector is usually employed in conjunction with the quadrant electrometer, and the light reflected from the mirror of the electrometer is allowed to fall on sensitised paper, which is wrapped round the surface of a cylinder or barrel. The cylinder is caused to rotate by clockwork, and thus the position of the needle, and, therefore, the potential of the air, at all hours of the day is recorded.

In a previous paper we discussed the energy of a Leyden jar or battery. It is now desirable that we should endeavour to learn where this energy resides. We are justified in thus devoting special attention to the Leyden jar, inasmuch as it is the type of all electrified systems. Take, for example, a sphere suspended in the centre of an otherwise empty room,

Digitized by Google

and positively charged. There will be on the interior of the walls of the room a quantity of negative electrification numerically equal to the charge on the sphere, and thus the system will be equivalent to a Leyden jar in which the sphere serves as the inner coating, the walls of the room as the outer coating, and the air as the dielectric. No electrified system under consideration is complete unless we can in this way show it to be equivalent to a Leyden jar.

If a Leyden jar is so constructed that its inner and outer armatures (or coatings) can be removed by means of insulating handles, and if the jar be charged and then stripped of its armatures, the latter will be found to be almost unelectrified, but upon replacing them in their proper positions the jar can be discharged. If, instead of replacing the same armatures, a new pair of armatures were fitted to the jar, the discharge could be obtained with equal facility. This experiment indicates that the energy of the charged Leyden jar does not reside upon its armatures, but upon or within the glass itself.

When a Leyden jar is charged to a very high potential, a spark will sometimes pass through the substance of the glass, destroying the jar, and frequently pulverising the glass in the neighbourhood of the perforation. Before the glass can yield to the electric forces, it is clear that it must be strained beyond its elastic limits, and up to its ultimate strength. Hence we may conclude that before the jar is charged sufficiently for a spark to pass the glass must be in a state of strain. To produce this strain work must have been done, and the glass, like a bent spring, in relieving itself from this state of strain, is able to do an amount of work equivalent to that which has been done upon it (if its elasticity be perfect). We are thus led to regard the strained condition of the glass as the form which the energy of the charged Leyden jar assumes, and as all the electrified systems with which we are concerned in the study of electrostatics differ from a charged Leyden jar only in the nature of the dielectric and the forms and relative positions of the electrified surfaces, we naturally infer that the energy of all electrified systems is due to a state of strain of the dielectric, or insulator, which separates the oppositely electrified surfaces. According to this view the conductors in an electrostatic system simply serve to bring the electric charges to their surfaces. The dielectric is the arena of all electrostatic phenomena.

Faraday supposed that the particles of a dielectric in an electric field are thrown into a state of polarisation, each particle being electrified positively on one side and negatively on the other, and that in this way the electric force is communicated from point to point in the field. Maxwell showed that electric phenomena can be accounted for by supposing that there is a tension in the dielectric in the direction in which the electric force acts, accompanied by an equal pressure in every direction at right angles to the force, and that such a system of stresses is compatible with the equilibrium of the dielectric. The energy of the dielectric due to the state of strain into which it is thrown is the energy of the electrified system. The mechanism by which Maxwell supposed this state of strain to be brought about is consistent with Faraday's theory of polarisation.

When a Leyden jar is charged we must regard the glass as thrown into a state of strain, being exposed to a tension in the direction of its thickness, and an equal and opposite pressure at right angles to this direction. When the jar is discharged this state of strain is suddenly relieved, and the pent-up energy appears in the discharge.

When a glass fibre is twisted and then released it is found that it does not immediately return to its original state, but having nearly regained its original condition in the first rebound it afterwards returns only very slowly, so that a very long time elapses before the glass is in exactly the same condition as it was before the strain. Other (imperfectly elastic) substances exhibit similar phenomena in a more or less marked degree. The same behaviour appears in the discharge of the Leyden jar. The glass does not at once return to its original condition, and restore, in the first discharge, the whole of the energy employed in charging the jar. But if, after the first discharge, the jar be left for a time, it will be found possible to obtain a second discharge (much smaller than the first) from it, and after another interval a third discharge and so on, the discharges becoming successively feebler. The charge left in the jar after the first discharge is known as the "residual charge" of the Leyden jar.

All dielectrics do not allow of the transmission of electric force with equal facility. Thus, if two balls be charged so that they repel one another with a force of one dyne when separated by one centimetre in air, and if the balls be then placed in paraffin oil, the force between them will be considerably less than one dyne when they are at the same distance apart, and to obtain a repulsion of one dyne at a distance of one centimetre in paraffin oil the charges must be considerably increased. Hence, if we were to determine the unit of electricity by finding the amount which would repel an equal amount at a distance of one centimetre with a force of one dyne, and were to repeat our experiments in different media, each different dielectric would furnish a different unit, that obtained in air (or vacuum) being the least.

Since the forces between charges of electricity depend on the medium through which they act, it follows that the quantity of electricity required to raise a conductor to unit potential will depend on the nature of the dielectric which separates it from other conductors in the neighbourhood.

Def. The ratio of the capacity of a condenser having any given substance for its dielectric to that of an otherwise precisely equal condenser having air for its dielectric is called the specific inductive capacity of the substance.

The letters S.I.C. are sometimes employed as an abbreviation for specific inductive capacity.

The measurement of the specific inductive capacity of a dielectric is a very difficult operation, on account of the complications introduced by the phenomenon of "residual charge." The difficulty is greatest in substances which, like glass, are of very complex chemical constitution. To reduce as far as possible the errors arising from this cause attempts have been made to measure the capacities of the condensers when they are charged, and discharged successively many thousands of times in a second.

The title of Specific Inductive Capacity was invented by Faraday, who constructed two precisely equal condensers, each consisting of a sphere insulated within a larger hollow sphere, the latter having an aperture for the passage of the electrode of the inner sphere. Faraday first proved the equality of the capacities of the instruments when the space between the spheres was occupied by air, by charging one condenser, measuring its potential by Coulomb's torsion balance, then connecting it with the second condenser, and again measuring its potential, when it was found that the potential was reduced to one half of its former value. Hence the charge was reduced to one half, and the capacities of the condensers were therefore equal.

Faraday then half filled the space between the spheres in one condenser with shellac, charged the air condenser, and divided the charge between the two, after measuring the potential of the charged condenser. On again measuring its potential it was found to be reduced to about two-fifths of its former value. Hence the capacity of the shellac condenser was one and a half times that of the air condenser. From this Faraday inferred that if the whole space between the spheres had been filled with shellac the capacity would have been doubled, and he, therefore, concluded that the S. I. C. of shellac was about 2.

Faraday ("Exp. Res.," 1,252-1,317) attempted to measure the specific inductive capacities of several substances by means of the apparatus just mentioned. He came to the conclusion that all liquids and solids have a specific inductive capacity greater than that of air, but he could detect no difference between different gases or gases at different pressures.

The measurement of the specific inductive capacities of transparent dielectrics is of great interest in connection with Clerk Maxwell's electro-magnetic theory of light, for, according to this theory, the specific inductive capacity should be equal to the square of the refractive index of the medium "for light of infinite wave length" (ultra-red rays), in the

Digitized by Google

case of all substances whose magnetic permeability is sensibly equal to that of air. An account of some of the modern methods of measuring specific inductive capacity will form the subject of the next paper.

A GUIDE TO PRACTICE IN THE SUBMARINE CABLE TESTING ROOM.

No. XVII.

The insulation resistance of cables is usually determined by the method explained in Nos. IX. and X. We refer to the daily tests at the works, and to such as are taken under conditions when there is no disturbance, or as little as possible; for even in a factory testing room it is impossible to make such provision as will ensure a total absence of opposing interference of one kind or other. The causes which are likely to bring this about are various. The action of coiling a cable into or out of a tank in which, or in the immediate neighbourhood of which the cable under test is placed, or the transfer of the latter itself to another tank, which is sometimes necessary, and which need not prevent the performance of the operation, will cause electrical disturbance in the charged section. Vibration from the machinery will affect the cable, and thence produce irregularity in the galvanometer deflections. Atmospheric disturbance is not so common, though sometimes troublesome. The earth plates are occasionally the cause of trouble; local currents are set up which disturb the test circuit and confuse the observations; but it is chiefly at shore stations, during or after submergence, when cables are subject to the influence of earth currents, which on some lines are very powerful, so much so that it is impossible to get correct results by any method. Under these conditions the spot travels up and down the scale, wandering and swinging both ways even when the cable is not charged. Various devices have been adopted to counteract this disturbance, one or two of which we shall discuss by and by. It is not merely a matter of interesting inquiry, but one that is well worth looking into. The test now to be considered is known as that by loss of charge, the principle being that which underlies the charging qualities of cables regarded as condensers. There are various methods of making it, and the galvanometer or electrometer may be employed for the purpose. We are now concerned with the former of these instruments, and have two forms of test to explain in this number. A few preliminary remarks are necessary to give a clear impression of the meaning of the operation, and to show how the desired object is attained by the method in question. We have explained in a former paper what insulation resistance is, and what are its relations to the general properties and office of a submarine cable, and it is from a consideration of the various conditions and their bearing on one another that we are enabled to deduce a rule for estimating an unknown quality in any particular section from others that are known. It is in such examinations that the value of algebra as an aid is made apparent; fortunately, a comparatively slight acquaintance with it is sufficient, as we shall see when presenting the various formulæ governing the working out of all the tests.

As the learner knows, a cable, say in water, connected (with one end free in air) to a battery, one pole to the conductor and the other to earth, will receive a certain charge regulated by what is called the capacity of the cable, and by the potential of the battery. If the battery be now disconnected, the cable leaks, parts with its charge, which is said to discharge slowly through the insulating cover (its dielectric) to the water outside, in other words to earth. This is the familiar way of expressing the conditions. Of course the charge also escapes at the end, which is insulated from earth, but for our purpose we may neglect the consideration of this feature, and regard the leakage or loss of charge as from the outside of the whole surface of the conductor through the insulating sheath. Under these circumstances, the charge escapes at a certain definite rate. If five per cent. of the whole charge, that of full potential, escape in the first minute, then five per cent. of the *remaining* charge will be lost in the second minute and so on, following the rule of compound interest; this is the first point to be noted. In the next place, it must be remembered that what is called the capacity depends on the nature of the dielectric; all substances have their specific insulating quality, or, in other words, as we may put it, their conductive disability. The quality termed insulating resistance, when viewed in relation to the character of a cable, is a desirable property; it is the insulating resistance of a bad conductor. The specific resistance of dielectrics, such as gutta percha, india rubber, &c., is, then, a point of great importance in this connection, and though it is impossible to form an exact table of relative specific resistances for such substances, yet a sufficiently correct estimate has been made, and they have been tabulated on the ground of numerous experiments, from which we are enabled to calculate the different qualities of cables, as their capacity, resistance, &c. Air is taken as the standard, regarded as unity, and gutta percha, the usual dielectric for cables, is stated as 4·3. To explain this more clearly, as we observed just now, the capacity of a condenser, or a cable, regarded as such, depends on the quality technically known as the "specific inductive capacity" of its dielectric, the reverse of which is the (specific) inductive resistance. The higher the inductive capacity of a dielectric in a condenser the greater the charge which it will take. Having air as 1, and gutta percha as 4·3, an air condenser will take a charge of 1 as compared with 4·3 for the same condenser if gutta percha were substituted for it; therefore, in calculating or in comparing two such condensers, whatever value we might give to the capacity of that having air between its opposing plates must be multiplied by 4·3 to give the value of the capacity of the gutta percha condenser. This quadruple feature may be called a negative quality, for inductive *resistance*, and not capacity, is what is required in a dielectric.

A third point to be remembered in connection with the means for framing a rule to express the measurement of this insulation resistance is one that has been already mentioned. The potential of a charge in a condenser or a cable is represented by the deflection which it produces when passing through a galvanometer.

Summing up, we find that the insulation resistance can be determined by noting the difference of potential between any two periods of discharging the condenser (or cable), the time being carefully noted. Thus, if it be charged to a certain potential, and at once discharged, then again charged to the same potential, and be allowed to leak for, say, one minute, and again discharged, we can note the fall of potential by the comparison of the two deflections; then, supposing the capacity to be previously known, we have the conditions for calculating the insulation resistance. From these a formula has been constructed which will be more fully explained further on, but which is based on the facts which we have noted. The rate of leakage, and, therefore, of the fall of potential, as shown by the discharges, follows the rule of compound interest which determines the value of the ratio or comparison of the two deflections to be a logarithmic sum, and not a simple (or natural) numerical value. Without going into the working it may be as well to write the formula here, since it is possible the learner may not be quite sure about it, as he may meet it under two different forms in different text books. It is usually given thus—

$$R = \frac{26{\cdot}06 \times t}{F \times \log \frac{P}{p}},$$

signifying that the insulation resistance of a cable tested in this way is equal to, or measured by, 26·06, multiplied by the time in minutes between the first and second (or first and third, &c.) deflections, and divided by the capacity of the cable in microfarads multiplied by the logarithm of the ratio of these deflections, the result being in megohms. The value 26·06 is merely the product of the 60 seconds in a minute, and the coefficient expressing the difference between two different systems of logarithms. If the formula be written with the time in

Digitized by Google

seconds, and the *Napierian*, or natural system, it will be $R = \frac{t}{F \times \log_{\epsilon} \frac{P}{p}}$, which in the common, or *Briggean* system, is $\frac{\cdot 4343 \times t}{F \log \frac{P}{p}}$, and $\cdot 4343$ multiplied by $60 = 26 \cdot 06$ as nearly as possible.

There are several tests on this principle, that is, the fall of potential being observed in different ways, or rather, for different periods. Some electricians prefer to note the time in which a cable falls to half potential, and this again is determined in various ways. We are commencing with the comparison of potentials at intervals of from one to five or ten minutes, using the galvanometer for the purpose. We may observe here that the electrometer enables us to watch the actual fall of potential; it is as if we could see into the interior of the cable and notice what is going on. With the galvanometer we can only observe the potential from time to time, and estimate the rate of fall by comparison of the deflections. The test may be made either by charging or discharging the cable; that is to say, instead of noting the fall of potential by the discharge of what remains after the minute's leakage, we can let the cable leak for the fixed time and then recharge, the deflection resulting from which operation will represent the amount of charge necessary to replace what has escaped. In this case the full potential is shown by the deflection got

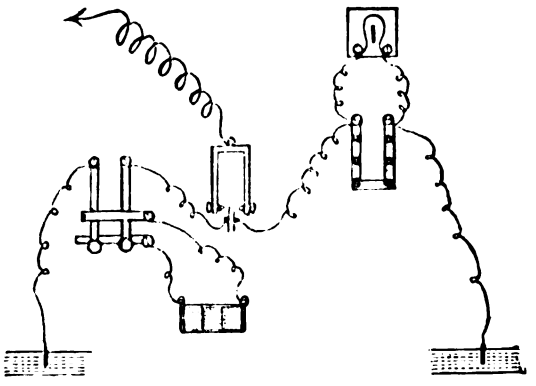

FIG. 39.—Insulation Resistance (Discharge Test).

by charging through the galvanometer in place of discharging as in the other form. The connections for the discharge test are shown in Fig. 39, and are very simple. The Lambert key connects by one front terminal with the battery key and the other with the galvanometer, the end terminal joining up with the cable which is supposed to be insulated at the further end (where the arrow points).

A few words on the comparison of the two operations, the charge and discharge tests, may serve to remove any difficulty that may be felt on the subject. The conditions appear to indicate that something very different in each case is being done. When the "discharge" test is taken in the manner we have suggested, the reduced potential in each succeeding deflection is compared with or related to the full potential or sudden discharge, technically speaking, so that each reading represents a different potential, namely, that of the charge at the particular instant. In the "charge" test, after taking the reading for full potential, the succeeding deflections are the result of a proportion of the charge sufficient to make up for that which has been lost by leakage through the dielectric. In the first example the full charge passes through the galvanometer at first, and afterwards a less amount at each succeeding discharge. In the second example, the full charge also passes through at first, but afterwards more at each repetition, and only enough to fill up the loss. The two cases are reconciled, so to speak, by a slight variation in the working out. The charge test is worked out (by an obvious calculation) so as to give us the discharge that would have resulted if it had been taken in the other way. It is assumed, indeed it is regarded as a fact, that charge and discharge are always equal; that is to say, a perfect cable shows the potential to be the same whether we measure by one or the other. A charge from a given number of cells produces the same deflection in passing through the galvanometer whether entering or leaving the cable.

(TO BE CONTINUED).

BALL'S UNIPOLAR DYNAMO.

At the invitation of Mr. C. W. Raymond, who has charge in England of the interests of the company owning this machine, we recently inspected the unipolar machine at work. Before describing the machine, we may, perhaps, refer to Mr. Sabine's report, a copy of which has been sent to us, and which is as follows:—

3, Great Winchester-street, London,
20th March, 1883.

Chas. Ward Raymond, Esq.

Sir: According to your instructions, I have tested the continuous current dynamo-electric machine of Mr. Ball, at present at 41, Kirby-street, Hatton-garden. This machine consists of a long rectangular frame of soft iron, coiled so as to form the field magnets, and which longitudinally supports the axes carrying two bobbins of the Pacinotti type. The main peculiarity of the machine is that each bobbin is rotated in the presence of only one magnetic pole, the opposite side of the bobbin facing a neutral point of the field. Hence the name "unipolar," by which the inventor designates his dynamo. The effect of this so-called unipolar arrangement, in so far as the field is concerned, appears to be that the rectangular soft-iron frame is converted into two long electro-magnets with two poles, only one being presented to each of the rotating bobbins, instead of four shorter, and proportionally weaker, electro-magnets having four poles, as in the ordinary way, by which two opposite poles would be presented to each of the bobbins.

When I tested the system, the dynamo was run with six arc-lamps, also said to be of Mr. Ball's invention, the dynamo being worked on the "series" system, that is to say, field magnets, armatures, and lamps all joined up in series. The speed of the machine was not so regular as could have been desired, and the Morin dynamometer, by which the power given to the dynamo was measured, would have worked steadier had it been driven quicker or with a heavier load.

The following are the mean results which I found:—

Current in circuit = C = 15·0 amperes;

Potential difference between terminals = E = 195 volts;

Resistance of dynamo = r = 4·5 ohms;

Speed of dynamo, 1,650 to 1,715 revolutions per minute;

Speed of dynamometer = s = 332 revolutions per minute;

Indicated pull on dynamometer, less pull when circuit open } = k = 52 kilo.

From these values,

1. Given to dynamo for electrical work,
$$\frac{1 \cdot 5\ k\ s}{60 \times 76} = 5 \cdot 68 \text{ h.-p.}$$
2. Accounted for in outer circuit,
$$\frac{E\ C}{746} = 3 \cdot 92 \text{ h.-p.}$$
3. Accounted for in inner circuit,
$$\frac{c^2\ r}{746} = 1 \cdot 35 \text{ h.-p.}$$

The proportion accounted for electrically, therefore,
$$\frac{5 \cdot 27}{5 \cdot 68} = 0 \cdot 92,$$
of which $\frac{3 \cdot 92}{5 \cdot 68} = 0 \cdot 69$ was accounted for in the lamps. This would leave only 8 per cent. for the so-called Foucault currents.

Photometric measurements were made with one of the

Digitized by Google

lamps, placed apart from the others in a dark recess, the light of the five remaining lamps not being measured.

The following mean results were obtained during the observations:—

Current in lamp = 13·9 amperes.
Potential difference = 40·1 volts.

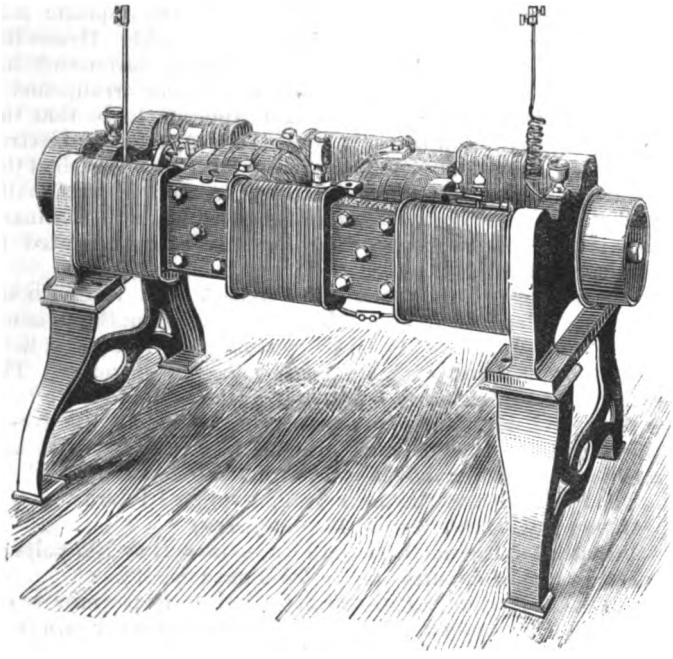
Accounted for in lamp $\frac{13{\cdot}9 \times 40{\cdot}1}{746} = 0{\cdot}75$ h.-p.

The illuminating effects were as follow:—

Position of arc with regard to photometer.	Illuminating power.	
	Observer.	Per 1 h.-p. accounted for in the lamp.
	Standard Candles.	Standard Candles.
22° below	602	802
11° below	626	835
Horizonal	887	1,183
11° above	1,213	1,617
22° above	1,831	2,441
31° above	1,859	2,479
35° above	1,690	2,253

(Signed) Yours faithfully, Robert Sabine.

The figures given in this report are very similar to those obtained by us, except that we made no photometric measure-



Pall's Unipolar Dynamo.

ments. The number of revolutions per minute varied slightly around 1,700, the horse-power as indicated by the dynamometer was about 5·25 with the six arc lights in circuit. The lights were steady, and the machine seemed to heat very little. The time during which our observations extended, however, was too short to prove anything with regard to heating, but on general grounds we should expect such a machine to run cool. The accompanying illustration will show better than mere explanation can the type of machine designated as "Unipolar." It has two armatures, each 8in. in diameter, revolving in opposite directions. Each armature contains 60 sections of wire, wound as in the Pacinotti or Gramme rings, the commutator also having 60 sections. The wire is No. 14 (Am. gauge), of copper, weighing about 19lb. on each armature, or about 38lb. on the two. The field magnets are wound with No. 8 (Am. gauge), copper wire, the weight being about 130lb., the total weight of wire thus being about 168lb. In the more recent machines we are informed much less wire is used, there being in the above machine an excess of something like 35 per cent. The driving power is conveyed by two belts, each ·5in. wide, running over 8in. pulleys. The size of the magnet bar is 7in. by 1·125in. The following details are obtained by advices from New York of an improved five-light machine on this principle:—The total weight of copper on field magnets and armature is about 88lb., the total weight of the machine being altogether about 350lb., or about 70lb. per lamp. The number of revolutions in this machine for the five lamps is 1,190 per minute. In this machine also there are two armatures with but one pole piece to each armature and but one commutator on one shaft. These revolve in the same direction, one belt only being used. In this machine while the armature still has sixty sections the commutator has a hundred and twenty. The internal resistance is 2·6 ohms.

Another machine of this type that has been built is a 15-light machine, with two armatures, each 12in. dia., containing about 3,000ft. (80lb.) of No. 14 wire. It has six magnet bars, each 2in. by 2in., three at top and three at bottom, containing about 4,444ft. (200·5lb.) of No. 8 wire. The total weight of this machine is about 997lb., or 66lb. per lamp; made up thus:—

As above	280·5lb.
Iron	661
Commutators (Cu)	30
Bearings (composite)	26
	997·5lb.

The internal resistance of the machine is given as 7 ohms. With a periphery speed = 3,600ft. per minute = 1,146 revolutions, current is supplied for 15 arc lights.

The six-light dynamo reported upon by Mr. Sabine, and seen by us, is said to have been running in New York or London during the greater part of twelve months—and has had no repairs. It was taken to pieces, cleaned, and painted prior to shipment, otherwise no work has been expended upon it.

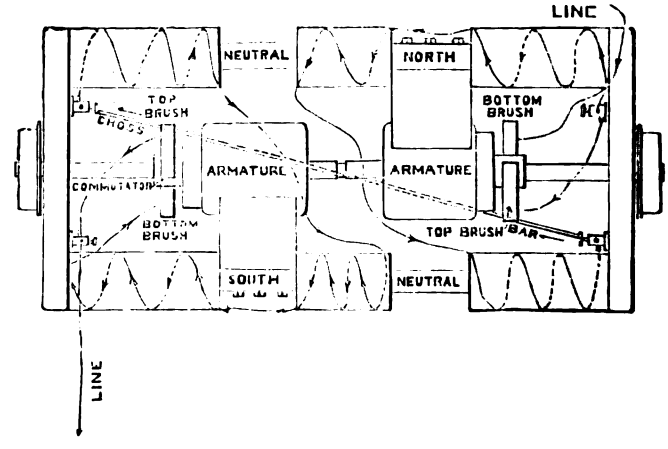


Diagram showing Method of Winding, and the Connections.

The accompanying diagram shows the method of winding, and the connections.

It is difficult to express an opinion as to the merits of this machine, as at first sight it seems to be the opposite of wise to drive an armature through a complete revolution and cut lines of force only once, when, as in the Gramme machine, opposite sides of the armature may be used, of course with two poles. Experiments are said to have been made to compare the effects obtained with those obtained in a bipolar machine, and the result was in favour of the unipolar. We shall be interested in the details of such experiments.

INTERNATIONAL ELECTRIC EXHIBITION, VIENNA.—We have been officially informed that the Austro-Hungarian railways will grant a reduction of from 70 to 80 per cent. in the freight on all objects sent to the Electric Exhibition at Vienna. This reduction will relate equally to the transport of goods to and from Vienna.

REIS'S TELEPHONE.*

The following is a copy of an autograph description of Reis's telephone, which has been presented to the library of the Society of Telegraph Engineers and of Electricians by Mr. William Ladd, member:—

[Copy.]

Institut Garnier, Friedrichsdorf.

Dear Sir: I am very sorry not to have been in Francfort when you were there at Mr. Albert's, by whom I have been informed that you have purchased one of my newly-invented instruments (telephons), though I will do all in my power to give you the most ample explanations on the subject. I am sure that personal communication would have been preferable, specially as I was told that you will show the apparatus at your next scientifical meeting, and thus introduce the apparatus in your country.

Tunes and sounds of any kind are only brought to our conception by the condensations and rarefactions of air or any other medium in which we may find ourselves. By every condensation the tympanum of our ear is pressed inwards, by every rarefaction it is pressed outward, and thus the tympanum performs oscillations like a pendulum. The smaller or greater number of the oscillations made in a second gives us, by help of the small bones in our ear and the auditory nerve, the idea of a higher or lower tune.

It was no hard labour, either to imagine that any other membrane beside that of our ear could be brought to make similar oscillations, if spanned in a proper manner and if taken in good proportions, or to make use of these oscillations for the interruption of a galvanic current. However, these were the principles which guided me in my invention; they were sufficient to induce me to try the reproduction of tunes at any distance. It would be long to relate all the fruitless attempts I made until I found out the proportions of the instrument and the necessary tension of the membrane. The apparatus you have bought is now what may be found most simple, and works without failing when arranged carefully in the following manner:—

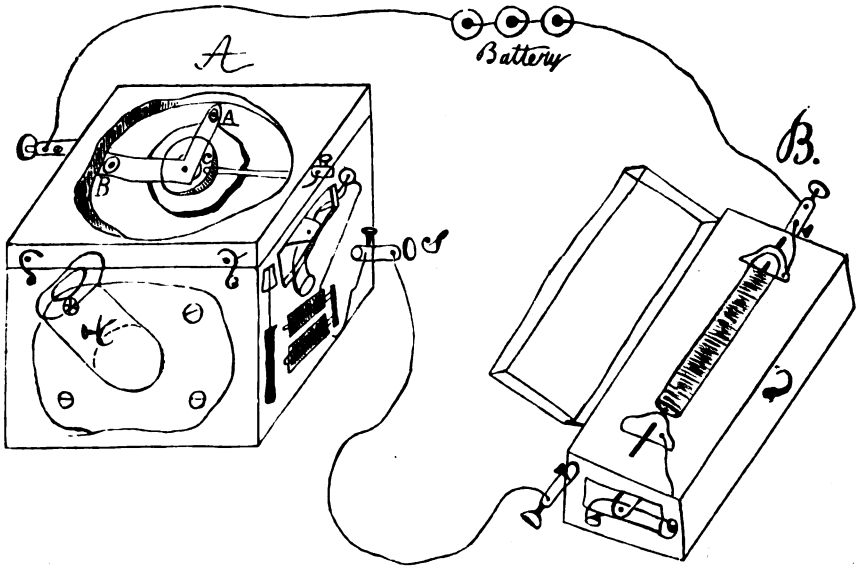
The apparatus consists of two separated parts, one for the singing station A, and the other for the hearing station B.

The apparatus A is a square box of wood, the cover of which shows the membrane *b* on the outside, under glass. In the middle of the latter is fixed a small platina plate, to which a flattened copper wire is soldered, on purpose to conduct the galvanic current. Within the circle you will further remark two screws; one of them is terminated by a little pit in which you put a little drop of quicksilver, the other is pointed. The angle, which you will find lying on the membrane, is to be placed according to the letters, with the little hole *a* on the point *a*, the little platina foot *b* into the quicksilver screw, the other platina foot will then come on the platina plate in the middle of the membrane.

The galvanic current coming from the battery (which I compose generally of three or four good elements) is introduced at the conducting screw near *b*, wherefrom it proceeds to the quicksilver, the movable angle, the platina plate, and the complementary telegraph to the conducting screw *s*. From here it goes through the conductor to the other station B, and from there returns to the battery.

The apparatus B, a sonorous box, on the cover of which is fixed the wire spiral with the steel axis, which will be magnetic when the current goes through the spiral. A second little box is fixed on the first one, and laid down on the steel axis to increase the intensity of the reproduced sounds. On the small side of the lower box you will find the corresponding part of the complementary telegraph.

If a person sing at the station A, in the tube *x*, the vibrations of air will pass into the box and move the membrane above, thereby the platina foot *c* of the movable angle will be lifted up, and thus will open the stream at every condensation of air in the box. The stream will be re-established at every rarefaction. In this manner the steel axis at station B will be magnetic once for every full vibration, and, as magnetism never enters nor leaves a metal without disturbing the equilibrium of the atoms, the steel axis at station B must repeat the vibrations at station A, and then reproduce the sounds which caused them. Any sound will be reproduced if strong enough to set the membrane in motion.



Reis's Telephonic Apparatus.—Facsimile of Drawing sent by Reis to Mr. Ladd.

The little telegraph which you find on the side of the apparatus is very useful and agreeable for to give signals between both of the correspondents. At every opening of the stream, and next following shutting, the station A will hear a little clap, produced by the attraction of the steel spring. Another little clap will be heard at station B in the wire spiral. By multiplying the claps and producing them in different measures, you will be able, as well as I am, to get understood by your correspondent.

I am to end, Sir, and I hope that what I said will be sufficient to have a first try; afterwards you will get on quite alone.

I am, Sir,

Your most obedient servant,

Friedrichsdorf, 13/7/63. Ph. Reis.

To Mr. William Ladd.

THE ELECTRICIAN.

TO CORRESPONDENTS.

All letters intended for insertion in THE ELECTRICIAN, *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

All communications to be addressed to 396, *Strand, London, W.C.*

We cannot undertake to return drawings or manuscripts, and must, therefore, request Correspondents to keep copies.

ANSWERS TO CORRESPONDENTS.

X. CLARK (BOSTON).—*So far as we know there is no work published dealing specially with the subject you mention. You will find information on the subject in the tariff book of the Eastern and other Cable Companies, and also in articles by Sir J. Anderson, together with correspondence arising therefrom, published in the early numbers of* "THE ELECTRICIAN."

J. L——R (GAINSBOROUGH).—*Write to the secretary, City and Guilds of London Institute, Gresham College, E.C., who will give you every information. The Central College you refer to is, we believe, in connection with the Institute, but we doubt if it is yet ready for actual work; perhaps you were thinking of the College at Finsbury. Information concerning both can be obtained from the same source.*

E. G. DORNBUSCH.—*You will find something referring to the paragraph about a "Remarkable Electrical Discovery" in our Notes this week.*

A. R. E. A.—*We must call your attention to Ohm's law,* $C = \frac{E}{R}$. *Now* E *being fairly constant,* C *will depend upon the external and internal resistances you may have. Then, again, do you want the current for one second or for a long period? We should have imagined that any elementary book, such as Ferguson, would give you the information you require.*

J. P. (GLOUCESTER).—*The particulars you ask for are to be found spread about in various periodicals, but, so far as we know, are not to be found in a collective form. The transmitters are, we believe, patented.*

A LOVER OF LIGHT.—*We cannot insert your letter unless you send your name and address, though these need not necessarily be published. We are afraid that, though very well as an exhibition, the mode of lighting which you describe is hardly practicable. Americans are certainly celebrated for "big things," but we doubt if they will ever light a town, even a village, properly, by means of one powerful arc light. You forget the shadows thrown by houses. Light, to be of use, must be distributed.*

REIS'S TELEPHONE.

The *Journal* of the Society of Telegraph Engineers, which for some time past has been the subject of much complaint on account of both the quality and quantity of its contents, is this month redeemed from insignificance by the appearance in its pages of a copy of a letter addressed to Mr. Wm. Ladd, and bearing date 13th July, 1863, from Ph. Reis, explanatory of his telephone, accompanied by a fac-simile drawing from the same hand. We could have wished the epistle fac-similed as well as the diagram, for then the lettering would have agreed in both, which is not the case as they now stand. But, allowing for this defect, we may thank Mr. Ladd and the society of which he is a member for contributing this interesting and important piece of evidence on a matter which has lately given rise to so much doubt and disputation.

We have reproduced both the letter and the diagram in another column just as we find them in the *Journal*, and it should be understood that the remarks we are about to offer upon them are subject to possible correction, either from the receiver of the letter, who, having purchased a specimen of Reis's apparatus, understands it, no doubt, better than any one who has only the drawing and explanation to guide him; or from it happening that the fac simile is not quite accurate in every detail. Reis evidently knew how to draw, and, although he has made a blunder here and there excusable in a rough sketch, the figure as a whole is clear and accurately pencilled. On this account we are inclined to suspect the fac simile rather than the original draughtsman of one serious defect to which we shall draw attention presently. We must, however, take the drawing as it stands for the purpose now in hand.

As regards the letter its obscurity is unavoidable. Mr. Ladd would have added much to the favour he has conferred in publishing Reis's letter if he had supplemented it with an explanation in good English—that is to say, told us what *he*, by the light of the instrument itself, understood its inventor to mean in certain passages, which, owing to Reis being a foreigner, are open to diverse interpretations. At a first reading all seems tolerably clear, but directly we try to follow the description by means of the drawing matters get confused, and on one or two vital points we are left in utter uncertainty. On the other hand, the diagram disabuses us of the startling impression created by first perusal of the letter:—"The angle, which you will find lying on the membrane, is to be placed according to the letters, with the little hole *A* on the point *A*, the little platina foot *B* into the quicksilver screw; the other platina foot will then come on the platina plate in the middle of the membrane." Here a point dipping into a mercury cup on a membrane at once suggests the solution of the whole problem; but, in reality, it is nothing of the sort. If the quicksilver had been in the middle of the membrane its object might have been open to another construction, but being where it is the purpose it actually serves is only to make good contact where the current enters at *B*.

This being so we may fix our attention on the centre of the box A. We confess our inability to follow the text of the description:—"The cover shows the membrane *B* on the outside, under glass." This is sufficiently confusing; what follows is still more so:—"In the middle of the latter is fixed a small platina plate to which a flattened copper wire is soldered, on purpose to conduct the galvanic current." According to this the uppermost platina plate is affixed to the glass cover; this, indeed, may be so, but in the diagram the flattened copper wire—which we take to be represented by the narrow strip running from near *C* in a right hand direction—is *not* soldered to anything. It is drawn as passing under the plate, and its blunt end terminates in space. A further complication arises through the presence of

Digitized by Google

a small circle indicated in the centre beneath the elbow angle of *A, B*. But for the word "small" being applied to the upper plate this lower circle might be mistaken for the plate on the membrane. We can only infer that it is some detail redundant for the essential object though present in the apparatus.

We may take it, therefore, that "the platina plate in the middle of the membrane," and upon which rests the central "foot," is represented by the circle whose ragged outline passes *under* the "angle" as well as under the strip of copper. It may, however, represent merely the outline of the membrane. In fact, if we follow the text and the picture, trying to reconcile the two, we may conceive either that the membrane is below the "angle" or above it, that the smaller platina plate is affixed to it or is held rigid and independent. Further, it may be that the current is normally permanent, or is normally broken. In short, after giving the arrangement every attention possible, we find that its essential feature is not in these details at all, is much simpler, and at the same time much less efficient than we had imagined. We, of course, refer to the transmitter; the receiver has striking merits of its own, which, however, not being now in question, need not be discussed.

Now, what is the essential feature of this telephonic transmitter? We have no hesitation in answering, as, indeed, we have answered many times before, that it is a make and break contact, capable of transmitting musical tones, but unreliable for reproducing articulate speech. If any doubt remain as to this, let the reader turn to the last paragraph but two of Reis's letter:—"If a person sing . . . . the vibrations of air will pass into the box, and move the membrane above, thereby the platina foot *C* of the movable angle will be lifted up, and thus will open the stream at every condensation of air in the box." In the next sentence we are told, "the stream will be re-established at every rarefaction;" and in an early part of the letter he speaks more explicitly of using the oscillations of a membrane "for the interruption of a galvanic current." His diagram corroborates the language he employs. Doubtful as are the relative positions of the parts, there is no doubt whatever as to their action. A platinum point is made to oscillate so that once in every "full vibration" of a membrane a galvanic current is established. This is what the letter and the diagram tell us—this and nothing more.

Reis himself makes no claim in his letter to being able to transmit speech. He calls the transmitting station "the singing station," and in describing the mode of procedure he uses the words, "If a person sing." Elsewhere he has spoken with seeming disappointment, or rather with puzzled surprise, that the receiver failed to reproduce the vowels satisfactorily. This, according to the extract printed in our columns on the 10th inst., at page 394, was in the year 1860-61. The letter we are discussing bears date 1863. It would be difficult to discover in what respect the instrument we have been describing was superior to that of two years earlier date. The later one we may assume was the perfected instrument; it could not speak except by fortuitous accident. This was admitted though the reason was not known. But *we* know the reason, and knowing it we know also how to make Reis's contrivance do more than he was able to make it do; but not much more. To use his own words, it can only be trusted for the "reproduction of *tunes* at any distance."

It is agreeable to turn from the purely negative part of our task, in order to express our admiration of Reis's conception of the problem he had to solve. On this point the second paragraph of his letter is most interesting. Whether he was completely master of the conditions upon which sounds are communicated to the auditory nerve cannot be determined with certainty on the evidence of a brief letter of this kind; but as regards the conditions for reproducing them electrically we see plainly enough that he was within very measurable distance of complete mastery. Those who have followed him, and have succeeded where he failed, have ungrudgingly acknowledged his great merits; at the same time, they may, perhaps, be pardoned for pointing out that, so far as appears from the evidence yet adduced on his behalf, Reis did not succeed in transmitting articulate speech by electrical currents, and that he never could have succeeded with the transmitter he was using down to the date of his letter to Mr. Ladd. He might have succeeded with his *receiver*, but that is quite another matter.

CORRESPONDENCE.

ELECTRICAL ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In a commercial country one is accustomed to excuse and to pass without comment a large amount of "tall talk" in connection with wares that are offered for sale. But some of the remarks of Sir Daniel Cooper, at the annual general meeting of the Electrical Power Storage Company (Limited), of which a report appeared at p. 454 of your last issue, appear to me somewhat to overstep the prescribed latitude. In regard to the Brush Accumulator patent, Sir Daniel is reported to have said that "They had consulted some of the best authorities, and they thought there was very little in it. If an attempt were made to work it here, the Electrical Power Storage Company would immediately step in and take steps to stop it." Now, in more senses than one, there is a *great deal* in the Brush Accumulator patent; and I, for one, should be glad to know the names of the "best authorities" who hold the contrary opinion. Then surely Sir Daniel should be aware that any steps his company might take, *directly*, to stop the working of the Brush patent in this country would be perfectly futile, if not disastrous. Such working could no doubt be legally restrained, but not in virtue of any patents held by the Electrical Power Storage Company (Limited). The next statement of Sir Daniel must, no doubt, have had a very telling effect upon the shareholders of his company; but its audacity is simply amusing to those who know practically what has been done and what remains to be done in connection with secondary batteries, or to those who have made a study of the literature of the Patent Office in connection with these appliances. "As far as they knew," said Sir Daniel, "there was really no accumulator whatever, except their own, that was of any commercial value, and, as far as they could ascertain, other accumulators which were talked about were worthless commercially." The means of ascertaining possessed by the Electrical Power Storage Company would certainly appear to be of a most limited character. Of their own battery—to which, as well as to the strenuous and meritorious endeavours made to perfect it, I am anxious to render ample justice—it may be said that it is a very decided improvement upon that of Faure; and it may further be said, in relation to the patents by which it is guarded, that fatal mistakes in electro-chemistry, such as would invalidate every claim, have, in this case, generally been avoided. But to regard this battery, in its present form or as constructed in accordance with the patents just referred to, as the best of those which are, even at the present moment, available, is a mistake which is likely to be confined to those in whom "the wish is father to the thought." Sir Daniel may be excused for not having sufficiently entered into comparative experimental trials; but he surely must be aware, from what has been stated in the most influential journals which have considered the question of secondary batteries, that his own

Digitized by Google

opinion as to the exclusive merits of his company's accumulator are by no means universally entertained. Thus *The Times*, in its article of the 14th instant, after cautiously stating that "the Faure-Sellon-Volckmar accumulator is said to be free from the old objections," gives a very plain intimation that the best results are to be looked for in another direction. "Other inventions," says *The Times*, "have produced the lead in a finely-divided powder (*as a mass of interlaced crystals* would be a more correct description), and by compressing this powder into a compact mass they have obtained sheets of very porous lead. The rapidity with which accumulators made of this material can be 'formed' is remarkable, and those who have made experiments on these plates find them superior to any others." It seems then, that after all the excitement which was raised about the Faure battery we are likely to return "eventually to a form which resembles a Planté secondary battery to a much greater extent." In the leading technical journal the same opinion has been much more forcibly expressed.* The truth is, though the fact may be unknown to Sir Daniel Cooper and to the shareholders in his company, that in several directions important advances have been latterly made—by means of continuous experimental work, accompanied with the *minimum* amount of talk—in the construction of secondary batteries. The criticisms of Mr. Edison, and the objections which have hitherto been fairly applicable to all the forms of secondary battery, will, I venture to affirm, soon be out of date. An experimental acquaintance with secondary batteries extending over more than twenty years may, perhaps, enable me without presumption to hazard an opinion on this point.—Yours, &c.,

DESMOND G. FITZGERALD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should like to be told *on very good authority* that Mr. Edison, and others of his way of thinking, are mistaken, and also that what was written by me so long ago as December, 1881 (and on a Christmas Day, too!), does not apply to such secondary batteries as may be obtained at the present time; for I must confess that I have not yet seen enough to warrant my indulging even in the hope that what we generally hear in favour of them is true.

1. What is the average life of the very best accumulators of the day?

2. What is the actual first cost of them per electrical indicated power?

3. What is the cost of keeping them in the most efficient state?

Perhaps some of your readers who have neither invented, made, nor sold, any of these accumulators, but who—after buying and trying to work a few of them—have learnt something of their little ways, will give us the benefit of their experience, and so help to answer the questions asked above.

In many cases accumulators will be found very convenient—no sane man doubts this—but will they ever be cheap?

A few right-minded, but not altogether disinterested, people would have us believe that electric lighting with accumulators is Heaven, that without them it is—well—another place; that nothing can save us but faith and lead plates. When we ask for proofs we are told to think of the comforts accumulators bring with them, and to believe!

Now, such preaching as this may be all very well in its way, but too much of it is apt to interfere seriously with the spread of electric lighting, and I fancy that the time has come when the public might be trusted with the truth. Tell us what we must pay!

Poor "Chabot's Ghost" has caught my name, but not my meaning. The man who does not believe in accumulators is to be pitied almost as much as the one who believes that they are perfect, that they are cheap, and that it is impossible to do without them.—Yours, &c., $\frac{W}{g} \cdot \epsilon^{\gamma}$.

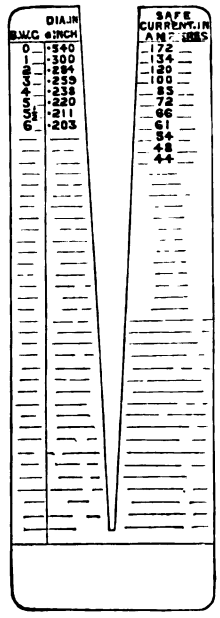
Ty-yr-dyn-gwyllt, the Feast of St. Ananias, 1883.

* *Vide* the *Engineer*, January 5, 1883, p. 14.

A GAUGE FOR ELECTRIC LIGHT ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I send herewith a sketch of a new gauge I have devised for the use of electric light engineers, &c., and which could be constructed by a steel rule maker in quantities at a very nominal rate.



Volk's Gauge for Electric Light Purposes.

On the obverse are columns showing size B.W.G., from 0 to 24, increasing by ½, diameter in inches, and safe current in amperes on the reverse, resistance per 100 yards 96 per cent. conductivity and weight per 100 yards.

The sketch is full size. The thickness should not be less than ⅛".—Yours, &c., M. VOLK.

Ditchling Rise Telegraph Manufactory,
Brighton, March 19, 1883.

THE ELECTRICAL POWER STORAGE COMPANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the report in your last issue of a few observations which fell from me on the subject of "Electrical Accumulators" at the recent meeting of the Electrical Power Storage Company an error occurs which, though abstractedly of small importance, I should be glad to have corrected, lest those who have known what my views have been on the subject referred to may think that circumstances have occurred which have caused me to alter or to modify them, the fact being that any difficulties which have intervened to delay their immediate or rapid fulfilment have only served, by the experience gained, to enhance my most sanguine expectations of the ultimate results that may be attained. The words I refer to were, "That I did not think it was *difficult* to realise in the near future the working of machinery, of railways, and of steamers by the aid of that power" (electricity). By the substitution of the word *possible* for *difficult* the tenour of my remark is completely altered.—Yours, &c.,

JOHN S. SELLON.

The Hall, Sydenham, S.E., March 27th, 1883.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We notice in the report in your issue of the 24th inst. of the annual general meeting of the Electrical Power Storage Company that the chairman mentions the various firms who have been supplied with accumulators. May we beg to call your attention to the fact that we received the first set of the Faure-Sellon-Volkmar accumulators sent to Scotland, and have since had them in daily use in exhibiting the electric light in our office here; and, further, we lent

Digitized by Google

them to Professor Ayrton for his lecture on "Electrical Locomotion" at the St. Andrew's Hall, Glasgow, on the 8th February last.

Had none of the other firms using accumulators been alluded to we would not have trespassed on your courtesy to correct the omission of our names.—Yours, &c.,

NORMAN and SON,
Electric Light Engineers,
per Alex. Grant.

Glasgow, March 27th, 1883.

WHAT'S IN A NAME?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to names, titles, &c., I need hardly ask your opinion of the title chosen and adopted by the "Society of Telegraph Engineers and of Electricians," because you have expressed it in your leader of January 27th.

Why seven words should be required to explain the nature of this society when two words would do equally well has always mystified me.

A quarter of a century ago, when electricity was in obscurity, one might have understood why such a long title was used, but in these days electricity is by no means obscure; it bids fair to be the most prominent and important science of our day, and this society promises to be ere long one of the most influential and powerful societies in the world. It is a pity, then, that its name should spoil it.

We have our Geographical, Geological, Meteorological, and other societies. Might I suggest "Electrical Society" as a name for the society to consider. So far as my knowledge goes "Electrical" covers *everything* in which electricity plays a part.

Some day, perhaps, "Royal" may be prefixed to the title. "Royal Electrical Society" would *look* and *sound* well, but fancy "Royal Society of Telegraph Engineers and of Electricians!!!"—Yours, &c., BREVITY.

SIEMENS'S SHUNT DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As I am making a small Siemens shunt dynamo, I should be much obliged if you would tell me—(1) How is ebonite made, or would boxwood be a good enough insulator for the commutator? (2) How to wind a Siemens dynamo? What thickness of wire should be laid on the field magnets? Their section is 6 × ¼-inch. (3) I propose winding the armature with four different series of coils (using four commutators), and, therefore, propose to wind the field magnets with four coils. Would there be any loss from induction?

Apologising for the length of this letter—Yours, &c.,

F. S.

THE MAKING OF GUTTA PERCHA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. W. H. Harrison, who writes in your last issue for information on the above subject, I may say that in a series of Cantor Lectures, delivered by Mr. Thomas Bolas before the Society of Arts in February, 1880, your correspondent will find a full description of the india rubber and gutta percha industries. These lectures were published in the *Journal of the Society of Arts*, which can be obtained at the society's office, Adam-street, Adelphi, W.C., and were also printed in *The Electrician*, Vol. V.—Yours, &c.,

WILLIAM H. PARKER.

Acton, W., March 28, 1883.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending March 23 were £2,133, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE ELPHINSTONE-VINCENT DYNAMO.

An exhibition trial of this machine took place on Wednesday, March 21st, and was of considerable interest. In addition to the trial of machines, Mr. Vincent delivered an address. The dynamo shown was one stated to be able to supply the current for 400 Swan 20 candle-power lamps. The motor was one of Mr. Rigg's patent high-speed engines, fitted, as the initiated of our readers know, with piston valves. The engine worked well, and among other attractions the fly-wheel fitted to the engine was not the least conspicuous. The following figures relating to the engine will be interesting:—Cylinder, 12", with 20" stroke; steam pressure, 80lb.; ¼ cut off with all lights on; ⅛ cut off during rest of the time. The Swan lamps wired for the purposes of the exhibition consisted of about 330 45-volt lamps, requiring under normal conditions 1·32 ampere. These lamps were hung on a kind of gridiron in one of Messrs. Unwin's upper warehouses, then 20 lamps were put into the engine room, 18 in the dynamo room, and about 15 more scattered about the building, making a total of 384 lamps. The lamps were arranged 2 in series, thus giving 192 circuits, and as each circuit required 1·32 ampere the total current required was 192 × 1·32 = 253·44 amperes. In addition to the 45-volt lamps, 25 high resistance 94-volt lamps had been fitted in the offices and shops in single multiple arc, each lamp requiring about ·66 ampere, or 25 × ·66 = 16·5 amperes altogether. When the machine was first started the high resistance lamps and about 40 others were run, and the former lamps being on separate leads it was found (using an Ayrton and Perry ammeter) that the result with 17 amperes current was very good. Upon the arrival of the visitors the remaining lamps were gradually put into the circuit about 100 at a time, and then the machine began to have its work cut out. Although we were unable to get figures relating to speed it was quite certain that the speed was largely increased. The current required for all the lamps would be about 270 amperes, at an E.M.F. of from 90 to 94 volts. Judging from the appearance of the lamps when the whole 409 lamps were in circuit we should infer that this number was somewhat too large for the capacity of the machine, and we think we may safely say that instead of 1·32 the current might be about 1·1. The maximum speed was stated to be not more than 950 revolutions per minute. The maximum speed and number of lamps was not continued the whole evening, in consequence of the excessive vibration, but about 150 lamps were kept in circuit at their full brilliancy. In addition to the trials with incandescent lamps a large hand-regulated arc lamp was shown. This lamp did not work noiselessly, and must have proved a hard knot for the engine and machine. Notwithstanding the ordeal the magnet coils of the machine kept cool. We have so recently illustrated and described this machine that we have thought it preferable to enter somewhat into the details of the trial rather than to repeat our previous description.

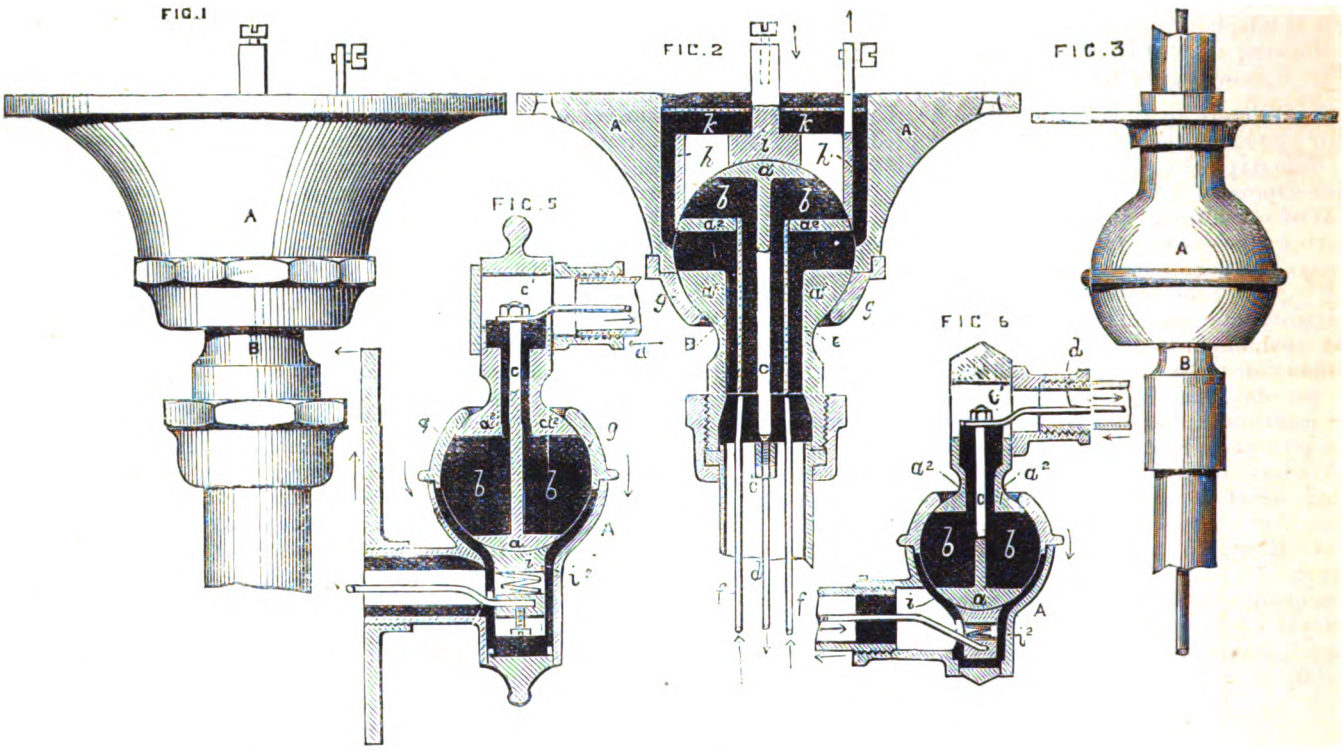
BREWTNALL'S SUSPENSION FOR ELECTROLIERS.

The object of this invention, by Mr. A. Brewtnall, of Streatham, is to enable the principle of the ball-and-socket joint to be applied to the suspension of electroliers and to the mounting of other swinging or movable fittings for the electric light by providing through the medium of this joint for the maintenance, unbroken, of the electrical circuit, when the electrolier or other fitting is swung or rotated. This is attained by constructing the ball, and its socket, in segments, of metal, separated from one another by segments, zones, or parts of insulating material, the metallic segments or portions of the socket corresponding to similar segments or portions of the ball, and in contact therewith over a sufficient extent of surface to permit of the free motion of the ball in its socket without breaking the electrical connection between the corresponding segments or parts.

The joint is illustrated in the accompanying engraving, in

Digitized by Google

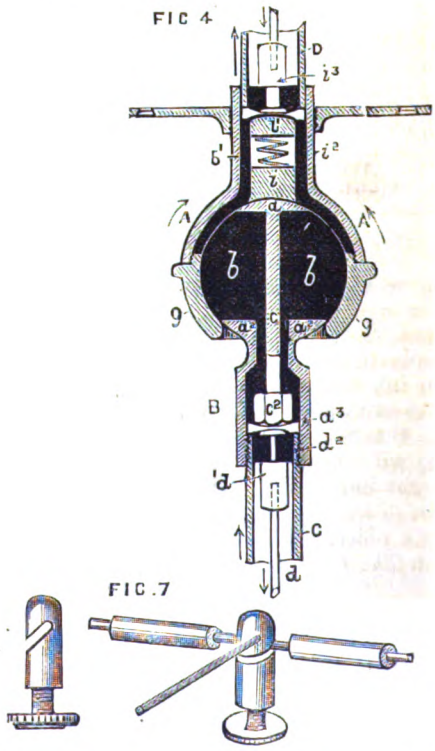
which Fig. 1 is an elevation, and Fig. 2 a central vertical section, of one arrangement of ball-and-socket for the suspension of an electrolier. In this arrangement the ball-and-socket are constructed of a sufficient number of zones or segments to afford a return circuit without using for this purpose the external metal of any part. Figs. 3 and 4 are similar views of a ball-and-socket in which the external metal is used for the return circuit. Figs. 5 and 6 respectively show the application of the ball-and-socket joint to the first and intermediate joints of wall brackets. In these figures



the arrangement is similar to Fig. 4, but the arrangement shown in Fig. 2 might equally well be employed if it is not desired to use the external metal for the return circuit. In all these figures the same letters of reference indicate corresponding parts.

A is the socket and B is the ball. In Fig. 2 the ball is composed of three horizontal metallic segments, a, a^1, a^2, separated from one another by two insulating segments b. The segment a is attached to a central stem c, which leads through the neck of the ball, and is connected by a nut, c, to the wire d leading to the lamp. To the intermediate metallic zone or segment a^1 is soldered a metal tube, e, which also leads through the neck of the ball and terminates in tangs, to which are connected the return wires f from the lamp. The segments b of insulating material are also carried through the neck of the ball and surround the rod c and tube e, and insulate them from one another, and from the third segment a^2. This third or lowest segment takes the wear, and rests in the corresponding gland g of the socket A. This third segment, a^2, serves for the attachment of the main stem of the electrolier in the ordinary way. This socket contains an annular metallic lining, h, which exactly coincides with the zone or segment a^1 of the ball, and is insulated from the outer portion of the socket, as shown. To this lining, h, the return wire is connected at h^1; i is a central stud, having its lower surface concaved to the radius of the ball, so as to make good contact with the uppermost segment, a, of the ball. To this stud the positive wire from the generator is attached, and the stud is insulated by a disc of vulcanite, and is pressed into contact with the segment a of the ball by a disc of soft india rubber, k, beneath the vulcanite, and bearing upon a shoulder of the stud. This india rubber disc, k, also bears at its edges upon the annular lining h, and presses it likewise into contact with the segment a^2. Thus it will be seen that there is perfect freedom for complete rotation, and also for oscillation to any desired extent, of the ball in the socket, without liability of breaking the electrical connection.

In Fig. 4 there are only two metal segments, a and a^2, separated by a segment, b, of insulating material, as shown. The segment a is attached to a central stem, c, as before, but the stem terminates in a nut, c^2, screwed on it, this nut being a sufficient distance within the socket a^3 of the part a^2 to enable the joint to be made as next described; d is the leading wire, fixed at its upper end into a stud, d^1, embedded in a plug, d^2, of insulating material, fitted into a coned seat in the end of the main stem C of the electrolier, from which the stud d^1 projects slightly, so that when stem C is screwed into



its socket, a^3, electrical connection will be made between c and d. The concave stud i, which presses on the segment a of

Digitized by Google

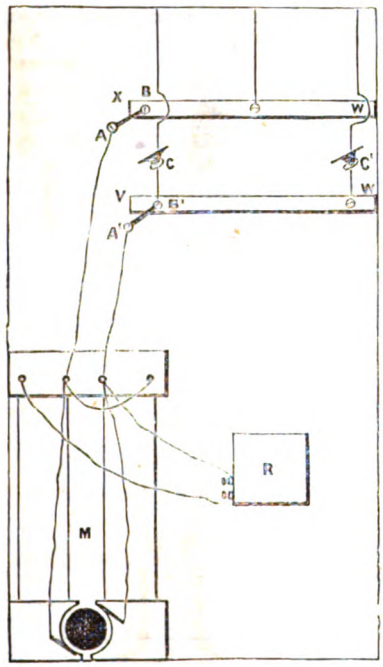
the ball is divided into two parts, i, i^1, connected by a metal spring, i^2, which answers the purpose of the india rubber disc k in Fig. 2. The joint of the leading wire from the positive pole of the generator is made by an insulated stud, i^3, pressed against i^1 in the act of screwing the tube D—which encloses said wire—to the socket A. In this arrangement it will be seen by the arrows that tube C, segment a^2 of the ball, gland g, socket A, and tube D serve as the return conductor. The tube D may be replaced when desired by a terminal.

Figs. 5 and 6 show the application of the same joint to the joints of wall brackets. The essential parts of the joint, being identical with those before described, need no further description, and the slight modification necessary in the bracket itself to adapt it to receive these joints will be apparent from the drawing without special explanation.

Fig. 7 shows one of Brewtnall's patent connectors for joining branch to main wires, slightly modified to suit the requirements of telegraph offices for connecting up the various instruments both on submarine and land lines. The drawings will sufficiently explain its use.—*Engineer*.

THE EDISON SYSTEM IN A SUGAR REFINERY.

An installation has recently been made by the Edison Company of Berlin in the sugar refinery of Messrs. Dannenbaum Brothers, in Warrenton (Braunschweig). The installation consists of eighty lamps, fitted up in the boiling room, crystallising room, mill room, &c. A new method has been adopted in this installation of connecting up the two main conductors with the different branches, which will be readily understood on reference to the following diagram. A B are safety catches, V W two copper bars, C C′ are switches, R regulating box, &c. This method renders testing a very easy matter. All the work, including the laying of 762 metres of underground cable, was completed in less than fourteen days, and gives entire satisfaction to the owners and superintendents of the refinery.



Edison Installation in Sugar Refinery.

Death of Madame Becquerel.—The death is announced of Madame Antoine Cesar Becquerel as having taken place at Chatillon-sur-Loing on the 27th February last, in her eighty-ninth year. She had only survived by five years her celebrated husband, the well-known electrician.

THE FUTURE OF ELECTRICAL ENGINEERING.

As a practical science it is only within the past few years that electricity has taken any permanent hold on the trade and development of the nation.

Its growth in this way has been slow, and the reasons for this are not very far below the surface.

Up to the invention, or, to speak more correctly, the practical application of the electric light, very small attention was given by any of the engineering profession to the subject, and the knowledge of electricity was confined to chemists and scientists, being looked upon by practical engineers as decidedly a laboratory question. The rapid development of the lighting powers of electricity, however, drew the attention of inventors first, and now of engineers, to the matter, and there is no reason to doubt that it is of the highest importance for the science and for the profession alike that they should become intimately connected with one another.

That this will be so, and that the mechanical engineers in the immediate future will hold the direction of electrical work, many facts go to show. It is particularly so with electric lighting. There is no scientific improvement in which the question of economy is so indispensable an item as in this, owing to the peculiarly trying competition to which it is subjected.

This economy, striking at the whole system, affects:—1st. the means of producing electricity; 2nd. the means of conveying it; and 3rd. the utilisation of it. Thus, whether the prime producer of electricity is a steam, gas, or water engine, their economy results from a due exercise of mechanical knowledge in their design, and, as electricity can only be produced in large merchantable quantities by such machinery, the engineers have a great—perhaps, the major—portion of the system under their present control.

The scientific man who has developed the principle of certain means of making or using electricity, must afterwards hand over this principle to more practical and mechanical minds for useful development. The dynamo or generator of electric force well illustrates this point.

The Gramme machine, which was the early inception of the principle, has, under the successive mechanical improvements since applied, become a working success even in the largest sizes, and no doubt, now that its lines of construction are clearly defined, many engineering firms will enter upon its manufacture, and reduce its cost by economies, and the use of special tools.

The transmission of the electric force is at the present time occupying the attention of scores of busy minds, and the scientific world generally is almost weekly anticipating the discovery of some great further step in this direction.

The check from which electric lighting has been for some months past suffering, although due in part to financial overexertion, is yet largely to be accounted for by the commercial failure of the accumulator or storage-battery, for the lack of which the trade is languishing, and in expectation of which, as an economical certainty, extensive electrical projects of supply are deferred.

It is a most fortunate circumstance for the needs of the world at large that the principle of the accumulation or storage of power was demonstrated when it was, as it has given to invention the basis on which to work, and it is not hard to estimate the annihilating difficulties with which the application of electricity would have been confronted without the promise of such assistance.

But it is in the *uses* of electricity that electricians, as distinguished from engineers, at present possess the greatest control; lamps, telegraphs, and telephones are of such delicate mechanism that their design and construction hardly fall within the province of manufacturing engineering, being more properly in that of instrument makers and clockwork.

Yet the question of economical production being of as vital importance here, as in the other portions of the body electric, engineering talent and mechanism must be employed increasingly to cheapen and multiply manufacture.

The blowing in glass of the globes of incandescent lamps is a case in point in which a move has been made.

Up to the present this work has been done by hand, but a

Digitized by Google

machine has been recently set to work, which forms these globes from a glass tube, not without the direction of a man, but by taking the work out of his hands and revolving, blowing, and heating under his control. Such a step is in the most necessary direction.

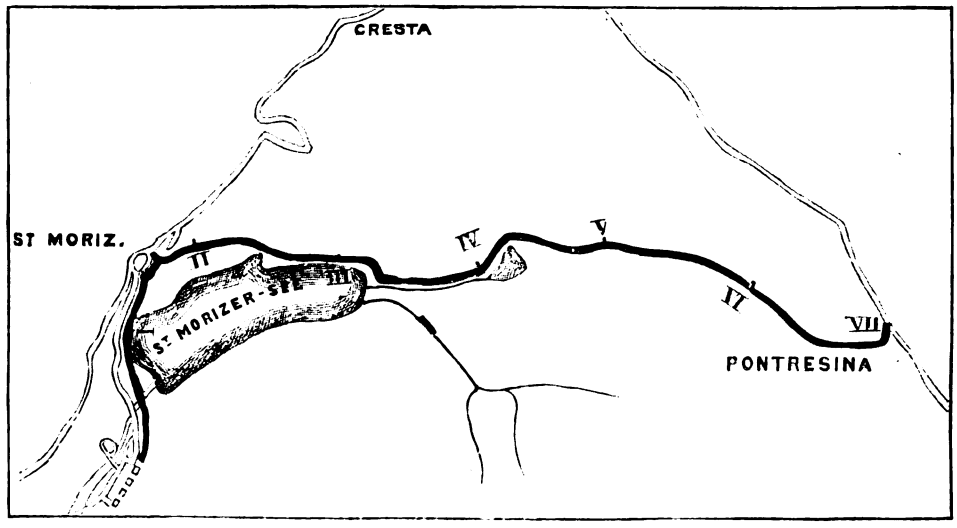
It is, perhaps, as a means of universally divided power, simpler, cleaner, more portable, and cheaper than fuel and steam, that electricity is hoped for by the general community. It is the realisation of this that will make electricity the "thing of the future," and give us the right to call ours the "electric age." That we are a distance from it, immeasurable because unknown, cannot be denied, and if it is to be accomplished it must be by engineering ability of the highest order.

The present is a period which admits of but one line of thought for a member of so varied a profession, but we have now, and shall increasingly possess, able minds among the scientific, military, and manufacturing engineers devoted to these subjects by duty or inclination.

Two great factors are operating to produce attention, namely, the prizes, which are great, and the competition, which each year grows greater.

AN ELECTRIC RAILWAY FOR SWITZERLAND.

A scheme is under consideration to establish, at an early date, an electric railway between St. Moriz and Pontresina,



Map showing the Route of the Proposed Electric Railway.

a distance of 7½ kilometres (4·6 miles), as part of a more extended scheme. Previous to the opening of the St. Gothard tunnel, traffic from Switzerland to Italy went *viâ* Coire and Chiavena, over either the Julian or the Splugen passes. The Swiss railway at present terminates at Coire, and next year the Italian railway system will be complete to Chiavena. The complete scheme is to join Chiavena with Coire by an electric railway by two routes. The distances are, from Coire to St. Moriz 76·5 kilometres, St. Moriz to Chiavena 48·8 kilometres, making a total of about 125 kilometres (77·5 miles). At present a concession is only asked for the St. Moriz portion, and it is stated that it is almost certain this will be granted to Herr Badruth. If this is successful a further concession will be asked for to the Engadine, and then over the pass to Chiavena. The district is well furnished with natural water-power, and it is proposed to utilise this water-power for the motive-power that will be required. We give a sketch map of the district, which no doubt is well known to many of our readers.

ELECTRICAL TRANSMISSION OF POWER IN MINES.

As the question of the transmission of power by means of electricity is engaging a great deal of attention just now, we think the following abstracts of two recent articles will be interesting. They are taken from *Abstracts of Papers in Foreign Transactions and Periodicals*, Vol. LXXI., Part I., published by the Institution of Civil Engineers.

The first is entitled "An Application of Electricity to the Transmission of Power at the Mines of La Péronnière," by Messrs. Charousset and Bague," and is abstracted from the *Bulletin de la Société de l'Industrie Minérale*, Vol XI., 1882, p. 5 :—

The energy in this case is transferred through conductors 1,200 metres (1,309 yards) long, from the mouth of the pit to the head of an incline 110 metres (120 yards) long, where it is employed to drive a windlass and draw the coal tubs up the incline. There are two generating dynamos and two receiving dynamos, connected by the four conductors so as to form two independent systems and circuits, of which it is not generally found necessary to employ more than one at a time. The connection between the Gramme dynamos and the driving machinery at one end, and between the dynamos and the intermediate gear of the windlass at the other end, take place by means of friction-pinions made of compressed paper. The machines ride upon a centre situated below each of their octagonal frames, and are kept up to more or less intimate contact by screws in the case of the generators, and by a system of levers, under the immediate control of the attendant, in the case of the receiving machines, care being taken to provide against excess of pressure by a stop. As these machines when receiving a current always run in the same direction, whatever may be that of the current, the intermediate gearing contains a system of conical sliding-pinions for reversing the motion of the winding-drum.

The four machines employed are all octagonal and similar to one another. The ring is divided into four parts, passing successively before as many magnetic poles, alternatively positive and negative. Each pole is formed by two coils whose cores are at right angles to each other, and have one pair of similar ends brought thus together.

The other ends of these eight cores are fixed in the octagonal frames, which therefore serves to connect opposite poles. Each of the four poles nearly completes the quadrant of a circle; and from the quadruple character of the magnetic field four brushes are necessary to each machine. The coupling is in series—that is, the entire current flows through

Digitized by Google

the electro-magnet coils of both the generating and the receiving machine.

The conducting cables are formed of sixteen copper wires of $\frac{11}{10}$ of a millimetre in diameter, the metal employed being perfectly pure. At the beginning of operations these wires, placed in juxtaposition, were first covered with a thickness of paraffined cotton, which again received two envelopes of cloth treated with Chatterton's compound, and was enclosed in india rubber and tarred. But, in spite of these precautions, the insulation did not remain perfect, on account of the damp situations in which parts of the cable had to be placed. A covering of lead was tried in damp places, but this turned out dangerous in practice, and the cables finally adopted were as follow:—

16 wires of copper $\frac{11}{10}$ diameter,
2 coats of paraffined cotton,
1 coat 5 millimetres thick of gutta percha,
2 windings of Chatterton cloth,
1 thick coat of tarred cotton;

and the purchasers themselves finally covered the cables with a paste of the following composition:—

57 pints of Norwegian tar,
38 „ resin,
5 „ suet,

in order to protect them, as well from heated gases as from damp.

The original cable, still maintained in the dry parts of the mine, cost 1·25 franc per metre; that finally employed in the damp situations, 3 francs per metre.

The trouble which arose before the question of the cables was finally settled was instructive. When the cheaper cable was employed for the whole circuit, the insulation in damp situations became defective in about one month. Shocks were received by the miners even through the rock in the neighbourhood of the conductors, and these shocks finally caused the rupture of the cables themselves. The nature of these ruptures was peculiar. The ends of the wires exposed were untwisted, and the surface had lost its polish, being honeycombed with little cavities filled with a brown, or sometimes black, dust. The paraffined cotton, which was very white when the cable was new, presented a green colour, and this discolouration extended to the exterior of the cable, and even to the walls of the pit. At four or five centimetres from the ends the wires were found to be intact. The oxide and carbonate of copper indicated a chemical action going on between the copper wires and the water in contact with the external envelope, under the influence of the electric current. It was on account of these ruptures that the lead covering was applied, but the safety of the cable was not found to be increased by this means. On one occasion the men below observed some large sparks in the pit, which greatly frightened them. The driver, warned by the galvanometer that something unusual was taking place, stopped the engine, and an investigation showed that the lead had been melted in several places, and thrown against the walls of the pit. Where the lead had been thus removed the Chatterton cloth was calcined, and the wires presented globules of metal which had been fused. All this occurred in a quarter of an hour, the receiving dynamo running free at the time. Since the application of gutta percha to the cables no such mishap has occurred. The following case of leakage occurred one day. The hauling cables, which are of iron wire, are attached to cast-iron projections on the drum, and by this means were in metallic connection with the bed-plate of the whole underground part of the installation. These cables were observed suddenly to be electrified, and at the same time a current passed through the telephone wire and set the bell ringing. Otherwise nothing abnormal took place in the running of the machinery. The phenomenon lasted two hours, during which it was impossible to touch the hauling cables without producing small disturbances, the effect increasing with the distance from the drum. On the bed-plate itself no shock was forthcoming.

The sudden disappearance of the phenomenon shows that it was due to some passing cause—perhaps to the presence of metallic dust on the india-rubber washers separating the bed-plate from the circuit traversed by the electric current; or, it may be, to the contact of one of the cables at a faulty point with the earth, for it was at that time that the cables began to show faulty insulation.

On a subsequent occasion a fault in the bottom insulation of one of the machines certainly caused a derived current, and the hauling cable, then no longer attached to the metallic framework of the drum, was electrified more strongly than on the previous occasion.

It is very necessary to keep the nuts which secure the brushes firmly in the sleeve or holder quite tight. The neglect of this once caused the loosening of the brush, with the generation of large sparks.

The needle of the galvanometer indicated a much stronger current than usual, and the steam engine was pulled up as if by a brake. The paper friction-gear became at the same time heated.

The following table gives the usual performance of these machines. It is based upon an average of experiments. The galvanometer used is simply a needle, placed over the conducting cables. It will be observed that its indications are proportional to the squares of the difference of velocities.

The second abstract is taken from an article by M. Graillot' in the same *Bulletin*. It is entitled "Experiments on the Transmission of Power by Electricity at the Mines of Blanzy," and reads as follows:—

These experiments were instituted in order to arrive at a knowledge of the efficiency to be expected in transmitting the energy of a steam engine above ground to machinery in the mine. The motor employed was a condensing Watt engine, without expansion, whose efficiency was assumed to be, during the experiment, constantly at 0·60. An intermediate shaft, with pulleys and belts, conveyed the motion of the engine to the generating dynamo.

The distance, 634 metres (= 691 yards), was represented by two coils of cable, each 604 metres long, and composed of nine copper wires $\frac{11}{10}$ millimetre in diameter, enveloped successively in cloth, in india rubber, and in lead. The remaining 30 metres (33 yards) were made up by a brass wire 5 millimetres in diameter. The receiving dynamo actuated the winding machinery by frictional contact with the intermediate gearing. The course of investigation adopted was to make a series of observations, by cylinder-diagrams, of the power necessary to drive the intermediate gearing alone at different velocities. This, reduced in the proportion of 10 : 6, was in each case deducted from the power (reduced in an equal ratio) required in the various experiments with loads. The balance was taken to be the power transmitted to the

Digitized by Google

generating dynamo, and this is finally compared with the useful work done by the windlass in weight raised.

The results obtained are open to the criticism, passed upon them indeed by Mr. Rossigneux, that they rest upon the assumption of the constancy of the efficiency co-efficient of the steam engine under differing loads; but the results obtained are valuable, as showing the variation in the useful work when the other conditions remain fairly uniform, and as qualifying the dogma that as the work given out diminishes the efficiency increases. The length of the conductors within the limits (634 metres and 30 metres) of these experiments seemed to have no sensible influence upon the efficiency. When the work to do was small the efficiency was small, and rose as the work approached in value that for which the machinery was designed. Thus, with the long conductors, when the work utilised was 0·73 h.-p., the efficiency was 17·25 per cent.; at 1·15 h.-p. it varied between 26 and 34 per cent.; at 2 and 2½ h.-p., between 40 and 51 per cent.; and at 3½ and 4 h.-p., between 37½ and 51 per cent. With the short conductors, at 1½ h.-p. of useful work, the efficiency was 28 per cent.; and at 2 and 3 h.-p. it varied from 40 to 51½ per cent.

LITERATURE.

Electric Illumination. Engineering Series. Edited by James Dredge.

The time has come when the public, as well as engineers and inventors require a systematic account of the apparatus employed in electric lighting, to enable them to select the most suitable, as well as to see what has been done and what is required to be done. As yet this information is only to be gathered from a multitude of scattered papers and a few small works of a partial and incomplete character. This work, which has space enough to promise something to its readers, and comes from a source which may be expected to supply abundant material, will therefore be received with some interest. Being the work of several writers it must be expected to be unequal in character, nor can a perfect consistency of treatment be looked for.

The chapter on electrical units with which the work opens is singularly disappointing, to use a mild expression. There already exists sufficient misapprehension as to the various units, owing to the complication introduced by the C.-G.-S. system, which has been so much employed after the original definitions of the units had become familiar under the simpler metre-gramme-second system employed by the original committee. The needless changes of names made by the Paris committee will add to the difficulties of future students by making the books already published mislead them, and in this chapter we have a guidance through the difficulties of much of that order which is calculated to place the proverbial traveller "in the ditch."

Speaking of the *erg* as having the practical fault of being too small, after saying "this difficulty was met by devising a second unit, the meg-erg, equal to one million ergs," we have the astounding information, "a minor unit, the erg-ten, equal to 10 ergs, was also introduced. This Mr. W. H. Preece suggested should be called a watt!" The genial face of Mr. W. H. Preece must have been worth seeing when he read this; however, he likes a joke, and, in the requisite selection of language fitted to express his feelings, he may have pitched upon George the Third's favourite exclamation—What! what! Certainly, whatever an erg-ten may be, it is not a watt. It is usually supposed that the barbarous term means erg $\times 10^{10}$, or ten thousand million ergs, which is rather inversely a minor unit. The watt is 10^7 ergs.

The chapter is made up of extracts from various reports, with definitions such as "*Electromotive Force*, or that mysterious power which tends to produce a transfer of electricity from one point to another of a conductor," and "*Capacity*, or the quantity of electricity necessary to raise the potential of a conductor from zero to unity." But there is nothing to convey to the mind any theoretical or practical conception, either of the individual units or their systematic relations, so that the utility or purpose of this chapter is somewhat doubtful.

A description follows of instruments for measuring and recording electric currents, such as the galvanometers of Deprez and of Ayrton and Perry, and the meters of Edison. Of the latter it is said that they "are a remarkable example of originality of invention;" but although the Weber-meter, to which the remark especially relates, is twice figured and described, nothing is said of the identical device patented two years earlier by Mr. Sprague, and which is also omitted from the classification of inventions under the head of "Current Meters," although the patent containing it appears under several other headings. Nor is there any description of the meter of Mr. Boys (beyond its mention in the list of patents) or of any other mechanical or integrating meter except that of Mr. Lane-Fox.

The chapter on the "Mechanical Production of Electric Currents" gives very clear and good explanations of the principles which govern the relations of electric current and magnetism. The early part of the chapter is especially instructive, though it may be doubted whether the writer does not dwell too strongly upon the idea "that the energy of a current is to be conceived as existing in the space *outside* the wire quite as much as in the wire itself." It is beyond question that the habit of considering the conductor alone as concerned in the development and transmission of current has led electricians to overlook important facts which play an essential part in dynamo electric machines; it is, therefore, proper to bring these facts prominently before the reader, and to show their importance. But it is going as far wrong in the opposite direction to assert, as the first fundamental principle, "That the existence of the energy of electric currents, and also the energy of magnetic attractions, must be sought for, not so much *in the wire* that carries the current, or *in the bar* of steel or iron that we call a magnet, as in the space that surrounds the wire or bar." After all, the substance, the "bar," is the material basis of the magnetic field; it is rather too metaphysical to talk of the solid magnet as merely a "convenient conductor for the lines of force," seeing that these lines of force only exist where there is this material basis to rest upon. Still more fallacious is it to reason about electric currents and their magnetic actions "quite irrespective of the copper wire, which acts as a conductor," seeing that without that wire the forces and actions have no existence. But the classification of the different systems of machines and the theories of the ring, drum, pole, and disc armatures, and the illustrations of the reactions of magnets and currents will atone for some little wandering in the dreamlands of science.

The chapter on the theory of dynamo electric generators is largely based upon the experimental researches of M. Breguet, and deals entirely with the reactions in the Siemens and Gramme armatures in connection with a theoretical examination of the influences operating upon a wire rotating in a magnetic field. But the core of the Gramme ring is treated only as a "magnetic shield," as preventing the inverse action of the lines of force upon the inner layers of wire, and to a small degree as deflecting and reversing the direction of these lines upon the edges and inner side of the ring, so as to convert the inverse into a direct action. No account appears to be taken of the effect of the opposite pole induced in the ring, or of the action of the ring itself upon the wires. This appears to be a very incomplete treatment of the subject, for it is very certain that the direct action of the wires cutting the lines of force of the field magnets is but a portion, and probably a small portion, of the action in the Gramme machine. This subject is, however, dealt with again in the special description of the Gramme machine itself, where it is stated that the core acts as if it were two semicircular magnets acting as though "the iron portion of the ring were fixed, and the coils of surrounding wire were caused to run round it." But this is treated as subordinate to a more important effect. The following sentence describes, or is intended to describe, this more important effect:—"As the lines of force constituting the magnetic field of the two magnets form a series of elliptic arcs joining their two poles (as we have already seen), it

Digitized by Google

follows that not only does a large proportion of those lines of force with the ring, thereby causing it to become strongly magnetic, but the convolutions of the induction coils, attached as they are radially to the ring, are moved during its rotation within the magnetic field in directions perpendicular to a large percentage of those lines of force, and therefore in a way specially advantageous to the induction of magneto-electric currents." This is difficult to comprehend, and the probable explanation of its mystery is that some words have been dropped which are necessary to complete the sense. So far as it is comprehensible it would appear to relate to the reaction of the core upon the wire as a magnet traversing a coil. This is in fact the meaning apparently conveyed by a diagram which follows; but this can scarcely be the true meaning, as it would be a direct repetition of the action just treated as of less importance.

Perhaps the most interesting part of this chapter is the explanation offered of the necessity for displacing the commutator brushes of machines to an extent varying with the rate of rotation. This is usually attributed to the action of the iron, which requires time to take up and part with its magnetism. On this the author says: "The presence of the iron ring exercises two influences quite distinct from one another. Firstly, since it requires time to magnetise or demagnetise it, it will necessitate that the contact brushes be displaced a little in advance of their theoretical position, or with an increased lead. This displacement, always in the sense of rotation, will, therefore, diminish the total displacement when the machine is used as a motor, but will increase it when used as a generator. In either case, however, its influence is quite small. Secondly, the presence of the iron ring increases the intensity of the magnetic field, concentrating a greater number of lines of force in it, and, therefore, tending to reduce the deformation in its symmetry. This is a most important influence, and it will be seen that in the case where the machine is used as a generator the presence of iron in the armature tends to bring back the most favourable position of the contact brushes towards the position of symmetry, that is, tends to *diminish* the angular displacement which must otherwise be observed. The action of the iron of the ring is, therefore, absolutely the contrary to that commonly attributed to it, for, so far from necessitating a displacement of the contact brushes in the direction of the rotation, it absolutely serves to diminish the angular displacement necessitated by the dissymmetry of the magnetic field." The explanation offered in exchange for that commonly received is, that the main line of force in the magnetic field is not the axial line between the poles N——S. The actual magnetic field, in any case, is, of course, a resultant of all the forces operating in it, and the presence of a magnetic body or an electric current at once deranges the normal lines of a field and sets up new conditions, in which the added force takes a part. It is calculated that the presence of the moving conductor, carrying a current, does in this way disturb the axis of the field, and change it from N——S to N⌒S; this ⌒-like distortion increasing with the velocity of rotation. The true line of commutation, being at right angles to the axis of the field, is, therefore, displaced more and more as the velocity of rotation increases; and it is contended that the iron, instead of causing this displacement, reduces it by concentrating the shortened lines of force upon its surface where closest to the poles of the field magnets. It would be interesting to know whether a Gramme ring without an iron core would really show greater displacement of the brushes than it does with the core.

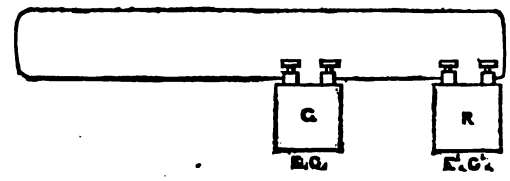
(TO BE CONTINUED.)

THE EDISON SYSTEM IN BRUNN.—We are informed that the Edison Company are starting a small lamp factory in Brünn, Austria, under the management of Mr. Francis Jehl, who, as our readers are aware, is in charge of the installation at the new theatre there.

THE TRANSMISSION OF POWER BY MEANS OF ELECTRICITY.*

Ever since the experiments of MM. Chrétien and Félix at Sermaize, an account of which I gave to the Academy at its meeting on the 26th May, 1879, and those of M. Fontaine at the Vienna Exhibition in 1873, I have been endeavouring to find an installation by means of which I could ascertain all the electrical and mechanical *data* referring to the transmission of power by means of dynamo-electric machines. The varied conditions of the first experiments mentioned above were far different from those of the experiments which have for some time past occupied the attention of the Academy, and M. Marcel Deprez having requested me to be good enough to make the requisite calculations, I at once readily assented, the consequence being that I can now present to the Academy a very complete report of the experiments which took place on the 11th of February, the substance of which I am satisfied is accurate, and for which I assume all responsibility.

The telegraph wire of ·004 metre diameter over which the current was transmitted offered a resistance of 160 ohms; its total length, from Paris to Bourget, together with the return, was 17,000 metres (about 18,133 yards), but the other poles of the machines were connected by a short wire. (A diagram of the method of connecting the machines is given herewith.) The conditions of working, losses being taken into account, were comparable to a hypothetical case in which the two machines might be considered as situate, relatively to one another, at a distance of 8,500 metres only (about 9,066 yards), and connected by a double wire, lead and return.



Arrangement of Machines in M. Deprez's Experiments.

The generating machine, as far as its armature was concerned, was of a particular design introduced by M. Deprez, having a double bobbin and wire of 1 millimetre diameter ($\frac{1}{25}$in.); the receiver was a large Gramme machine, army type, modified for the work it was intended for. The resistances of these two machines were respectively 56 and 83 ohms. During each experiment the number of revolutions per minute made by each machine was determined simultaneously by means of special counters. All the electrical measurements were made by Dr. J. Hopkinson, F.R.S., with Sir William Thomson's apparatus. They agreed very exactly with the figures obtained previously by M. Deprez with the aid of his own apparatus.

The measurements of the difference of potential between the two poles of each of the machines were made with a Thomson galvanometer, a supplementary resistance of 50,000 ohms being employed. The current measurements were made by means of another Thomson galvanometer, through which the whole current was made to pass. The magnets of both these instruments, after having been tested in London on the 9th February, were again examined on the 13th February, on their return from Paris, and it was ascertained that they had undergone no change; each division of the potential galvanometer corresponded to 50·7 volts., and each division of the current galvanometer to ·223 ampere.

General Morin's dynamometer, with rotating dials, lent for the occasion by the Conservatoire des Arts et Métiers, was used for the measurement of the motive power, and connected to the generating machine by an intermediate shaft.

The experiments were made under conditions which showed that no slip to speak of had failed to be taken into account. The motive power was measured by diagrams in which each millimetre of ordinate represented an effort of 8·80 kilograms, the path travelled per revolution being $\pi \times \cdot 835 = 2 \cdot 623$ metres. The effective work at the shaft of the receiver was constantly measured by a Prony brake, perfectly balanced, the lever arm of which had a horizontal length L = ·796 metre, corresponding to a travel of 5 metres per revolution. This lever being uniformly weighted with 5 kilograms, the work was calculated on the basis of 5 kilogrammetres per revolution (about 36ft.-lbs.).

Seven successive experiments were made under the conditions above mentioned. Only one diagram—that of the last experiment—failed me; and, in addition, I measured the work ex-

RETURNS.								
Of the generator (in electric power)	0·734	0·715	0·624	0·728	0·719	0·763	4·283	0·712
Of the circuit (in electric power)	0·715	0·707	0·721	0·697	0·670	0·712	4·212	0·706
Of the receiver (in mechanical power)	0·671	0·610	0·707	0·642	0·625	0·640	3·895	0·651
Between the two ends of the circuit	0·348	0·318	0·317	0·326	0·302	0·348	1·959	0·326

* The resistance of the line, calculated at 160 ohms for a current of 2·559 amperes, represents a work of 1·42 horse-power.

pended in mechanical transmission between the dynamometer and the generating machine by an eighth dynamometrical measurement. The speed was then greater than during the other experiments. However, I only deducted the work expended per revolution, so as to be able at once to calculate its influence in each of the preceding experiments. In Table I. are collected all the data, as well as the averages to be calculated therefrom. The mechanical work was calculated in horse-power on the basis of 75 kilogrammetres per second; but I should remark that the electrical work was calculated by Dr. Hopkinson from direct galvanometer measurements, and taking one horse-power as equal to 76 kilogrammetres. Despite the slight inaccuracy which results from this, it has seemed better to me to let the figures arrived at by the English observer stand without alteration.
